  2. The CDC recommends that those who received Zostavax be revaccinated with Shingrix.
  3. Those who have had HZ should still receive the vaccine.

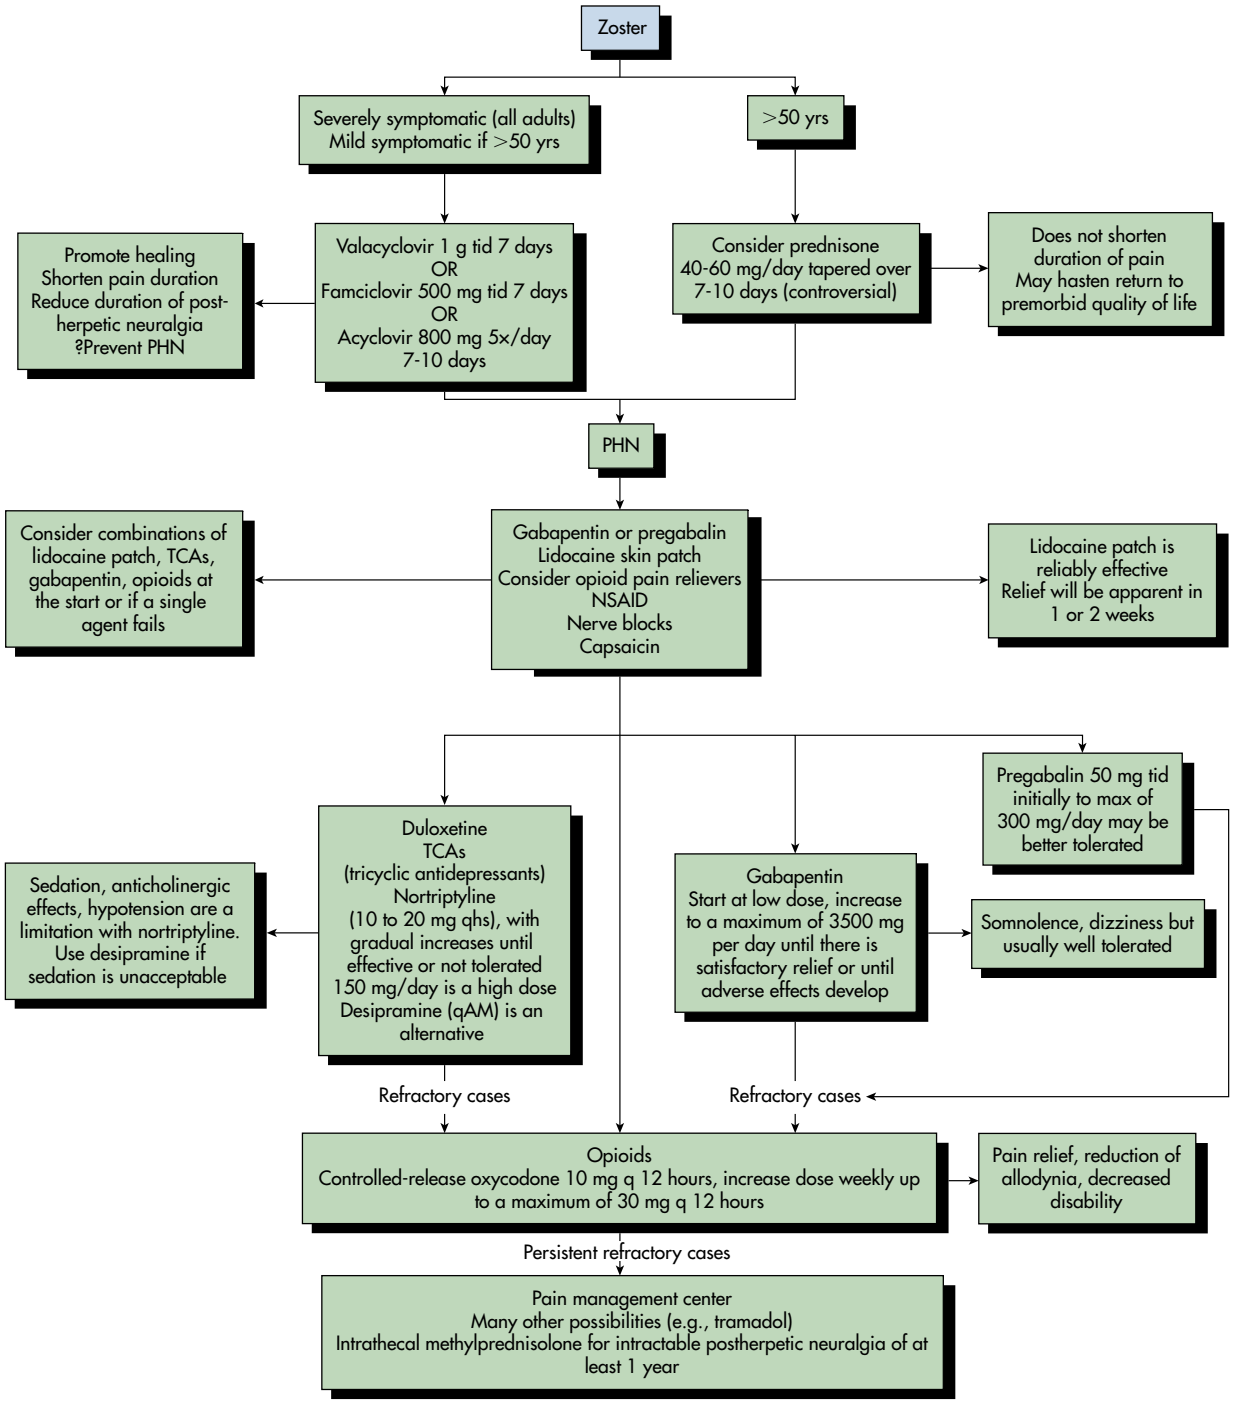

FIG. 1 Treatment of herpes zoster and postherpetic neuralgia. *NSAID,* Nonsteroidal antiinflammatory drug; *PHN,* postherpetic neuralgia. (Modified from Habif TA: *Clinical dermatology,* ed 6, St Louis, 2016, Elsevier.)

PATIENT & FAMILY EDUCATION

- The only well-documented means of preventing PHN is the prevention of herpes zoster through vaccination.
- Patients should understand both the benefits and the potential adverse effects of treatment.
  1. They should be informed that pain relief will likely not be immediate.
  2. Frequent reassessment may be needed, and drug doses should be increased as necessary.

BASIC INFORMATION

DEFINITION

Major or minor depressive episodes that are severe enough to affect activities of daily living and occur most commonly within 1 to 3 wk after delivery but can also present up to 12 mo postpartum.

SYNONYMS

Spectrum of disease presentation
Postpartum blues
Postpartum depression
Postpartum psychosis

ICD-10CM CODES

F53	Includes postpartum depression and postpartum psychosis
090.6	Includes postpartum blues, postpartum dysphoria and sadness

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Approximately 800,000 women who deliver in the U.S. or 20% of all live births are affected by postpartum depression annually.
PREVALENCE: Perinatal depression affects approximately 10% to 15% of women.
RISK FACTORS: Risk factors include depression or anxiety during pregnancy, traumatic birth experiences, stressful life events during pregnancy or the postpartum period, infant NICU admission or preterm delivery, poor social support, history of depression, and problems with breastfeeding.
GENETICS: A family history of mood disorders is a risk factor for postpartum depression.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients present with depressed or irritable mood, decreased interest in activities, appetite and sleep changes, weight changes, decreased energy, excessive guilt or feelings of worthlessness, psychomotor agitation or retardation, and possibly suicidal/homicidal ideation. The diagnosis of major depressive episode requires that symptoms be present nearly every day for 2 wk and that the woman experiences a decline from a previous level of functioning.

ETIOLOGY

The decline in reproductive hormones following delivery is believed to contribute to the development of postpartum depression in some women. In addition, women with a history of depression, premenstrual syndrome or dysphoric disorder, stressful life events, and a family history of mood disorders have an increased risk of both depression and postpartum depression.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hyperthyroid
- Hypothyroid
- Postpartum blues: Syndrome involving symptoms of depression, anxiety, or anger that usually occurs 2 to 3 days after delivery and resolves within a few days to 1 to 2 wk postpartum without treatment
- Postpartum psychosis: Usually occurs between 1 to 2 wk post delivery and is characterized by extreme disorganization of thought, hallucinations, and bizarre behavior. It requires rapid intervention, as there is a real risk of suicide or infanticide
- Bipolar disorder

WORKUP

- History and physical examination
- Screening all postpartum women with a screening instrument such as the Edinburgh Postnatal Depression Scale (specific to the postpartum period and takes less than 5 min to complete) or the Patient Health Questionnaire-9
- In any patient with postpartum depression, screening for bipolar disorder

LABORATORY TESTS

Thyroid screening tests (if high suspicion for thyroid disorder)

TREATMENT

NONPHARMACOLOGIC THERAPY

Psychotherapy: Studies have shown psychotherapy to be equally effective to fluoxetine.

ACUTE GENERAL Rx

- Therapy with a selective serotonin reuptake inhibitor should be considered as first-line treatment because of low risk of toxic effects with overdose and ease of dosing. However, if the patient has had good success with another medication in the past, then it is appropriate to restart that medication. Start at half the recommended dose and increase after 4 days, with gradual up-titration until therapeutic effects are seen.
- A single medication is favored over multiple medications in order to decrease exposure to the fetus/neonate.
- Sertraline is the first-line selective serotonin reuptake inhibitor recommended for breastfeeding mothers secondary to existing evidence suggesting little risk for infants. There is, however, no evidence of adverse infant effects from mothers taking sertraline, paroxetine, or fluvoxamine. Fluoxetine may be present in higher levels in breast milk and breastfed infants.
- Tricyclic antidepressants do not appear to pass in significant amounts into breastfeeding infants and their use appears to be safe. Data regarding atypical antidepressants and breastfeeding are limited.
- The FDA recently approved an IV infusion of the drug brexanolone (Zulresso). It is administered as a single 60-hour IV drip and is currently only available to patients through a restricted distribution program at certified health care facilities.

CHRONIC Rx

- Medical therapy should be continued until at least 6 mo after remission.
- Long-term therapy should be considered for women with a history of three or more episodes of depression.

DISPOSITION

- Without treatment, the duration of postpartum depression averages 7 mo.
- 15% to 85% of women will experience at least one relapse after completing medical therapy.

REFERRAL

- Consider referral to psychiatrist if a patient demonstrates no improvement after 6 wk of drug therapy or experiences a relapse.
- Prompt or urgent referral to psychiatrist is indicated if a patient has signs/symptoms of postpartum psychosis, bipolar disorder, or expresses suicidal/homicidal ideation.

PEARLS & CONSIDERATIONS

COMMENTS

- Depression and anxiety both during and after pregnancy can have negative effects not only on the mother but also on her fetus, new baby, and family. Low birth weight, decreased fetal growth, increased NICU admission rates, increased neonate crying, and decreased developmental scores have been seen with these disorders when untreated. In addition, depression is associated with increased smoking, alcohol, and drug use, which can have negative effects on the infant and family. These factors should be taken into account when counseling women about medical therapy.
- Selective serotonin reuptake inhibitors do pass through breast milk but are present in very small quantities compared with the transplacental exposure infants receive in utero. Adverse infant effects are extremely rare; however, long-term data are lacking.

PREVENTION

In a patient with a history of postpartum depression, recurrence risk is approximately 25%. These patients should be screened for depression both during and after pregnancy. It is reasonable to initiate prophylactic therapy in patients with a history of depression, and they should have close postpartum follow-up for early identification of depressive episodes.

Postpartum Hemorrhage

BASIC INFORMATION

DEFINITION

Postpartum hemorrhage (PPH) is defined, for both vaginal and cesarean deliveries, as an estimated blood loss ≧1000 ml OR blood loss resulting in signs/symptoms of hypovolemia within 24 hr following delivery. PPH is further categorized into primary or secondary. Primary PPH occurs within the first 24 hr after delivery. Secondary PPH occurs >24 hr after delivery but within 12 wk following delivery.

SYNONYMS

Obstetric hemorrhage
Maternal hemorrhage
PPH

ICD-10CM CODES

O72.0 Third stage hemorrhage
O72.1 Other immediate postpartum hemorrhage
O72.2 Delayed and secondary postpartum hemorrhage
O72.3 Postpartum coagulation defects

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Depending on definitions used and scope considered, anywhere from 1% to 6% of obstetric patients will experience postpartum hemorrhage. Postpartum hemorrhage is the leading cause of maternal mortality worldwide and is implicated in >10% of maternal deaths in the U.S.
PREDOMINANT SEX AND AGE: Female of reproductive age
RISK FACTORS: Antepartum factors: History of PPH, primiparity or high parity, macrosomic infant, multiple gestation, polyhydramnios, uterine fibroids, prior uterine surgery, abnormal placentation, bleeding disorder

Intrapartum factors: prolonged labor, augmented labor, rapid labor, preeclampsia, chorioamnionitis, operative delivery, episiotomy, lacerations, retained products, placental abruption, fetal demise

PHYSICAL FINDINGS & CLINICAL PRESENTATION (TABLE 1)

- Bleeding is generally brisk at time of delivery.
- Examination findings include boggy uterus with continued passage of clot or blood with fundal pressure.
- Objective findings can also include hypotension, tachycardia, and oliguria with substantial blood loss.

ETIOLOGY

- Primary: Uterine atony (70% to 80%), retained placenta, lacerations and coagulopathies
- Secondary: Subinvolution of placental site, retained products (includes abnormal placentation), infection and coagulopathies

DIAGNOSIS

WORKUP

- Bladder should be emptied
- Bimanual examination to evaluate for atony; remove clots; massage if it is present
- Examination to verify that no lacerations are present, including cervical examination with necessary lighting and retractors
- Ensure adequate IV access
- Ultrasonography at bedside to evaluate for retained tissue or clot
- Examination to verify that placenta is intact

LABORATORY TESTS

Significant hemorrhage can lead to disseminated intravascular coagulation (DIC). If DIC is suspected, complete blood count and coagulation panels should be ordered. Similarly, if coagulopathy is suspected, evaluation of clotting factors should be ordered.

IMAGING STUDIES

Ultrasonography can be used to scan for retained products, including clot or placenta. It can be performed to assess the need for more invasive measures, such as instrumentation or a manual sweep.

TREATMENT

The most effective strategy for the prevention of postpartum hemorrhage is active management of the third stage of labor (AMTSL). Medical management with uterotonics is generally the first line of treatment:

- Oxytocin (IV, 10 to 40 units diluted into IV solution, or 10 units IM); often given prophylactically immediately after delivery to minimize EBL with delivery of placenta
- Methergine (IM, 0.2 mg)—contraindicated in hypertensive patient
- Hemabate (IM, 0.25 mcg)—contraindicated in patient with history of asthma
- Misoprostol (400 to 800 mcg sublingually, buccally, or rectally)

Other medical management:

- Tranexamic acid (IV, 1 g)

NONPHARMACOLOGIC THERAPY

- Active management of third stage of labor: controlled cord traction (Brandt-Andrews maneuver) and uterine massage after delivery of placenta
- Uterine tamponade (Fig. E1): Packing with gauze, Foley catheter, or tamponade balloon (Bakri)
- Uterine curettage for suspected retained products
- Uterine artery embolization
- Surgical management with laparotomy:
  1. Hypogastric artery ligation
  2. Bilateral uterine artery ligation (O'Leary sutures)
  3. B-lynch sutures
  4. Hysterectomy

ACUTE GENERAL Rx

- Uterotonics, surgical management, embolization, blood transfusion. Fig. 2 outlines the management of postpartum hemorrhage.
- Table 2 describes therapeutic response to initial fluid resuscitation. Dosing regimen for oxytocic drugs is summarized in Table 3. Blood product replacement is described in Box 1.

CHRONIC Rx

For anemia (Hb <10 g/dl) – Ferrous sulfate and ascorbic acid supplementation to support new red blood cell production

DISPOSITION

- The patient should be closely watched for at least 24 hr after a postpartum hemorrhage. Vital signs should be monitored for evidence of hemodynamic stability and appropriate response to anemia. Serial laboratory tests can be performed in the setting of concern for ongoing bleeding.
- Morbidity can include: shock, acute respiratory distress syndrome, Sheehan syndrome, thromboembolic disease, and loss of fertility.
- For cases with large blood loss (e.g., >2 L) and hemodynamic instability, intensive care unit admission may be warranted.

TABLE 1 Presentation of Symptoms in Postpartum Hemorrhage

% Blood loss (ml)	Systolic blood pressure (mm Hg)	Signs and symptoms
10-15 (500-1000)	Normal	Tachycardia, palpitations, dizziness
15-25 (1000-1500)	Low-normal	Tachycardia, weakness, diaphoresis
25-35 (1500-2000)	70-80	Restlessness, pallor, oliguria
35-45 (2000-3000)	50-70	Collapse, air hunger, anuria

From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.

TABLE 2 Therapeutic Response to Initial Fluid Resuscitation

Response	Description	Follow-up treatment
Rapid response	<20% of blood volume lost	No additional fluids or blood are needed.
Transient response	20%-40% of blood volume lost; responds to initial fluid bolus but later has worsening vital signs	Continue fluids and consider blood transfusions.
Minimal or no response	Ongoing severe hemorrhage with >40% blood volume lost	Continue aggressive fluid and blood product replacements.

From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.

TABLE 3 Dosing Regimens for Oxytocic Drugs

Drugs	Regimens
Oxytocin (Pitocin)	5-unit IV bolus
	Add 20-40 units oxytocin to 1 L of fluids for continuous infusion
	10 units intramyometrially
Methylergonovine (Methergine)	0.2 mg IM every 2-4 h
Ergonovine maleate (Ergotrate)	100-125 μg IM or intramyometrially every 2-4 h
	200-250 μg IM
	Total dose 1.25 mg
Carboprost (Hemabate)	250 μg IM or intramyometrially every 15-90 min
	Total dose 2 mg (8 doses maximum)
Misoprostol	800-1000 μg PR, oral, or sublingual

IM, intramuscular; *IV,* intravenous; *PR,* per rectum.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

BOX 1 Blood Product Replacement

Crossmatched blood.
Type-specific or "saline crossmatched" blood.
Compatible ABO and Rh blood types.
Rh-negative blood is preferable.
- Warm the blood, if possible, especially if the rate of infusion is >100 ml/min or if the total volume transfused is high; cold blood is associated with an increased incidence of arrhythmias and paradoxic hypotension.
- Administer calcium if blood is transfused rapidly at >100 ml/min because of binding of calcium by anticoagulants in banked blood.
- Give 6-10 units fresh frozen plasma (FFP) for every 10 units of packed red blood cell (PRBC) transfusions.

Give 10-12 units of platelets if the platelet count decreases to $<50 \times 10^9$/L.
Cryoprecipitate can be given to replace fibrinogen in addition to the FFP.
Consider 60-120 μg/kg intravenous bolus injection of recombinant activated factor VII (rFVIIa).

From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

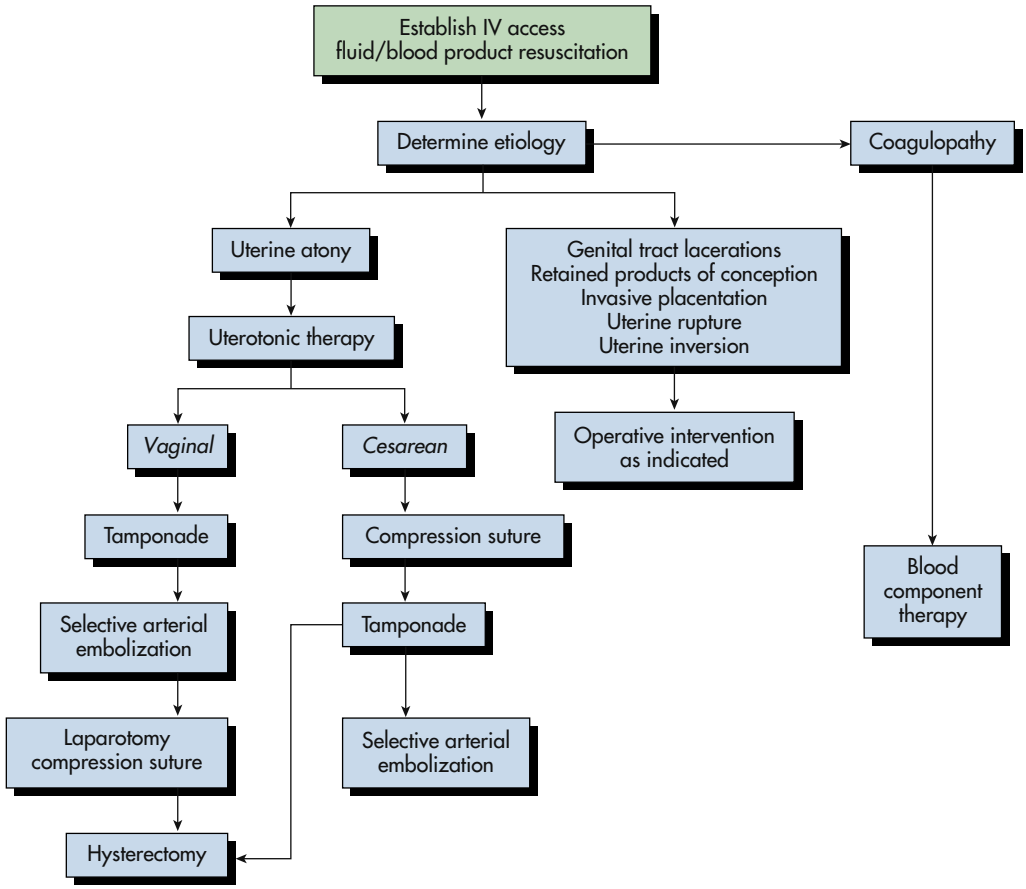

FIG. 2 Management of postpartum hemorrhage. (From Gabbe SG: *Obstetrics,* ed 6, Philadelphia, 2012, WB Saunders.)

REFERRAL

During the course of a postpartum hemorrhage, the anesthesiology department, blood bank, and OR staff should be notified, and adequate nursing should be available. Early considerations should be made to notify obstetricians. If bleeding is brisk or estimated blood loss is considerable, preparation should be made for transfusion of blood products, including drawing blood for typing and notifying the blood bank.

PEARLS & CONSIDERATIONS

PREVENTION

- Active management of third stage of labor
- Implementation of institution-specific PPH risk assessment tools effective for identifying patients at increased risk, though clinical suspicion should be maintained in all patients

Postpoliomyelitis Syndrome

BASIC INFORMATION

DEFINITION

Postpoliomyelitis syndrome (PPS) is a disorder typically characterized by the gradual onset and slow progression of new weakness, fatigue, and pain in survivors of paralytic poliomyelitis after a period of partial or complete recovery and many years of neurologic stability. The symptoms are persistent and cannot be explained by the presence of other neurologic, medical, or orthopedic conditions.

SYNONYMS

PPS
Post polio syndrome
Progressive postpoliomyelitis muscular atrophy

ICD-10CM CODES
G14 Post polio myelitic syndrome
B91 Sequelae of poliomyelitis
Excludes 1: Sequelae of poliomyelitis (B91)

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Estimates vary from 22% to 85% of individuals who survive acute poliomyelitis.
PEAK INCIDENCE: About 30 to 36 yr following acute poliomyelitis, although cases have been reported between 8 and 71 yr.
RISK FACTORS:
- Increasing age and greater length of time since the episode of acute poliomyelitis
- Acute poliomyelitis at an older age
- Greater severity of the acute poliomyelitis, especially with respiratory involvement or chronic deficits after recovery

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The most common clinical features are new weakness (20% to 60%), fatigue (59% to 89%), and pain (38% to 86%).
- The symptoms typically have an insidious onset with gradual progression.
- The new weakness is typically, but not exclusively, in muscles that were previously affected by the acute poliomyelitis.
- Fatigue may be described as either general or muscular in nature and is often the most disabling symptom.
- Pain is usually described as severe aching, cramping, or burning localized to the muscles or joints, particularly in areas previously affected by acute poliomyelitis.
- Respiratory weakness and sleep-disordered breathing with nocturnal hypoventilation occur less frequently.
- Other less common features include fasciculations, dysphagia, dysarthria, and cold intolerance.
- Neurologic examination reveals evidence of asymmetric, lower motor neuron weakness with or without musculoskeletal deformities secondary to longstanding polio such as asymmetric limb size, kyphoscoliosis, degenerative joint disease, and joint instability.

ETIOLOGY

The pathophysiologic basis of PPS remains unclear, although there are several proposed mechanisms. The most popular hypothesis is that the reduced population of enlarged motor units after acute poliomyelitis is subject to increased stress and overuse over the course of years. This leads to distal degeneration of the motor units and worsening denervation, causing clinical symptoms.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

PPS is a diagnosis of exclusion. A particular individual's symptoms will determine the differential, but some commonly considered entities are:
- Amyotrophic lateral sclerosis (ALS)
- Cervical or lumbosacral radiculopathy
- Acquired demyelinating polyneuropathies
- Myasthenia gravis
- Fibromyalgia
- Chronic fatigue syndrome
- Anemia
- Hypothyroidism
- Arthritis
- Depression
- Normal aging

WORKUP

- A detailed history should confirm a past history of acute poliomyelitis followed by a period of stability prior to emergence of the new symptoms.
- A neurologic exam confirms weakness of the lower motor neuron pattern.
- Nerve conduction studies and electromyography confirm the presence of denervation and help exclude other potential causes of weakness.
- A sleep study should be strongly considered to evaluate for the presence of sleep-disordered breathing.
- Pulmonary function tests should be strongly considered to evaluate for evidence of respiratory weakness.
- A swallow study should be performed in patients with difficulty swallowing.

LABORATORY TESTS

Complete blood count, electrolytes, and thyroid function tests are conducted to exclude other causes of fatigue. Erythrocyte sedimentation rate is typically normal, and an increase in creatine kinase levels (if any) is nonspecific.

IMAGING STUDIES

Magnetic resonance imaging of the brain and spine can be helpful in excluding other potential causes of weakness.

CRITERIA FOR DIAGNOSING POSTPOLIOMYELITIS SYNDROME

- Prior episode of poliomyelitis with evidence of residual lower motor neuron loss
- Duration of acute onset of polio and neurologic and functional stability of 15 or more yr
- Gradual onset of persistent new weakness and abnormal muscle fatigability (lasting 1 yr or longer)
- Exclusion of other conditions mentioned in the previous differential diagnosis section

TREATMENT

There is no specific therapy for PPS. However, a multidisciplinary management program tailored to the patient's presentation can be very helpful in the management of symptoms, resulting in improved functionality and quality of life.
- Most individuals will benefit from physical activity regimens (i.e., nonfatiguing exercise programs) designed by a physical therapist to focus on energy conservation and pacing.
- Orthoses and assistive devices may facilitate ambulation and other activities of daily living as well as reduce the risk of falls.
- Pain can often be controlled with conservative measures such as activity and lifestyle modifications, but analgesic medications may be necessary in some cases. Amitriptyline has been found to help with relief of pain and fatigue in anecdotal cases.
- Trials indicate that drugs such as intravenous immune globulin (IVIG) and lamotrigine as well as application of static magnetic fields over identified trigger points may be beneficial in treating muscle weakness and pain, but results have been conflicting and routine clinical use is not recommended.
- Several studies evaluating the use of pyridostigmine for the treatment of weakness and fatigue in PPS have had conflicting results.
- Studies evaluating amantadine, modafinil, prednisone, and human growth hormone have failed to show any definitive benefit.

DISPOSITION

- The symptoms of PPS tend to be slowly progressive and may stabilize over the course of years.
- The weakness, fatigue, and pain may result in disability.
- Rarely fatal, but individuals with respiratory weakness and dysphagia are at increased risk and may benefit from early use of noninvasive respiratory support.

REFERRAL

- Neuromuscular specialist can assist in diagnosis and management.
- Physiatry, physical therapy, and occupational therapy for rehabilitation and assistive devices.
- Speech therapy referral is useful in patients with dysarthria or dysphagia.
- Pulmonary consult should be obtained for patients with symptoms or signs of respiratory weakness.
- Orthopedic consult may be necessary for patients requiring surgical correction of joint deformities.

- A mental health professional can assist with management of depression and other psychosocial issues.

PEARLS & CONSIDERATIONS

COMMENTS

- A diagnosis of PPS should only be made after a thorough evaluation for other potential causes of the patient's symptoms has been completed.
- Due to the high incidence of PPS among the large number of poliomyelitis survivors, PPS is the most common motor neuron disease worldwide.
- For patients with PPS who need to undergo surgical procedures, shorter-acting anesthetic agents should be used due to these patients' impaired baseline respiratory status and their potentially increased sensitivity to anesthetic and nondepolarizing neuromuscular blocking agents.

Poliomyelitis (Related Key Topic)

AUTHOR: **Divya Singhal, MD**

Postthrombotic Syndrome

BASIC INFORMATION

DEFINITION

Postthrombotic syndrome (PTS) is a delayed complication of deep vein thrombosis (DVT) that leads to signs and symptoms of venous insufficiency.

SYNONYMS

Postphlebitic syndrome
Chronic venous insufficiency
PTS

ICD-10CM CODES

I87.001	Postthrombotic syndrome without complications of right lower extremity
I87.002	Postthrombotic syndrome without complications of left lower extremity
I87.003	Postthrombotic syndrome without complications of bilateral lower extremities

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 23% to 60% of people with DVT will experience postthrombotic syndrome, often within 2 yr of onset of DVT.
PREVALENCE: Unknown
PREDOMINANT SEX: Slightly female predominance
RISK FACTORS: Symptomatic DVT, postoperative DVT, recurrent DVT, underlying primary venous insufficiency, younger age, obesity, presence of varicose veins, proximal DVT, residual thrombus after 6 months of treatment, and inadequate antithrombotic treatment

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms can be intermittent or constant and often appear weeks to months following DVT, but can occur up to years later. Symptoms are generally progressive over time and include pain in the extremity, heaviness of effected limb, itching, cramps, and paresthesia. Physical signs include edema of extremity, changes in skin pigmentation, venous dilation, telangiectasia, and ulceration (Fig. E1).

ETIOLOGY

Venous insufficiency results from chronic venous hypertension due to obstruction from thrombus and to reflux related to valvular incompetence. Inflammatory cytokines such as interleukin-6 are thought to play a role.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

DVT, primary venous insufficiency, Baker cyst, tumor, lymphedema, lipedema, and injury to extremity.

WORKUP

Clinical diagnosis based on history of DVT and signs and symptoms of chronic venous insufficiency. The Villalta scale can be used in cases when the diagnosis is uncertain. It is the most widely used scoring system for both diagnosing postthrombotic syndrome (PTS) and assessing its severity.

- Entails five patient symptoms (pain, leg cramps, heaviness in extremity, paresthesia, and pruritus) and six physical signs (pretibial edema, skin induration, hyperpigmentation, pain with calf compression, venous ectasia, and redness).
- Scored on a scale of 0 to 3 (0 = none, 1 = mild, 2 = moderate, 3 = severe).
- Total score ranges from 0 to 33; a score ≥5 is consistent with a diagnosis of PTS.
  1. PTS can also be diagnosed if a venous ulcer is present independent of total score.
- Severity is assessed based on score:
  1. Mild = score of 5 to 9
  2. Moderate = score of 10 to 14
  3. Severe = score of 15 to 33

LABORATORY TESTS

None presently used

IMAGING TESTS

Venous duplex ultrasonography or compression ultrasonography can be done to look for prior evidence of DVT but is not necessary to make the diagnosis.

TREATMENT

- First-line treatment includes compression stockings, regular exercise, and elevation of extremity.
- Lymphedema therapy and intermittent pneumatic compression devices can be used as well.
- Skin care is important, particularly in cases with eczematous changes. Moisturizing lotions can be used in conjunction with mild potency corticosteroids.
- Diuretics have a limited role but can decrease edema in some patients.
- Endovascular recanalization can be considered for cases that are refractory to treatment and where pain control is difficult. Two randomized controlled trials have been done to study the benefits.
- A 2007 randomized controlled trial, Catheter Directed Venous Thrombolysis in Acute Iliofemoral Vein Thrombosis, sought to answer the question of whether early endovascular recanalization would reduce long-term venous disease or improve quality of life. After 2 yr of follow up, there was no significant difference between groups with respect to either primary end point.
- A second trial, Acute Venous Thrombosis: Thrombus Removal with Adjunctive Catheter-Directed Thrombolysis (ATTRACT), was a randomized multicenter trial conducted to assess whether catheter-directed thrombolysis (CDT) along with a device that aspirates and breaks down thrombus was superior to standard therapy at preventing postthrombotic syndrome. However, no significant difference was found between groups (47% in the treatment group vs 48% in the control group developed PTS; risk ratio, 0.96; 95% confidence interval, 0.82 to 1.1; P=0.56).
- The American College of Cardiology does not recommend routine use of CDT as first-line treatment but states it may be useful for patients at low risk of bleeding or for those with limb-threatening complications.
- Surgical repair is generally reserved for severe cases causing acute limb-threatening circulatory compromise and for those with nonhealing ulcers. Surgical options include angioplasty, venous bypass, or endophlebectomy.

DISPOSITION

- Chronic venous insufficiency can impair quality of life and is often a chronic condition.
- Early treatment with anticoagulation may decrease the risk of postthrombotic syndrome.
- Early use of compression stockings can reduce symptoms of venous insufficiency and halt progression.

REFERRAL

Lymphedema clinic, interventional radiology, and vascular surgery

PEARLS & CONSIDERATIONS

COMMENTS

Compression stockings have the most evidence both for preventing postthrombotic syndrome and for treatment once the syndrome has developed.

PREVENTION

There is evidence both for and against early treatment with thrombolytic drugs to prevent postthrombotic syndrome. Reducing the recurrence of DVT is the best way to prevent PTS. With each subsequent DVT the risk of PTS increases. Periodic leg elevation, weight loss, smoking cessation, and regular exercise are all thought to prevent PTS; however, no randomized controlled trial has been done to evaluate.

BASIC INFORMATION

DEFINITION

Posttraumatic stress disorder (PTSD) develops in some people after witnessing or experiencing a traumatic event that involves actual or threatened injury to self or others. Symptoms continue longer than a mo after the event or may have delayed onset and include intrusive thoughts, nightmares, flashbacks, avoidance of things associated with the trauma, hypervigilance, sleep disturbance, and negative changes in mood and cognition. These symptoms cause distress and a decline in interpersonal, social, and occupational functioning. People with PTSD may feel numb or irritable, may be easily startled or frightened, and sometimes isolate themselves from others. They are at risk for comorbid psychiatric illness, substance abuse, and suicide.

SYNONYMS

PTSD
Soldier's heart
Effort syndrome
Shell shock
Concentration camp syndrome

ICD-10CM CODES	
F43.10	Post-traumatic stress disorder, unspecified
F43.11	Post-traumatic stress disorder, acute
F43.12	Post-traumatic stress disorder, chronic
DSM-5 CODES	
309.81	Posttraumatic stress disorder
309.89	Other specified trauma and related disorder
309.9	Unspecified trauma and stressor-related disorder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Fewer than 10% of individuals who have experienced a traumatic event will develop PTSD; however, there is considerable variability in prevalence rates associated with specific trauma types.

PREVALENCE (IN U.S.):

- 12-mo prevalence in the U.S. 3% to 6%. Estimated lifetime prevalence 7.8% to 12.3%.
- Prevalence among high-risk populations (e.g., combat veterans or victims of violent crimes) up to 58%.
- Comorbidity is common: depression, anxiety, substance use, personality disorders, and somatic symptom disorder.
- Factors most associated with development are previous traumatic experience and subsequent life stress and perceived lack of social support.

PREDOMINANT AGE AND SEX:

- No predisposing age factors.
- Twice as many women as men are affected (prevalence 10% to 14% for women and 5% to 6% for men). More than 50% of cases in women are related to sexual assault.

GENETICS: Several studies, including twin studies, have demonstrated genetic factors associated with increased risk of developing PTSD after trauma exposure.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Core symptom clusters include intrusion, avoidance, negative mood and cognition, hyperarousal, and sometimes dissociative symptoms. Individuals present with different variations of these symptoms.. Individuals who display these core symptom clusters within the first posttrauma mo are said to have acute stress disorder. In PTSD, these symptoms must be present >1 mo after the trauma and result in significant distress and functional impairment.

Key PTSD symptoms:

- Distressing memories or dreams of the event. NOTE: Children older than 6 yr may express this symptom in repetitive play
- Flashbacks
- Intense distress after reminders of the event
- Avoidance due to trauma-related thoughts or feelings
- Persistent negative trauma-related emotions
- Feeling detached
- Aggressive or reckless behavior
- Hypervigilance
- Problems with concentration or sleep
- Depersonalization

ETIOLOGY

- Common types of trauma: Violent personal assault, natural disaster, military combat, rape, motor vehicle accident, childhood abuse and neglect, critical illness or hospitalization in ICU, severe physical injury, diagnosis of life-threatening illness.
- Risk factors: Previous trauma, initial severity of reaction to event, psychiatric history, traumatic brain injury, childhood abuse or neglect, poor social support, gender, age.
- Interpersonal violence is more likely to cause PTSD than events such as motor vehicle accidents or natural disasters.
- Severity of physical injury is a weaker predictor of PTSD than the psychological distress; stress duration and social support are factors, among others.
- Proposed mechanisms include activation of the amygdala, disruption of prefrontal cortex modulation of the amygdala, and excessive stress-induced HPA and alpha-1 receptor activation.

DIAGNOSIS

Diagnosis is made when the stressor is consistent with DSM-5 definition, with symptoms of reexperiencing, avoidance, negative mood and cognition, and arousal and reactivity. The symptoms must be present for >1 mo, must cause impairment in functioning, and must not be attributable to substance use or other medical conditions. Subtypes include dissociative (PTSD criteria and depersonalization or derealization) and delayed onset (PTSD criteria starting at least 6 mo after the event).

Definition of stressor:

- Exposure to death, threatened death, actual or threatened serious injury, or actual or threatened sexual violence with directly experiencing the event, witnessing the event occur to others, or learning that a close relative or close friend was exposed to trauma. If the event involved actual or threatened death, it must have been violent or accidental.
- Repeated or extreme indirect exposure to aversive details of the event(s), usually in the course of professional duties (e.g., first responders collecting body parts; professionals repeatedly exposed to details of child abuse).

DIFFERENTIAL DIAGNOSIS

- Adjustment disorders: Precipitating stress is less catastrophic and psychological reaction is less specific
- Mood disorder: Depression or bipolar
- Anxiety disorders
- Somatic symptom or conversion disorder (functional neurological symptom disorder)
- Psychotic disorder
- Traumatic brain injury

WORKUP

- Validated self-report questionnaires and structured diagnostic instruments include the Posttraumatic Diagnostic Scale and Clinician Administered PTSD Scale (CAPS).
- Although numerous potential biomarkers have been identified and are under investigation, at this time evidence is not conclusive. To date, laboratory and imaging are not clinically useful.
- Primary care PTSD (PC-PTSD) screen recommended by the Veterans' Administration.
- "Yes" answer to three of four of the following questions is a positive screen. In your life, have you ever had any experience that was so frightening, horrible, or upsetting that, in the past mo, you:
  1. Have had nightmares about it or thought about it when you did not want to?
  2. Tried hard not to think about it or went out of your way to avoid situations that reminded you of it?
  3. Were constantly on guard, watchful, or easily startled?
  4. Felt numb or detached from others, activities, or your surroundings?

TREATMENT

- According to the most recent International Society for the Study of Traumatic Stress (ISTSS) treatment guidelines, cognitive-behavioral therapy approaches, including prolonged exposure (PE) and cognitive processing therapy (CPT), have the greatest empirical support to date among psychotherapy approaches.
- Prolonged exposure (PE) includes psychoeducation on the stress response, imaginal exposure focused on recounting trauma memories, and in vivo exposure focusing on reducing avoidance of anxiety-provoking situations associated with the trauma.

- CPT includes written exposure to the trauma memory combined with cognitive therapy.
- A recent clinical trial found that brief written exposure therapy intervention was noninferior to standard CPT and had fewer dropouts.
- Group therapy. Current standards recommend individual therapy as first-line. A growing number of studies have demonstrated efficacy of cognitive behavioral therapy (CBT) in a group format, although results are mixed, with some studies finding individual therapy to be superior.
- Eye movement desensitization reprocessing (EMDR) is considered an evidence-based treatment for PTSD in treatment guidelines, demonstrating comparable efficacy to traditional CBT approaches in clinical trials. However, to date it is unclear whether it offers advantages over, or operates through distinct mechanisms from, traditional CBT approaches. Evidence supporting the efficacy of the eye movements and parallel stimulation component is limited.
- A growing number of studies have demonstrated efficacy of CBT approaches for PTSD delivered through novel formats, including exposure therapy integrating virtual reality technology and Internet- and telephone-delivered CBT, although more research is needed to ascertain whether these approaches are comparable to traditional formats.
- Couples therapy when appropriate.

MEDICATIONS

There is no definitive cure for PTSD, and individuals have varying responses to different medications. Sertraline and paroxetine, both SSRIs, are the only FDA-approved medications for PTSD. Other medication use is off-label with differing levels of evidence to support use. Medications are used to target symptoms and the physiologic changes associated with PTSD and with psychiatric disorders that are frequently comorbid with PTSD. According to ISTSS treatment guidelines, SSRIs and SNRIs are currently considered the first-line pharmacologic treatments for PTSD, and it is recommended that they be prescribed for duration of at least 8 to 12 wk, with some studies demonstrating maximum benefit reached as late as 36 wk.

- SSRIs: Sertraline, paroxetine, fluoxetine.
- SNRIs: Venlafaxine, duloxetine.
- Other antidepressants: Mirtazapine has shown efficacy in small randomized trials.
- Alpha-adrenergic receptor blockers: Prazosin has demonstrated some efficacy in reducing nightmares. A meta-analysis of six RCTs comparing prazosin to placebo found a significant reduction in distress and/or frequency of nightmares, but a recent RCT in military veterans with PTSD did not show efficacy.
- Atypical antipsychotics (e.g., risperidone, quetiapine, olanzapine) have demonstrated efficacy as augmenting agents for individuals with partial response to SSRIs and may be particularly beneficial for individuals with paranoia, extreme anxiety, or angry outbursts.
- Transcranial magnetic stimulation (TMS) is being evaluated as a possible effective treatment modality.
- Ketamine: Recent clinical trials of intravenous ketamine infusion showed PTSD and depression symptom reduction, although more research is needed.
- *N*-methyl-D-aspartate (NMDA) agonists and partial agonists have shown some efficacy in early clinical trials, although more research is needed.
- Recent efforts are underway to examine the efficacy of pharmacologic interventions in preventing development of PTSD early after exposure to trauma, though more research is needed.

ACUTE GENERAL Rx

- Immediate post-incident debriefing may worsen outcome.
- Benzodiazepines are not currently recommended as monotherapy for the treatment of PTSD, as there is no evidence that they reduce reexperiencing and avoidance/numbing symptoms.
- Betaadrenergic blockers may be helpful if given within hours after the trauma to disrupt the physiologic stress response, although more research is needed.
- Sedating antidepressants or sleep aids may be helpful for initial insomnia.

DISPOSITION

- Recovery rates are highest in the first 12 mo after onset.
- Average duration of symptoms is 36 mo for those who undergo treatment and 64 mo for those never treated.
- 50% chance of remission at 2 yr; 50% have chronic symptoms.
- Predictors of chronic course include previous trauma, premorbid psychiatric function, panic reaction at time of event, prolonged terror, or dissociation at time of event.

REFERRAL

Because early intervention improves outcome, refer to a specialist as soon as diagnosis made.

PEARLS & CONSIDERATIONS

- PTSD is associated with increased occurrence of suicidal ideation and attempts.
- PTSD can be associated with aggressive and violent behavior.
- Traumatic medical experiences such as being in the ICU, myocardial infarction, or an emergent cesarean section can cause PTSD.
- Individuals with PTSD frequently present with comorbid psychiatric disorders, including substance abuse, major depression, anxiety disorders, and personality disorders.
- Among combat veterans of recent wars, there is a 41% cooccurrence with mild TBI.
- PTSD may vary culturally and present as culturally specific syndromes and idioms of distress.
- Treatment can be effective even if it begins yrs after the traumatic event occurred.
- Cannabis is available from medical dispensaries in many states for treating PTSD, yet its efficacy in treating PTSD symptoms remains uncertain. Current evidence is insufficient to draw conclusions about the benefits and harms of plant-based cannabis preparations in patients with PTSD, but several ongoing studies may soon provide answers.[1]

Postural Orthostatic Tachycardia Syndrome (POTS)

BASIC INFORMATION

DEFINITION

Postural orthostatic tachycardia syndrome (POTS) is an under-recognized autonomic disorder defined as a form of orthostatic intolerance in which an exaggerated increase in heart rate (HR >30 beats per min from baseline, or an increase to 120 beats per min within the first 10 min of standing or tilt table testing) occurs during postural change, without orthostatic hypotension. Symptoms occur while standing and are relieved by recumbency. The orthostatic intolerance should be chronic, lasting for at least 3 to 6 months. Symptoms may be profoundly exacerbated by simple activities, dehydration, or even eating; thus, POTS can be very disabling.

SYNONYMS

Orthostatic tachycardia
Orthostatic intolerance
POTS
Postural tachycardia syndrome
Chronic orthostatic intolerance
Neurocirculatory asthenia

ICD-10CM CODE

I49.8 Disorder of the autonomic nervous system, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown

PREVALENCE: Most prevalent form of orthostatic intolerance—estimated to be 5 to 10 times more common than orthostatic hypotension; ~3,000,000 patients in the United States (25% are disabled and unable to work)

PREDOMINANT SEX AND AGE: Female:male ratio of 5:1. Mean age is 30 yr old (most commonly between 15 to 50 yr old).

GENETICS: POTS is a heterogeneous entity, and thus, no single mutation is responsible for the syndrome. Mutations in a norepinephrine transporter have been identified in one case of familial POTS. They result in decreased norepinephrine clearance at the synaptic cleft, causing excessive sympathetic activation. Additionally, polymorphisms in genes encoding the beta-2 adrenoreceptor and nitric oxide synthase may also play a role in some patients.

RISK FACTORS:

- Female sex
- Family history
- Preceding viral infection or systemic illness (up to 50% of cases)
- Deconditioning and prolonged bed rest
- Medications (e.g., vasodilators, diuretics, antidepressants, anxiolytic agents)
- Predisposition to hypovolemia
- Autoimmune disorders (e.g., multiple sclerosis, mast cell activation syndrome)
- Excessive sympathetic states (e.g., sepsis, trauma, surgery)
- Underlying autonomic neuropathy such as in advanced diabetic states
- Chronic fatigue syndrome (40% have POTS)
- Mitral valve prolapse
- Joint hypermobility disorders (e.g., Ehlers-Danlos syndrome)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms vary and may be related to orthostasis (with cerebral hypoperfusion) or autonomic dysfunction. In some patients, symptoms manifest as non-orthostatic, generalized complaints. Common symptoms on presentation include:

- Palpitations, particularly with standing
- Anxiety, depression, or memory problems
- Tremulousness
- Dizziness, lightheadedness, blurred vision, presyncope, and syncope
- Intolerance to exercise or heat and constantly feeling cold
- Nausea, abdominal pain, and irritable bowel syndrome
- "Coat-hanger" headaches involving the upper trapezius muscle
- Cyclic nature (e.g., worsening with intravascular volume changes during menstrual cycle)
- Chronic fatigue and daytime sleepiness

Physical findings are key in raising clinical suspicion for POTS. Important physical findings include the orthostatic hemodynamic changes and a reduced pulse pressure with marked beat-to-beat variability of both pulse pressure and HR. Flack sign is the difficulty in palpating a radial pulse with continued standing or Valsalva maneuver. There may be venous prominence with continued standing resulting in acrocyanosis and swelling of the feet.

- 10% of dysautonomic POTS may progress to paroxysmal atrial fibrillation.
- Recent studies suggest a link between dysautonomia, POTS, and joint hypermobility syndrome.

ETIOLOGY

Heterogenous etiologies, which overlap in different types of POTS:

- Hypovolemic POTS: Decreased effective intravascular volume with peripheral and splanchnic venous pooling that worsens with standing. Studies have demonstrated a reduced plasma volume and red blood cell count in patients with POTS. These patients were also noted to have low renin and aldosterone levels despite their hypovolemic states, which suggests a renal involvement in the pathophysiology of POTS.
- Neuropathic or dysautonomic POTS: Patchy sympathetic denervation of lower extremities and kidneys resulting in orthostatic venous pooling and relative hypovolemia with failure of the peripheral vasculature to vasoconstrict properly upon standing.
- Hyperadrenergic or beta hypersensitivity POTS: High orthostatic plasma norepinephrine levels (≥600 pg/ml); prominent symptoms are of sympathetic over-activation. Patients may have significant orthostatic hypertension. An underlying genetic disorder may be a possible cause.
- Deconditioned POTS: Venous pooling in lower extremities due to weak leg "muscle pump"; fibromyalgia-type symptoms with anxiety, exercise intolerance, and fatigue.
- Immune-related POTS: Classically associated with mast cell activation syndrome (MCAS), though can occur in the setting of other autoimmune disorders. Patients will complain of episodic flushing with tachycardia. Hypertension with orthostatic tachycardia is common.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Orthostatic hypotension
- Inappropriate sinus tachycardia

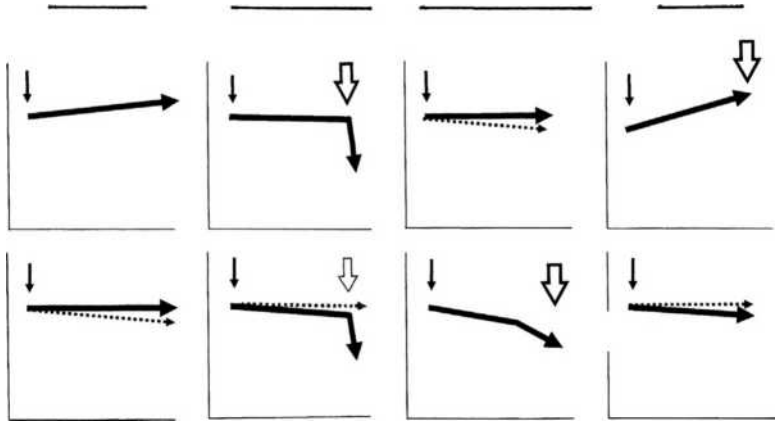

FIG. E1 Schematic drawing of changes in heart rate (HR) and blood pressure (BP) observed during the head-up tilt test. Thin arrows mark the start of orthostatic stress. Large unfilled arrows indicate the appearance of symptoms with changes seen in HR and BP. In normal individuals, the HR increases slightly with no change or a slight reduction in BP. In patients with vasovagal syncope, both the HR and BP drop precipitously with the appearance of symptoms. Postural hypotension is characterized by a drop in BP by 10 to 15 mm Hg as symptoms appear within 10 minutes of standing. Postural hypotension may not occur in the presence of good hydration. In POTS, the HR increases significantly by more than 30 beats/min (or the HR is 120 beats/min or higher) with development of symptoms within 10 minutes of standing. *POTS,* Postural orthostatic tachycardia syndrome. (Park MK: *Park's pediatric cardiology for practitioners,* ed 6, Philadelphia, 2014, WB Saunders.)

BOX E1 Pharmacologic Management of POTS

I β-adrenergic antagonists
- Atenolol 1-2 mg/kg per day
- Metoprolol 1-2 mg/kg per day
- Propranolol 0.5-4 mg/kg per day
- Nadolol

II α-adrenergic agonists
- Midodrine 2.5-10 mg tid
- Pseudoephedrine 60 mg bid
- Methylphenidate 5-10 mg tid

III Mineralocorticoids
- Fludrocortisone 0.1-0.3 mg/day

IV Pyridostigmine 30 mg bid

V Selective serotonin receptor reuptake inhibitors
- Fluoxetine 10-20 mg/day
- Sertraline 25-50 mg/day

POTS, Postural orthostatic tachycardia syndrome. From Swaiman KF et al: *Swaiman's pediatric neurology, principles and practice,* ed 6, Philadelphia, 2017, Elsevier.

- Dehydration or anemia
- Medication side effects
- Other forms of autonomic neuropathies
- Other forms of central dysautonomia
- Deconditioning
- Anxiety and panic attacks
- Vasovagal syncope
- Structural cardiac abnormalities (heart failure, valvulopathy, congenital heart disease)

WORKUP

- Full autonomic system review to evaluate for autonomic neuropathies
- Orthostatic vital signs
- 12-lead electrocardiogram
- Holter monitor in patients with syncope to rule out malignant tachyarrhythmias
- Head-up tilt table testing is diagnostic (Fig. E1). It should be considered in patients where clinical suspicion is high, but HR criteria have not been met after 10 min of standing. To improve diagnostic sensitivity, testing should take place in the morning. Findings during head-up tilt include:
  1. Increase in HR of ≥30 beats/min from baseline, or ≥120 beats/min within 10 min
  2. Absence of hypotension
  3. Orthostatic intolerance symptoms (see earlier)
  4. In select patients, plasma catecholamines can be measured during tilt-table, first while supine and again after standing for 15 min. In 50% of patients who are standing, norepinephrine level ≥600 pg/ml is found, signifying a hyperadrenergic response

LABORATORY TESTS

- Iron studies and complete blood count to evaluate for anemia
- Thyroid stimulating hormone to evaluate for thyroid disease
- 24-hr urine sodium; a level <100 mEq/L suggests a hypovolemic state
- Plasma and urine catecholamines in select patients to rule out pheochromocytoma in appropriate patients

IMAGING STUDIES

Transthoracic echocardiogram to rule out any underlying structural heart disease

Rx TREATMENT

Education about the pathophysiology of POTS and aggravating and alleviating factors can help patients better handle the condition. Suspected medications should be discontinued. ~40% to 90% of patients respond to a combination of non-pharmacotherapy and pharmacotherapy (Box E1). Nonpharmacologic therapies should be implemented first, with pharmacologic therapy reserved for patients with refractory symptoms. Additionally, proper management of underlying medical conditions that may be associated with the disorder can improve quality of life.

NONPHARMACOLOGIC THERAPY

Cornerstone of therapy is increasing vascular tone and effective intravascular volume with prevention of venous pooling. Treatment should take a graded approach, beginning with increasing water and salt intake, exercise and compression stockings.

- Aggravating factors such as alcohol intake, excessive caffeine, dehydration, and extreme heat should be avoided.
- Some measures, such as contracting muscles below the waist for 30 seconds and wearing abdominal binders or support hose, can reduce venous capacitance and increase total peripheral resistance.
- Drinking two 8-oz glasses of water sequentially can result in sympathetically mediated pressor response lasting for 1 to 2 hr.
- Patients, especially those with hypovolemic POTS, usually improve with increasing fluid (2 to 3 L/day) and sodium intake (10 to 20 g of salt). This should be avoided in patients with hyperadrenergic POTS.
- All patients (especially deconditioned ones) can benefit from an exercise-training program (aerobic with lower-extremity strengthening). Patients should work toward 20 to 30 min of aerobic exercise, three times weekly. Supine exercise, such as rowing and recumbent cycling, can be particularly beneficial. Regular supine exercise has been shown to improve symptoms to the point of remission in >70% of patients with POTS.
- Atrioventricular node ablation and pacemaker implantation can be considered for recurrent syncope refractory to all other therapies.

ACUTE GENERAL Rx

- Volume expansion with 1 L of normal saline over 1 to 3 hours
- Discontinuation of exacerbating factors

CHRONIC Rx

Appropriate pharmacologic treatment of POTS is dependent on the subtype. Treatments that are beneficial for one subtype may worsen other subtypes.

- Volume expanders such as fludrocortisone or desmopressin (DDAVP) can be useful for hypovolemic and neuropathic POTS.
- β-blockers (propranolol and atenolol) for neuropathic (allow for unopposed α-receptor-mediated vasoconstriction) and hyperadrenergic (block β1 receptors in heart) POTS. They may worsen symptoms in hypovolemic POTS by decreasing cardiac output.
- Ivabradine, which decreases HR but does not affect BP, improved symptoms in 60% of patients in one study. Especially helpful in hyperadrenergic POTS.
- SSRIs for neuropathic and hyperadrenergic POTS (decrease the central production of serotonin).
- Vasoconstrictors such as midodrine may be helpful for neuropathic POTS. Droxidopa should only be considered in refractory cases.
- Central sympatholytic agents (clonidine and methyldopa) for hyperadrenergic POTS.
- Erythropoietin for refractory neuropathic or hypovolemic POTS (increases sensitivity to angiotensin II).
- Pyridostigmine reduces tachycardia and may be an effective agent.
- Immunomodulatory agents such as IVIG and rituximab are being studied in the treatment of POTS to target immune dysautonomia but as of now are purely investigational.

DISPOSITION

Can usually be managed in an outpatient setting

REFERRAL

Cardiology and occasionally expertise in electrophysiology as needed

PEARLS & CONSIDERATIONS

COMMENTS

This syndrome remains poorly understood, and current therapies may not be effective. Because of its debilitating nature, young age of presentation, and recurrent symptoms, patients often feel discouraged and may need psychological support.

PREVENTION

None except therapies previously mentioned

BASIC INFORMATION

DEFINITION

Precocious puberty is defined as the development of secondary sexual characteristics before age 8 in females and age 9 in males.

SYNONYM

Pubertas praecox

ICD-10CM CODE
E30.1 Precocious puberty

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Estimated to be between 1 in 5000 to 1 in 10,000
PREDOMINANT SEX: Females are affected five times more often than males for the idiopathic variant; for other causes, it is dependent on the underlying etiology.
GENETICS: The genetics for some of the etiologies of precocious puberty is known. The most common genetic cause of central precocious puberty (CPP) in humans is a deficiency of *MKRN3* (makorin ring finger protein 3). Other reported genetic causes of CPP include a *MRF3* (MA3 domain-containing translation regulatory factor) loss of function mutation and a *KISS1* (KiSS-1 metastasis suppressor) gain of function mutation.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- In females: Breast development, pubic hair development, accelerated growth, menarche
- In males: Increase in testicular volume (>4 ml) and penile length, pubic hair development, accelerated growth, muscular development, acne, change in voice, penile erections

ETIOLOGY

- Central (Gonadotropin hormone-releasing hormone [GnRH]-dependent, "true precocious puberty"):
  1. Idiopathic (74%)—diagnosis of exclusion
  2. CNS problem (7%)
     a. Tumor, encephalitis, head trauma, hydrocephalus
- Peripheral (GnRH-independent, incomplete, pseudopuberty):
  1. Ovarian cyst or tumor (11%)
  2. McCune-Albright syndrome (5%)
  3. Adrenal feminizing or masculinizing (2%)
  4. Ectopic gonadotropin production (0.5%)
  5. Severe hypothyroidism (very rare)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Most common diagnoses to consider: Premature thelarche (breast tissue development in absence of other secondary sex characteristics or menarche) and premature adrenarche (axillary or pubic hair growth, acne, and/or body odor in absence of other secondary sex characteristics or menarche)
- Constitutional precocity—onset near 8 yr of age, familial
- GnRH-dependent precocious puberty: Idiopathic, CNS tumors, hypothalamic hamartomas, neurofibromatosis type I, tuberous sclerosis, hydrocephalus, status after acute head injury, ventricular cysts, status after CNS infection
- GnRH-independent precocious puberty: Congenital adrenal hyperplasia, adrenocortical tumors (males), McCune-Albright syndrome (females), gonadal tumors, ectopic human chorionic gonadotropin (hCG)-secreting tumors (chorioblastoma, hepatoblastoma), exposure to exogenous sex steroids, severe hypothyroidism
- Table E1 summarizes the differential diagnosis of sexual precocity

WORKUP

Priorities:
- Rule out life-threatening disease (neoplasm of central nervous system [CNS], gonad, adrenal). A classification of sexual precocity is summarized in Table E2.
- Establish velocity of process.
- A thorough history and physical examination are essential to determine if the patient has true precocious puberty. Particular attention should be paid to growth, development, order of appearance of the secondary sexual characteristics, pubertal development in family members, medications, neurologic symptoms, Tanner staging, abdominal and neurologic examination. Flowcharts for diagnosing sexual precocity in females and males are shown in Figs. 1 and 2.

LABORATORY TESTS

- GnRH stimulation testing will help determine if dependent or independent cause.
- Sex hormone studies: Luteinizing hormone, follicle-stimulating hormone, hCG, testosterone (males), estrogen (females). Levels of sex steroids should be determined in the morning, with use of assays that have detection limits adapted to pediatric values. In girls, serum estradiol levels are highly variable and have a rather low sensitivity for the diagnosis of precocious puberty.
- Free T_4, thyroid-stimulating hormone (TSH).

IMAGING STUDIES

- Bone age: Left hand/wrist x-ray establishes severity of process
- CT scan or MRI of the brain to evaluate for CNS pathology
- Consideration of pelvic ultrasound in female patients to evaluate for ovarian cysts or tumors
- Abdominal imaging with CT scan if intraabdominal pathology suspected

TREATMENT

NONPHARMACOLOGIC THERAPY

- Good communication with parents is essential to care.
- Psychological support for the child may be needed to address issues with self-image and peer acceptance.
- Given that sexual development occurs in advance of aging and maturity, social and emotional difficulties may occur. These children are also particularly vulnerable to sexual abuse.

ACUTE GENERAL Rx

There is no acute therapy for precocious puberty.

CHRONIC Rx

Therapy depends on the etiology of precocious puberty. For the treatment of central or gonadotropin-dependent precocious puberty depot GnRH agonists (leuprorelin, leuprolide, triptorelin, goserelin, histrelin, buserelin) are effective.
- Leuprolide is given 0.25 to 0.3 mg/kg with a 7.5 mg minimum IM every 4 wk. Local side effects include pain, erythema, and inflammatory reactions. Other side effects include headaches and menopausal-like symptoms (asthenia, hot flashes).
- For other CNS lesions and extragonadal tumors, therapy is dependent on the type of lesion, location of the lesion, and the overall prognosis of the underlying problem.
- For severe hypothyroidism, treatment with thyroid hormone will result in regression of the sexual development. The child will subsequently undergo appropriate pubertal development later in life.
- For familial male gonadotropin-independent precocious puberty, the androgen-synthesis inhibitor ketoconazole can be used at doses of 600 mg/day divided tid, or a combination of the aromatase inhibitors testolactone or anastrozole and spironolactone can be used.

DISPOSITION

- For true precocious puberty and some CNS lesions, long-term outcome is usually favorable. When pharmacological therapy is initiated, it is typically continued until the child is deemed to be of an appropriate age to progress through puberty.
- For other cases, long-term outcomes depend on the prognosis of the underlying cause.

REFERRAL

- Initial workup can be instituted by the primary care provider.
- Referral to an endocrinologist is indicated for most children for long-term management, monitoring, and treatment.
- Attention to the emotional well-being of the child is important.

Precocious Puberty (Patient Information)

AUTHORS: **Rachel Wright Heinle, MD FACOG,** and **Ashlie Sewdass Carter, MD**

TABLE E1 Differential Diagnosis of Sexual Precocity

Disorder	Plasma Gonadotropins	Lh Response to GnRH	Serum Sex Steroid Concentration	Gonadal Size	Miscellaneous
Gonadotropin Dependent					
True (central) precocious puberty	Prominent LH pulses (premature reactivation of GnRH pulse generator)	Pubertal LH response initially during sleep	Pubertal values of testosterone or estradiol	Normal pubertal testicular enlargement or ovarian and uterine enlargement	MRI of brain to rule out CNS tumor or other abnormality
Gonadotropin Independent					
Males					
Chorionic gonadotropin-secreting tumor in males	High hCG, low LH	Prepubertal LH response	Pubertal value of testosterone	Slight to moderate uniform enlargement of testes	Hepatomegaly suggests hepatoblastoma; MRI of brain if chorionic gonadotropin-secreting CNS tumor suspected
Leydig cell tumor in males	Suppressed	No LH response	High testosterone	Irregular, asymmetric enlargement of testes	
Familial, male-limited precocious puberty (FMPP, "testotoxicosis")	Suppressed	No LH response	Pubertal values of testosterone	Testes symmetric and >2.5 cm but smaller than expected for pubertal development; spermatogenesis occurs	Activating mutation of the LHCG receptor; autosomal dominant transmission
Virilizing congenital adrenal hyperplasia	Prepubertal	Prepubertal LH response	Elevated 17-OHP in CYP21 deficiency or elevated 11-deoxycortisol in CYP11B1 deficiency	Testes prepubertal	Autosomal recessive, variable severity/age of onset; may have salt loss in CYP21 deficiency or hypertension in CYP11B1 deficiency
Virilizing adrenal tumor	Prepubertal	Prepubertal LH response	High DHEAS, DHEA, and/or androstenedione values	Testes prepubertal	CT, MRI, or US of abdomen
Females					
Granulosa cell tumor (follicular cysts may present similarly)	Suppressed	Prepubertal LH response	Very high estradiol	Ovarian enlargement on physical examination, CT, MRI, or US	Tumor often palpable on physical examination
Follicular cyst	Suppressed	Prepubertal LH response	Prepubertal to very high estradiol	Ovarian enlargement on physical examination, CT, MRI, or US	Single or recurrent episodes of menses and/or breast development; exclude McCune-Albright syndrome
Feminizing adrenal tumor	Suppressed	Prepubertal LH response	High estradiol, variable DHEAS increase	Ovaries prepubertal	Unilateral adrenal mass
Nonclassical congenital adrenal hyperplasia	Prepubertal	Prepubertal LH response	Elevated 17-OHP in basal or corticotropin-stimulated state	Ovaries prepubertal	Autosomal recessive
In Both Sexes					
McCune-Albright syndrome	Suppressed	Suppressed	Sex steroid pubertal; estradiol may be quite high in girls	Ovarian enlargement (asymmetrical) on US; slight (usually symmetrical) testicular enlargement	Skeletal survey/bone scan for polyostotic fibrous dysplasia and skin examination for café au lait spots
Primary hypothyroidism	LH prepubertal; FSH may be slightly elevated	Prepubertal; FSH response flat	Estradiol may be pubertal	Testicular enlargement; ovaries cystic	TSH and prolactin elevated; T_4 low
Incomplete Precocity/Variations Of Puberty					
Premature thelarche	Prepubertal	Prepubertal LH	Prepubertal or early pubertal estradiol response	Ovaries prepubertal	Onset usually before 3 yr of age
Premature adrenarche (males)	Prepubertal	Prepubertal LH response	Prepubertal testosterone; DHEAS, or urinary 17-ketosteroid values appropriate for pubic hair stage 2	Testes prepubertal	Onset usually after 6 yr of age; more frequent in CNS-injured children
Premature adrenarche (females)	Prepubertal	Prepubertal LH response	Prepubertal estradiol; DHEAS or urinary 17-ketosteroid values appropriate for pubic hair stage 2	Ovaries prepubertal	Onset usually after 6 yr of age; more frequent in brain-injured children

CNS, Central nervous system; *CT,* computed tomography; *CYP,* P450 cytochrome isoenzyme; *DHEAS,* dehydroepiandrosterone sulfate; *FSH,* follicle-stimulating hormone; *GnRH,* gonadotropin-releasing hormone; *hCG,* human chorionic gonadotropin; *LH,* luteinizing hormone; *MRI,* magnetic resonance imaging; 17-*OHP,* 17-hydroxyprogesterone; T_4, thyroxine; *TSH,* thyrotropin; *US,* ultrasonography.

TABLE E2 Classification of Sexual Precocity

True Precocious Puberty Or Complete Isosexual Precocity (GnRH-Dependent Sexual Precocity Or Premature Activation Of The Hypothalamic GnRH Pulse Generator)

Idiopathic true precocious puberty
CNS tumors
Optic glioma associated with neurofibromatosis type 1
  Hypothalamic astrocytoma
Other CNS disorders:
  Developmental abnormalities including hypothalamic hamartoma of the tuber cinereum
  Encephalitis
  Static encephalopathy
  Brain abscess
  Sarcoid or tubercular granuloma
  Head trauma
  Hydrocephalus
  Arachnoid cyst
  Myelomeningocele
  Vascular lesion
  Cranial irradiation
True precocious puberty after late treatment of congenital virilizing adrenal hyperplasia or other previous chronic exposure to sex steroids
True precocious puberty due to mutations:
  in *KISS1R/GRP54* gene
  in *KISS1 gene*
  MKRN3 gene

Incomplete Isosexual Precocity (Hypothalamic GnRH-Independent)

Males

Gonadotropin-secreting tumors:
  hCG-secreting CNS tumors (e.g., chorioepitheliomas, germinoma, teratoma)
  hCG-secreting tumors located outside the CNS (hepatoma, teratoma, choriocarcinoma)
Increased androgen secretion by adrenal or testis:
  Congenital adrenal hyperplasia (CYP21 and CYP11B1 deficiencies)
  Virilizing adrenal neoplasm
  Leydig cell adenoma
  Familial testotoxicosis (sex-limited autosomal dominant pituitary gonadotropin-independent precocious Leydig cell and germ cell maturation)
    Cortisol resistance syndrome

Females

Ovarian cyst
Estrogen-secreting ovarian or adrenal neoplasm
Peutz-Jeghers syndrome with SCTAT

Both Sexes

McCune-Albright syndrome
Hypothyroidism
Iatrogenic or exogenous sexual precocity (including inadvertent exposure to estrogens in food, drugs, or cosmetics)

Variations Of Pubertal Development

Premature thelarche
Premature isolated menarche
Premature adrenarche
Adolescent gynecomastia in boys
Macroorchidism

Contrasexual Precocity

Feminization in Males

Adrenal neoplasm
Chorioepithelioma
CYP11B1 deficiency
Testicular neoplasm (Peutz-Jeghers syndrome)
Increased extraglandular conversion of circulating adrenal androgens to estrogen
Iatrogenic (exposure to estrogens)

Virilization in Females

Congenital adrenal hyperplasia:
  CYP21 deficiency
  CYP11B1 deficiency
  3β-HSD deficiency
Virilizing adrenal neoplasm (Cushing syndrome)
Virilizing ovarian neoplasm (e.g., arrhenoblastoma)
Iatrogenic (exposure to androgens)
Cortisol resistance syndrome
Aromatase deficiency

CNS, Central nervous system; *CYP11B1,* 11-hydroxylase; *CYP21,* 21-hydroxylase; *GnRH,* gonadotropin-releasing hormone; *hCG,* human chorionic gonadotropin; *3β-HSD,* 3β-hydroxysteroid dehydrogenase 4,5-isomerase; *KISS1R/GPR54,* kisspeptin/G protein–coupled receptor 54; *SCTAT,* sex cord tumor with annular tubules.

BASIC INFORMATION

DEFINITION

Preeclampsia involves the presence of hypertension with other associated comorbidities in a pregnant woman. In 2013, the American College of Obstetrics and Gynecology (ACOG) Task Force on Hypertension in Pregnancy revised the criteria, making preeclampsia a hypertensive disorder and one where the presence of proteinuria was no longer needed to make the diagnosis. The task force reinforced the importance of hypertension as a necessary condition and deemphasized proteinuria. In the absence of proteinuria, thrombocytopenia, new development of renal insufficiency, impaired liver function, pulmonary edema, and new-onset cerebral or visual symptoms could substitute as criteria.

Additionally, the task force emphasized the categories employed in prior ACOG bulletins:

- Preeclampsia: Hypertension with or without proteinuria, but with the presence of one of the previously mentioned comorbidities
- Preeclampsia with severe features (Table 1)
- Chronic hypertension: Hypertension predating pregnancy or present at <20 wk gestation
- Gestational hypertension: Hypertension in pregnancy after 20 wk without proteinuria or any of the previously mentioned comorbidities
- Chronic hypertension with superimposed preeclampsia: The presence of chronic hypertension with sudden increase in blood pressure or escalation of medication when previously well controlled or with development of new onset of signs or symptoms meeting criteria for severe preeclampsia. Table 1 summarizes the criteria for the diagnosis of severe preeclampsia
- Atypical preeclampsia: Onset prior to 20 wk; onset after 48 hr postpartum; gestational proteinuria with symptoms of preeclampsia, hemolysis, thrombocytopenia, or elevated liver enzymes

SYNONYMS

Pregnancy-induced hypertension
Toxemia of pregnancy

ICD-10CM CODES

011.1	Pre-existing hypertension with pre-eclampsia, first trimester
011.2	Pre-existing hypertension with pre-eclampsia, second trimester
011.3	Pre-existing hypertension with pre-eclampsia, third trimester
011.9	Pre-existing hypertension with pre-eclampsia, unspecified trimester
014.00	Mild to moderate pre-eclampsia, unspecified trimester
014.02	Mild to moderate pre-eclampsia, second trimester
014.03	Mild to moderate pre-eclampsia, third trimester
014.10	Severe pre-eclampsia, unspecified trimester
014.12	Severe pre-eclampsia, second trimester
014.13	Severe pre-eclampsia, third trimester
014.90	Unspecified pre-eclampsia, unspecified trimester
014.92	Unspecified pre-eclampsia, second trimester
014.93	Unspecified pre-eclampsia, third trimester

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 2% to 7% in primigravidas, up to more than 50% in multigravidas with risk factors
RISK FACTORS: See Table 2.
GENETICS: Positive correlation with maternal and paternal family history

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Preeclampsia typically presents with hypertension and proteinuria, most commonly in the third trimester of pregnancy.
- May be asymptomatic.
- Generalized swelling or nondependent edema, possibly manifested by rapid weight gain (>4 lb/wk), even in the absence of edema, is common but is nonspecific and is seen in many normal pregnancies.
- Auscultation of pulmonary rales.
- Cerebral symptoms: headache, vision changes
- Right upper quadrant pain (HELLP syndrome [hemolysis, elevated liver enzymes, and low platelet count] or subcapsular liver hematoma).
- Hyperreflexia or clonus.
- Vaginal bleeding (placental abruption).
- Chronic fetal compromise manifested by intrauterine growth restriction or acute fetal compromise manifested by nonreassuring fetal testing.
- Wide range of symptoms attributable to multiorgan system dysfunction, involving hepatic, hematologic, renal, pulmonary, and central nervous systems.
- Possibility of severe disease despite "normal" blood pressure readings, so a high index of suspicion must be maintained in high-risk situations.

ETIOLOGY

- Exact etiology is unknown.
- Theories:
  1. Imbalance between thromboxane A_2 (vasoconstrictor and platelet aggregator) and prostacyclin (vasodilator)
  2. Abnormal trophoblastic invasion of spiral arteries
  3. Increased sensitivity to angiotensin II by the muscular walls of the arteries
  4. Excess circulating soluble FMS-like tyrosine kinase 1 (*sFlt1*), which binds placental growth factor (PlGF) and vascular endothelial growth factor (VEGF), may have a pathogenic role
- Potential secondary effects of the metabolic, inflammatory endothelial alternatives in preeclampsia are described in Table 3.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute fatty liver of pregnancy
- Appendicitis
- Diabetic ketoacidosis
- Gallbladder disease
- Gastroenteritis
- Glomerulonephritis
- Hemolytic-uremic syndrome
- Hepatic encephalopathy
- Hyperemesis gravidarum
- Idiopathic thrombocytopenia
- Thrombotic thrombocytopenic purpura
- Nephrolithiasis
- Pyelonephritis
- Peptic ulcer disease
- Systemic lupus erythematosus

TABLE 1 Criteria for the Diagnosis of Preeclampsia with Severe Features

In patients with preeclampsia, **preeclampsia with severe features** can be diagnosed if any one of the following criteria is present:

Blood pressure ≥160 mm Hg systolic or ≥110 mm Hg diastolic on two separate occasions at least 4 hr apart

Serum creatinine >1.1 mg/dl or a doubling of the serum creatinine

New onset of cerebral or visual disturbances

Pulmonary edema

Hepatocellular injury (serum transaminases at least twice normal) or severe persistent right upper quadrant or epigastric pain

Thrombocytopenia <100,000

TABLE 2 Risk Factors for Preeclampsia

- Nulliparity
- Age >40 yr
- Pregnancy with assisted reproduction
- Interpregnancy interval >7 yr
- Family history of preeclampsia
- Woman born small for gestational age
- Obesity/gestational diabetes
- Multifetal gestation
- Preeclampsia in a previous pregnancy
- Poor outcome in a previous pregnancy
- Fetal growth restriction, placental abruption, fetal death
- Preexisting medical-genetic conditions
- Chronic hypertension
- Renal disease
- Type 1 (insulin-dependent) diabetes mellitus
- Antiphospholipid antibody syndrome

From Gabbe SG et al: *Obstetrics,* ed 7, 2016, Philadelphia, Elsevier.

- Viral hepatitis
- Medications or medication withdrawal

WORKUP

Hypertension:

- Two blood pressure measurements at least 4 hr apart, with the patient sitting or semi-reclining with the back supported, with an absolute pressure ≥140 mm Hg systolic or ≥90 mm Hg diastolic
- Blood pressure ≥160 mm Hg systolic or ≥110 mm Hg diastolic
- Hypertension can be confirmed in a brief period to allow for immediate treatment of severe range blood pressure.

Proteinuria:

- ≥300 mg per 24-hr urine collection
- Protein/creatinine ratio ≥0.3
- +1 on dipstick ONLY IF OTHER METHODS NOT AVAILABLE

TABLE 3 Potential Secondary Effects of the Metabolic, Inflammatory Endothelial Alternatives in Preeclampsia

CVS	Increased peripheral resistance leading to hypertension; increased vascular permeability and reduced maternal plasma volume.
Lungs	Laryngeal and pulmonary edema.
Renal	Glomerular damage leading to proteinuria, hypoproteinemia, and reduced oncotic pressure, which further exacerbates the hypovolemia. May develop acute renal failure ± cortical necrosis.
Clotting	Hypercoagulability, with increased fibrin formation and increased fibrinolysis (i.e., disseminated intravascular coagulation).
Liver	HELLP syndrome hepatic rupture.
CNS	Thrombosis and fibrinoid necrosis of the cerebral arterioles. Eclampsia (convulsions), cerebral hemorrhage, and cerebral edema.
Fetus	Impaired uteroplacental circulation, potentially leading to FGR, hypoxemia, and intrauterine death.

CVS, Cardiovascular system; *CNS,* central nervous system; *FGR,* fetal growth restriction; *HELLP,* hemolysis, elevated liver enzymes, low platelets.
From Drife J, Magowan B: *Clinical obstetrics and gynecology,* Philadelphia, 2004, WB Saunders.

- In the absence of proteinuria, preeclampsia may be diagnosed with new onset of hypertension and one of the following:
  1. Platelet count less than 100,000/ml
  2. New-onset, progressive renal insufficiency, serum creatinine concentrations greater than 1.1 mg/dl, or doubling of serum Cr levels in the absence of other renal disease
  3. Elevated serum liver transaminases to twice the normal concentration
  4. Pulmonary edema
  5. New-onset cerebral or visual symptoms
- Because of the insidious nature of the disease with potential for multiple organ involvement, as well as its prevalence, complete evaluation for preeclampsia in any pregnant patient presenting with central nervous system derangement or gastrointestinal symptoms after 20 wk of gestation
- Evaluation for associated conditions such as disseminated intravascular coagulation, hepatic dysfunction, or subcapsular hematoma
- Fig. 1 outlines a management plan for patients with severe preeclampsia

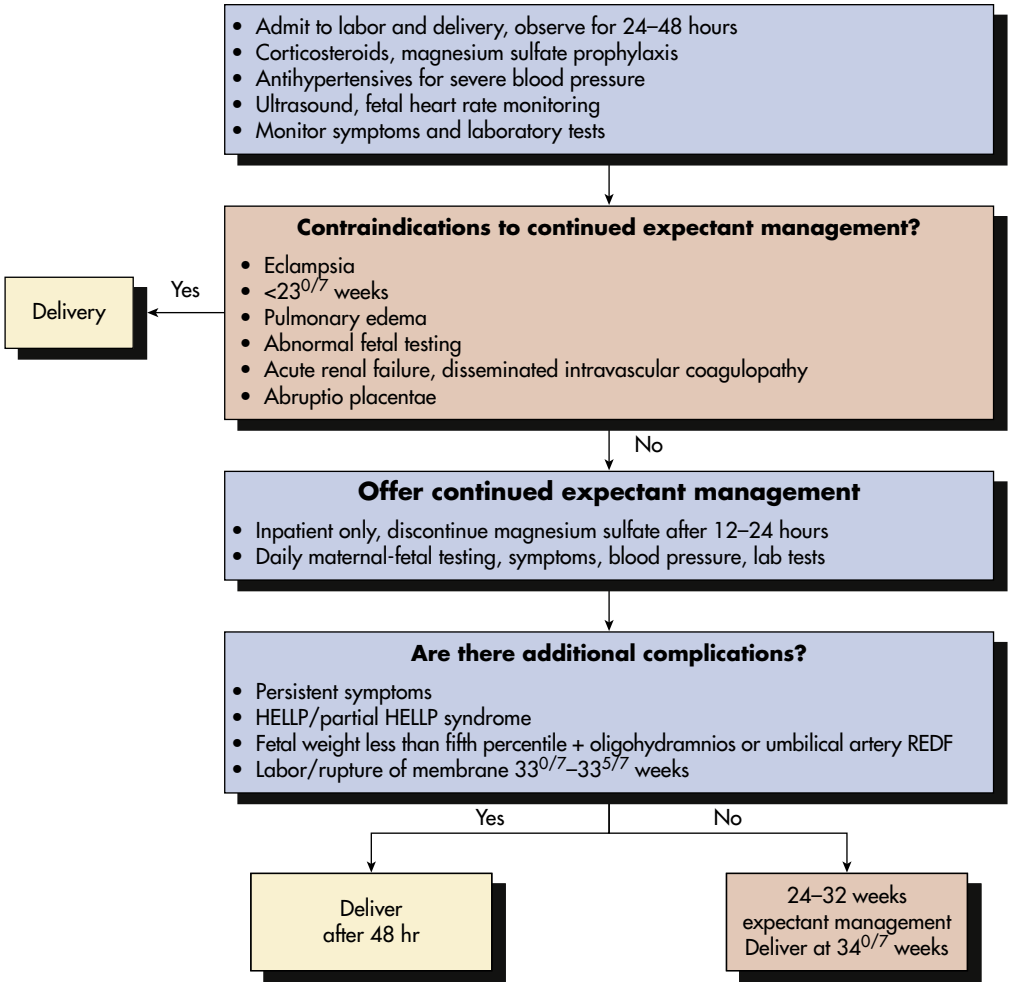

FIG. 1 Management plan for patients with preeclampsia with severe features before 34 wks' gestation. *HELLP,* hemolysis, elevated liver enzymes, and low platelets; *REDF,* reversed end-diastolic flow. (From Gabbe SG et al: *Obstetrics: Normal and problem pregnancies,* ed 7, Philadelphia, 2017, Elsevier.)

LABORATORY TESTS

- High-risk patients: Baseline assessment of renal function (24-hr urine collection for total protein and creatinine clearance or protein:creatinine ratio), complete blood count, serum creatinine, liver function tests (LFTs), and uric acid should be obtained at the first prenatal visit.
- Complete blood count (hemoglobin, hematocrit, platelets) may show signs of hemoconcentration or HELLP syndrome.
- LFTs (aspartate aminotransferase, alanine aminotransferase, lactate dehydrogenase) are useful in evaluation for HELLP syndrome or to exclude important differentials.
- Hyperuricemia or increased creatinine may indicate decreasing renal function.
- Prothrombin time, partial thromboplastin time, and fibrinogen can be checked to rule out disseminated intravascular coagulation, if clinically appropriate.
- Peripheral smear may demonstrate microangiopathic hemolytic anemia.
- Complement levels can be used to differentiate from an acute exacerbation of a collagen-vascular disease.
- The ratio of soluble FMS-like tyrosine kinase 1 (sFlt-1) to placental growth factor (PlGF) is elevated in pregnant women before the clinical onset of preeclampsia. Increased levels of sFlt1 and reduced levels of PlGF predict subsequent development of preeclampsia. An sFlt-1:PlGR ratio of 38 or lower can be used to predict the short-term absence of preeclampsia in women in whom the syndrome is suspected clinically.[1]

IMAGING STUDIES

- CT or MRI scan of head if atypical presentation of eclampsia or preeclampsia with atypical cerebral symptoms, possibility of intracerebral bleed, or prolonged postictal state
- Sonogram of fetus to evaluate for intrauterine growth restriction amniotic fluid, placenta
- Sonogram of maternal liver if subcapsular hematoma suspected

Rx TREATMENT

ACUTE GENERAL Rx

Delivery is the treatment of choice and the only cure for the disease. This must be taken in the context of the gestational age of the fetus, severity of the preeclampsia, and the likelihood of a successful induction and reliability of patient, if pursuing expectant management.

- For preeclampsia with severe features, administer magnesium sulfate 4 to 6 g IV loading dose, with 2 g/hr maintenance (adjust dosage for renal insufficiency). If there is a contraindication to magnesium sulfate, such as myasthenia gravis, then use phenytoin at 10 to 15 mg/kg loading dose, then 200 mg IV q8h starting 12 hr after loading dose.
- Treat blood pressure (BP) >160 mm Hg systolic or >110 mm Hg diastolic either with hydralazine 5 to 10 mg IV, then 10 mg, every 20 min to a max dose of 20 mg; or with labetalol hydrochloride 20, 40, 80, 80 mg IV, escalating dosage every 10 min to a max dose of 300 mg IV; or with nifedipine 10 to 20 mg orally every 20 min for acute blood pressure control, to a max dose of 180 mg/day. If maximum dose of one medication is reached, add an additional medication to reach goal of BP 140 to 150/90 to 100 mm Hg.
- Continuous fetal monitoring.
- Epidural is anesthesia of choice for pain management in labor or cesarean section.
- All patients undergoing induction of labor or cesarean section should receive antiseizure medications (magnesium sulfate) if disease with severe features, for delivery and 24 hr postpartum.

CHRONIC Rx

- Preeclampsia without severe features <37 wk: Close observation for worsening maternal or fetal condition, with delivery at 37 wk. If 24 to 36 wk, consider antenatal corticosteroids. If severe features develop or there is evidence of fetal compromise, earlier delivery is appropriate.
- Preeclampsia with severe features: Delivery in the presence of maternal or fetal compromise, labor, or 34 wk; at 24 to 34 wk consider steroids with very close monitoring, and at <24 wk consider termination of pregnancy. Risks of expectant management include severe worsening of disease, eclampsia, abruptio placenta, stillbirth, HELLP syndrome, ICU admission, and pulmonary edema.
- Contraindications to expectant management include eclampsia, HELLP syndrome, pulmonary edema, disseminated intravascular coagulation, abruptio placenta, uncontrollable severe hypertension, fetal demise, and nonreassuring fetal status.
- Labetalol, hydralazine, and nifedipine are the drugs of choice for long-term blood-pressure control during pregnancy.

DISPOSITION

Preeclampsia is a progressive and unpredictable disease process; a course of expectancy should be managed with caution. Up to 20% of patients who have seizures are normotensive.

The reoccurrence rate for preeclampsia in a subsequent pregnancy is approximately 20%, and higher in cases with a second trimester presentation or complications. This risk may be decreased with the use of low-dose aspirin.

REFERRAL

Obstetric management is indicated because of the insidious nature of the disease, with transfer of all cases <34 wk to a facility with appropriate maternal and neonatal care facilities.

PEARLS & CONSIDERATIONS

COMMENTS

- Low-dose aspirin, beginning as early as the second trimester, decreases the risk of preeclampsia, preterm birth, and intrauterine growth retardation in women who are at high risk of preeclampsia. The American College of Obstetricians and Gynecologists (ACOG) and the U.S. Preventive Services Task Force (USPSTF) recommend the use of low-dose aspirin as preventive medication starting after 12 wk of gestation (ideally before 16 wk) in women who are at high risk for preeclampsia (previous preeclampsia, multifetal gestation, chronic hypertension, type 1 or 2 diabetes, renal disease, or autoimmune disease).
- The use of low-dose aspirin, 150 mg/day started at 11 to 14 wk gestation, has been demonstrated to decrease the incidence of preterm preeclampsia in a selected high-risk population.[2] In the U.S., low-dose aspirin is available as an 81 mg tablet. U.S. clinicians who recommend aspirin for preeclampsia prevention could consider prescribing two 81 mg tablets daily.
- Although the absolute risk of end-stage renal disease (ESRD) in women who have had preeclampsia is low, preeclampsia is a marker for an increased risk of subsequent ESRD.
- The development of preeclampsia may be one of the earliest identifiable risk markers for potential future cardiovascular disease in women. It has been shown that women who develop preeclampsia have a higher incidence of cardiovascular risk factors including components of the metabolic syndrome within 1 yr of delivery. Women with a history of preeclampsia, particularly preterm or recurrent, are at increased risk for cardiovascular disease and appropriate follow-up should be encouraged.

Premature Rupture of Membranes

BASIC INFORMATION

DEFINITION

Premature rupture of membranes (PROM) is defined as rupture of membranes at term before the onset of labor.

SYNONYMS

Preterm premature rupture of membranes (prior to 37 weeks)
PROM

ICD-10CM CODES

042	Premature rupture of membranes
042.113	Preterm premature rupture of membranes

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Affects approximately 8% of all pregnancies

RISK FACTORS: Intraamniotic infection, low socioeconomic status, second- and third-trimester bleeding, low body mass index, nutritional deficiencies, connective tissue disorders, maternal cigarette use, cervical conization or cerclage, short cervix, pulmonary disease in pregnancy, uterine overdistention, amniocentesis, prior history of PROM, prior history of preterm delivery

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients will classically present complaining of leakage or gush of fluid from the vagina. Patients may also present with contractions and vaginal bleeding. Additional symptoms can include fever, chills, or abdominal pain if there is concurrent infection. Ultrasound will often demonstrate oligohydramnios.

ETIOLOGY

Premature rupture of membranes at term may occur due to physiologic changes in addition to uterine contractions causing shearing forces. Although there are many risk factors for PROM, it often occurs in the absence of any known risk factor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis includes leakage of urine or vaginal discharge.

WORKUP

Sterile speculum examination demonstrating pooling of fluid in posterior fornix, visualization of fluid coming out of the cervix during Valsalva maneuver, basic vaginal pH, and characteristic fern pattern of vaginal fluid that is dried on a microscope. Table E1 summarizes bedside testing for premature rupture of membranes.

Care should be taken to avoid any procedure that may introduce infection, so digital examination should be avoided unless patient is in active labor or delivery is imminently planned. This is of particular importance in preterm PROM.

LABORATORY TESTS

- pH test: Sample vaginal fluid from posterior fornix. Normal vaginal pH is 4.5 to 6.0. pH of amniotic fluid is 7.1 to 7.3. False-positive test can occur in presence of blood or semen, antiseptic or bacterial vaginosis.
- Microscopy: Visualization of fern of vaginal fluid allowed to dry on the microscope slide. False-positive test can occur if cervical mucus is sampled.
- Commercially available tests: AmniSure and other tests such as free fetal fibronectin (FFN) are available and demonstrate good sensitivity and specificity; however, per the American College of Obstetrics and Gynecology, these should be considered ancillary to standard evaluation.

IMAGING STUDIES

- Abdominal ultrasound: Evaluation of amniotic fluid volume either by maximum vertical pocket or amniotic fluid index. Oligohydramnios or low fluid volume in itself should not be considered diagnostic of PROM.
- Amniotic fluid dye test: This is considered the gold standard in diagnosis of PROM, used in clinical scenario of suspected preterm PROM with equivocal testing. Indigo carmine dye is injected via ultrasound guidance into the amniotic sac, and diagnosis made if blue dye passes into vagina.

TREATMENT

NONPHARMACOLOGIC THERAPY

All patients with PROM should have prompt evaluation of gestational age, fetal well-being via NST monitoring, and fetal presentation. In a patient with evidence of intraamniotic infection or fetal distress, prompt delivery is recommended. Close monitoring and consideration of delivery is recommended if there is concern for placental abruption. Collect swab for evaluation of GBS status and gonorrhea/chlamydia.

ACUTE GENERAL Rx

Term PROM:

- At 37.0 weeks' gestation or more, delivery is recommended for all women with ruptured membranes. Induction of labor has been shown to decrease time to delivery, risk of chorioamnionitis, endometritis, and NICU admissions, with no increase in rate of operative delivery.
- A period of expectant management can be offered in select patients who decline induction and have been appropriately counseled.
- Routine induction agents may be used. The most researched agents for induction in setting of PROM include oxytocin and prostaglandins. Oxytocin has been shown to be associated with lower rates of chorioamnionitis. Infection is also a concern with mechanical methods of cervical ripening, such as Foley balloon, but decision for induction method should be made on a case-by-case basis.
- GBS prophylaxis should be provided in GBS-positive individuals or individuals with GBS-unknown status and concurrent risk factors.

Preterm PROM:

- 34 weeks or above: Clinician should proceed toward delivery as in term patients. Administration of betamethasone for fetal lung maturity as indicated by Antenatal Late Preterm Steroids trial. Steroids should not be administered if patient has already received a course
- 24 to 34 weeks:
  1. Administration of betamethasone for fetal lung maturity
  2. Administration of prophylactic antibiotics to prolong latency period, consisting of 7-day course of parenteral and oral therapy. Current guidelines recommend ampicillin or amoxicillin and erythromycin
  3. Expectant management until 34 weeks, unless fetal lung maturity is demonstrated between 32 to 34 weeks
  4. Magnesium sulfate administration if delivery is imminent and <32 weeks
- GBS prophylaxis in setting of GBS unknown/GBS positive if delivery is expected

CHRONIC Rx

Hospitalization with expectant management is recommended for all patients with preterm PROM. Ongoing maternal and fetal surveillance in a hospital setting allows for quick recognition of infection, labor, or fetal compromise secondary to cord compression.

DISPOSITION

- Most women with preterm PROM will proceed to deliver within one week despite medical interventions. Latency period is generally longer when PROM occurs at an earlier gestational age.

TABLE E1 Bedside Testing for Premature Rupture of Membranes

Method	Result
Nitrazine	Amniotic fluid (pH >6.5) will turn nitrazine paper blue; normal vaginal secretions (pH <5.5) will leave nitrazine paper yellow.
Ferning	Amniotic fluid crystallizes.
Smear combustion	Amniotic fluid, when flamed, turns white and crystallizes.
	Vaginal secretions caramelize and turn brown.

From Marx J et al: *Rosen's emergency medicine: concepts and clinical practice,* ed 7, Philadelphia, 2010, Mosby.

- Clinical chorioamnionitis develops in 13% to 16% of preterm PROM. This risk is increased with earlier PROM as well as with an increase in the number of digital vaginal examinations.
- Complications of preterm PROM are related mostly to complications of prematurity, and decrease with increasing gestational age at time of delivery. The most common complications include respiratory distress, neonatal infection, intraventricular hemorrhage, and necrotizing enterocolitis.
- There is a 1% to 2% risk of antenatal demise in the setting of preterm PROM.

REFERRAL

Consultation with an Ob-Gyn or maternal fetal medicine specialist is recommended in the setting of preterm PROM.

PEARLS & CONSIDERATIONS

PREVENTION

Patients with a history of preterm delivery (with or without PROM) may benefit from administration of progesterone supplementation in future singleton pregnancy starting at 16 to 24 weeks to prevent preterm delivery.

Premenstrual Dysphoric Disorder

BASIC INFORMATION

DEFINITION

The *Diagnostic and Statistical Manual of Mental Disorders,* 5th edition, requires as criteria for definition of premenstrual dysphoric disorder (PMDD) the presence of five or more of the following symptoms in most menstrual cycles for the past yr.

- The symptoms should be present most of the time during the last wk of the luteal phase, with remission beginning within a few days after the onset of the follicular phase, and absent during the wk after menses. One or more of the following symptoms must be present:
  1. Marked depressed mood, feeling of hopelessness, or self-deprecating thoughts
  2. Marked anxiety, tension, feeling of being "keyed up" or "on edge"
  3. Marked affective lability (e.g., feeling suddenly sad or tearful or increased sensitivity to rejection)
  4. Persistent and marked anger or irritability or increased interpersonal conflicts
- One (or more) of the following symptoms must additionally be present to reach a total of five symptoms when combined with symptoms 1 through 4 noted previously:
  1. Decreased interest in usual activities (e.g., work, school, friends, hobbies)
  2. Subjective sense of difficulty in concentrating
  3. Lethargy, easy fatigability, or marked lack of energy
  4. Marked change in appetite, overeating, or specific food cravings
  5. Hypersomnia or insomnia
  6. A subjective sense of being overwhelmed or out of control
  7. Other physical symptoms, such as breast tenderness or swelling, headaches, joint or muscle pain, a sensation of "bloating," or weight gain
- The disturbance markedly interferes with work or school or with usual social activities and relationships with others (e.g., avoidance of social activities, decreased production and efficiency at work or school).
- The disturbance is not merely an exacerbation of the symptoms of another disorder, such as major depressive disorder, panic disorder, dysthymic disorder, or a personality disorder (although it may be superimposed on any of these disorders).
- The first three criteria must be confirmed by prospective daily ratings during at least two consecutive symptomatic cycles (diagnosis may be made provisionally before such confirmation).
- The symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, other treatment) or another medical condition (e.g., hyperthyroidism).

NOTE: In menstruating women, the luteal phase corresponds to the period between ovulation and the onset of menses, and the follicular phase begins with menses. In nonmenstruating women (e.g., women who have had a hysterectomy), determination of the timing of the luteal and follicular phases may require measurement of circulating reproductive hormones.

ICD-10CM CODE
N94.3 Premenstrual tension syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- PMDD affects 3% to 5% of women of reproductive age.
- Genetic factors play a significant role (increased incidence in monozygotic twins and in women whose mothers had PMDD).
- 30% to 76% of women with PMDD have a lifetime history of depression.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination may be completely normal.
- Depressed mood, tachycardia, sweating from comorbid disorders (e.g., panic disorder, major depression) may be present.
- Symptoms occur during the last half of the menstrual cycle (the luteal phase) and are absent from the first day of menstruation until ovulation (follicular phase).

ETIOLOGY

- Unknown. Serotonin deficiency and altered sensitivity in serotoninergic system in response to phasic hormone fluctuations in the menstrual cycle are believed to play a role.
- Progesterone appears to be the main precipitating factor in PMDD symptoms, but estrogen may also provoke symptoms.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Premenstrual syndrome
- Dysthymic syndrome
- Personality disorder
- Panic disorder
- Major depressive disorder
- Hyperthyroidism
- Polycystic ovarian syndrome
- Drug or alcohol abuse
- Irritable bowel syndrome
- Endometriosis

WORKUP

- Diagnosis is based on obtaining a detailed history and ruling out the presence of physical or psychiatric disorders. No objective diagnostic tests exist.
- The diagnosis should be confirmed by using a symptom checklist prospectively for two consecutive menstrual cycles. Commonly used diagnostic instruments include the Calendar of Premenstrual Experiences, the Premenstrual Syndrome Diary, and the Daily Record of Severity of Problems (DRSP).

LABORATORY TESTS

- None are usually necessary.
- A serum thyroid-stimulating hormone test to exclude thyroid problems, complete blood count to rule out anemia, and a chemistry profile to assess electrolytes may be ordered if diagnosis is unclear.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Reduction in intake of caffeine, refined sugars, or sodium may be helpful in some patients.
- Increased aerobic exercise, smoking cessation, alcohol restriction, and regular sleep are often beneficial.
- Stress reduction and management will decrease severity of symptoms.
- Cognitive behavior therapy may also be helpful for reducing symptoms.

GENERAL Rx

- Selective serotonin reuptake inhibitors are useful for the treatment of PMDD. Commonly used agents and initial doses are fluoxetine 10 mg qd, sertraline 50 mg qd, paroxetine 10 mg qd, and citalopram 20 mg qd. Many patients will require titration to significantly higher doses to achieve therapeutic benefit. These medications can be administered continuously during the menstrual cycle or only when the patients experience symptoms. Luteal phase or intermittent administration involves initiating medication at the time of ovulation and stopping it at the beginning of menses. Serotonin-norepinephrine reuptake inhibitors (SNRIs) such as venlafaxine may also be effective in women with predominantly psychological symptoms.
- Other useful agents are benzodiazepines (alprazolam 0.25 mg tid prn) and the tricyclic antidepressant clomipramine (25 mg qd as starting dose).
- Gonadotropin-releasing hormone (GnRH) agonists are effective in treating patients with PMDD. The accelerated bone loss and vasomotor symptoms associated with long-term use of a GnRH agonist will require add-back therapy. Hormonal intervention with monthly intramuscular injections of leuprolide has been reported effective in some patients; however, it should be reserved only for patients unresponsive to first- and second-line agents.
- Nutritional supplementation (vitamin B_6 up to 100 mg/day, vitamin E up to 600 IU/day, calcium carbonate up to 1200 mg/day, and magnesium up to 500 mg/day) are also commonly used for symptom reduction in some patients with limited results.
- Ovariectomy may be considered in severe refractory cases.

Premenstrual Syndrome (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

SUGGESTED READINGS

American Psychiatric Association. *Desk reference to the diagnostic criteria from DSM-5.* American Psychiatric Association: Arlington, VA.

Biggs WS, DeMuth RH: Premenstrual syndrome and premenstrual dysphoric disorder, *Am Fam Physician* 84(8):918-924, 2011.

Hofmeister S, Bodden S: Premenstrual syndrome and premenstrual dysphoric disorder, *Am Fam Physician* 94(3):236-240, 2016.

BASIC INFORMATION

DEFINITION

Premenstrual syndrome (PMS) consists of various somatic and physical complaints that develop during the luteal phase of the menstrual cycle and that are of sufficient severity to interfere with daily functioning and/or interpersonal relationships. The symptoms resolve shortly after the onset of menses.

SYNONYM

PMS

ICD-10CM CODE
N94.3 Premenstrual tension syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- Premenstrual disorders affect about 12% of reproductive-age women, although as many as 80% of women will report at least one somatic or affective symptom during their luteal phase (Table 1).
- Severe cases of premenstrual dysphoric disorder (PMDD), which is more of a psychiatric diagnosis, occur in approximately 1.3% to 5.3% of women.
- The prevalence of PMS is not associated with age, race, or socioeconomic status.
- Those seeking treatment for PMS are usually in their 30s or 40s.
- Based on some identical twinning studies, a genetic component is thought to exist, but no genes have been identified.
- The natural history of PMS has not been clearly elucidated.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Diverse and potentially disabling symptoms. Table 1 summarizes common symptoms of PMS
- Associated with multiple psychological, physical, and behavioral symptoms
- Most frequent reason for seeking treatment: Emotional symptoms
- Most common emotional symptoms: Depression, irritability, anxiety, labile moods, anger, crying easily, sadness, extreme sensitivity, nervous tension
- Most common physical symptoms: Headache, bloating, cramps, breast tenderness, migraines, fatigue, weight gain, aches and pains, palpitations
- Most common behavior symptom: Food cravings
- Other behavioral symptoms: Increased appetite, increased alcohol intake, decreased motivation, decreased efficiency, avoidance of activities, staying home, sleep changes, libido changes, forgetfulness, decreased concentration

ETIOLOGY

- Etiology is poorly understood. The syndrome is thought to result from steroid hormone effects on serotonin, ϒ-aminobutyric acid, dopamine systems, and the renin-aldosterone system, thus causing some of the bloating symptoms.
- Because of the multifactorial, multiorgan nature of PMS, a single etiologic cause is unlikely.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- A diagnosis of exclusion, so other medical or psychological disorders should be ruled out
- Common disorders to rule out: Depression or anxiety, anemia, migraines, endometriosis, thyroid disease

WORKUP

- History.
- Physical examination.
- Laboratory studies to rule out alternative diagnosis.
- If no alternative diagnosis, confirm by either history of regular menses, basal body temperature charting, or elevated luteal progesterone that patient is ovulatory.
  1. If she is not ovulating, it is not PMS.
  2. A prospective questionnaire given over two menstrual cycles has been found to be the most accurate way to assess the presence of PMS or PMDD. If symptoms are not occurring only in the luteal phase, it is not PMS, and further investigation is needed.
     a. If symptoms occur in the follicular phase, patient has premenstrual exacerbation of another condition.
     b. If symptoms do not occur in the follicular phase, diagnosis of PMS is confirmed.

LABORATORY TESTS

- None available to specifically confirm the diagnosis of PMS
- Thyroid function tests to rule out thyroid disease

TREATMENT

NONPHARMACOLOGIC THERAPY

- Individualization of the treatment plan to maximize therapeutic response.
- Psychosocial intervention:
  1. Education
  2. Stress management
  3. Environmental changes
  4. Adequate rest and sleep
  5. Regular exercise
- Nutritional recommendations:
  1. Regularly eaten, well-balanced meals
  2. Adequate amounts of protein, fiber, and complex carbohydrates; low fat
  3. Avoidance of foods that are high in salt and simple sugars; may promote water retention, weight gain, and physical discomfort
  4. Avoidance of alcohol and illicit drugs; may worsen emotional lability
  5. Calcium supplementation (1000 mg/day for women 19 to 50 yr, 1300 mg/day for girls 14 to 18 yr) to reduce the physical and emotional symptoms
  6. The data are mixed regarding the benefits of vitamin D supplementation in reducing PMS symptoms, so more studies are needed
  7. Pyridoxine (vitamin B_6) 80 mg qd to improve depression, fatigue, and irritability has been suggested in small studies

ACUTE GENERAL Rx

Suppression of ovulation:

- Oral contraceptives: One pill per day; continuous use associated with better treatment effect
- Progestin-only oral contraceptive: One pill per day
- Oral micronized progesterone: 100 mg every morning and 200 mg every evening on days 17 through 28 of menstrual cycle
- Progestin suppository: 200 to 400 mg bid on days 17 through 28 of menstrual cycle
- Medroxyprogesterone: 150 mg IM q3mo
- Levonorgestrel implants: Surgical insertion every 5 yr

TABLE 1 Common Symptoms of Cyclic Premenstrual Syndrome

Somatic Symptoms	
Abdominal bloating	Constipation or diarrhea
Acne	Headache
Alcohol intolerance	Peripheral edema
Breast engorgement and tenderness	Weight gain
Clumsiness	
Emotional and Mental Symptoms	
Anxiety	Insomnia
Change in libido	Irritability
Depression	Lethargy
Fatigue	Mood swings
Food cravings (especially salt and sugar)	Panic attacks
Hostility	Paranoia
Inability to concentrate	Violence toward self and others
Increased appetite	Withdrawal from others

From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

- Transdermal estradiol: One or two 100-μg patches every 3 days
- Danazol: 100 to 200 mg/day (ovulation not suppressed at this dose); has significant side-effect profile
- Gonadotropin-releasing hormone (GnRH) agonists: Daily by intranasal spray or monthly by depot injection; profound hypoestrogenism, concerns for osteoporosis and vasomotor symptoms

Suppression of physical symptoms:

- Spironolactone: 25 to 50 mg bid on days 14 through 28 of menstrual cycle—need a reliable form of birth control
- Mefenamic acid
  1. For fluid retention: 250 mg tid on days 24 through 28 of cycle
  2. For pain: 500 mg tid on days 19 through 28 of cycle
- Bromocriptine: 5 mg/day on days 10 through 26 of cycle
- Naproxen: 550 mg bid on days 17 through 28 of cycle, Naprosyn-500 mg bid on days 17 through 28 of cycle

Suppression of psychological symptoms:

- SSRI, or serotonergic antidepressants, are first-line treatment for PMS/PMDD, treating mostly the psychological aspects but also some physical aspects
- Sertraline, paroxetine, fluoxetine, citalopram, escitalopram
- In 2013 the *Cochrane Reviews* reported a statistically significant benefit over placebo when taken either continuously or in the luteal phase
- Serotonin-norepinephrine reuptake inhibitors (SNRI) such as venlafaxine; use is off-label, but onset of action is quick and has been found to be helpful
- Seroquel: Smaller studies
- Wellbutrin: Not as effective as the other options

CHRONIC Rx

- Therapy is largely trial and error, with the goal of providing effective treatment with the safest therapy. Provider should initially attempt to ameliorate the most pronounced symptom(s).
- Limited evidence exists that acupuncture and/or acupressure may ameliorate some symptoms associated with PMS and improve quality of life. More studies are needed to determine if this option is as good as or better than conventional therapies such as treatment with an SSRI.
- For severe intractable PMS: Bilateral oophorectomy; give trial of GnRH therapy or danazol before surgery (bilateral oophorectomy should be exceedingly rare).
- Estrogen replacement therapy recommended postoperatively to reduce the risk of osteoporosis, heart disease, and genitourinary atrophy.

DISPOSITION

Improved symptoms in 90% of women over time

REFERRAL

- For counseling with a psychologist or psychiatrist if underlying psychiatric disorder is discovered (cognitive-behavioral therapy)
- To a gynecologist if surgical therapy is contemplated

BASIC INFORMATION

DEFINITION

The 2016 National Pressure Ulcer Advisory Panel (NPUAP) defines pressure injury (previously pressure ulcer) as a localized area of damage to the skin and/or underlying soft tissue over a bony prominence or related to a medical or other device. This occurs as a result of intense or prolonged pressure or pressure in combination with shear and friction. The tolerance of soft tissue for pressure and shear may also be affected by other factors such as microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue. Common sites include the sacrum, heels, elbows, lateral malleoli, occiput, scapula, ischium, and calcaneus among others. It can present as an intact skin or an open ulcer that could be painful. This revised nomenclature allows for the recognition of lesser degrees of skin damage that are not necessarily associated with pressure injuries.

SYNONYMS

Decubitus ulcers
Pressure sores
Bed sores
Pressure ulcers
Pressure-induced skin injury
Pressure-induced soft tissue injury

ICD-10CM CODES

L89 Pressure ulcers

Subcategories of codes determined by stage and location of ulcer

L89.153 Example: Stage 3 ulcer of sacral area

New codes for Deep Tissue Injury [DTI]: introduced 10/1/19 for all patient encounters and discharges. Determined by location:

L89.016 Example: Pressure-induced deep tissue damage of the right elbow

EPIDEMIOLOGY & DEMOGRAPHICS

- An estimated 2.5 million cases of pressure injuries are treated each yr in acute care facilities across the U.S.
- Worldwide, the prevalence of pressure injury in the acute care setting ranges from 6% to 18%.
- Pressure injuries resulted in 28,500 documented deaths globally in 2013, more than double from 13,700 deaths in 1990.
- Development of pressure injury results in increased hospital length of stay by 7 to 10 days. These patients are three times more likely to be discharged to long-term care facilities.
- In the U.S., the Centers for Medicare and Medicaid (CMS) does not provide any reimbursement to hospitals for treatment of stage 3 and 4 pressure injuries acquired during hospitalization.
- In 2016, the national cost for pressure injury management was $22 billion. Hospital-acquired pressure injuries added $8200 to the cost of the surgical stay, which conferred an additional 44% increase in surgical stay costs.
- Patients who develop pressure injuries tend to be older patients (mean age of 71 yrs), debilitated, immobile, and have multiple medical problems such as dementia, lung disease, diabetes mellitus, urinary or fecal incontinence, and nutritional deficiencies to include a few. A cohort study observed that pressure injuries occurred in 36% of older patients with hip fracture.
- Occur in all health care settings including hospitals, nursing homes, and residential homes. The reported rates upon admission to a nursing home range from 10% to 35%. The incidence rate is highest in institutions with lower staffing levels of registered nurses and certified nursing assistants, reflecting the importance of health care resources rather than medical decision-making.
- Associated with impaired quality of life and significant morbidity and mortality. 1-yr mortality rate approaches 40%, and if complicated by bacteremia may exceed 55%. Emotional and psychological trauma often accompany pressure injury, leading to more significant reduction in overall well-being and quality of life.
- Significant pain occurs in two thirds of patients with stage 2 or greater pressure injury.

CLINICAL PRESENTATION

There are a number of staging systems that have been developed and utilized to describe the stages of pressure injury. The most commonly used system is from the National Pressure Ulcer Advisory Panel (NPUAP). The European Pressure Ulcer Advisory Panel (EPUAP) recommends similar staging except for the presence of suspected deep tissue injury and unstageable ulcers. The staging of the wound should be based according to the extent or depth of injury. Common locations of pressure injury have been demonstrated in the following settings: supine position, prone position, lying in bed with head elevated, and sitting position. In order of prevalence, sites most commonly involved are those over the sacrum, calcaneus, ischium, and greater trochanter. In general, up to 75% of all pressure injuries are located around the pelvic girdle. Heel is the second most common site after the sacrum and the most common site in the case of suspected deep tissue injuries.

The NPUAP 2016 guidelines (Fig. 1) described the staging system as follows:

- **Stage 1 pressure injury: Nonblanchable erythema of intact skin.** Skin is intact with a localized area of nonblanchable erythema, which may appear differently in patients with darkly pigmented skin color. The presence of blanchable erythema or changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration; these may indicate deep tissue pressure injury.
- **Stage 2 pressure injury: Partial-thickness skin loss with exposed dermis.** The wound bed is viable, pink or red, moist, and may also present as an intact or ruptured serum-filled blister. Adipose tissue (fat) is not visible, and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe moisture-associated skin damage, including

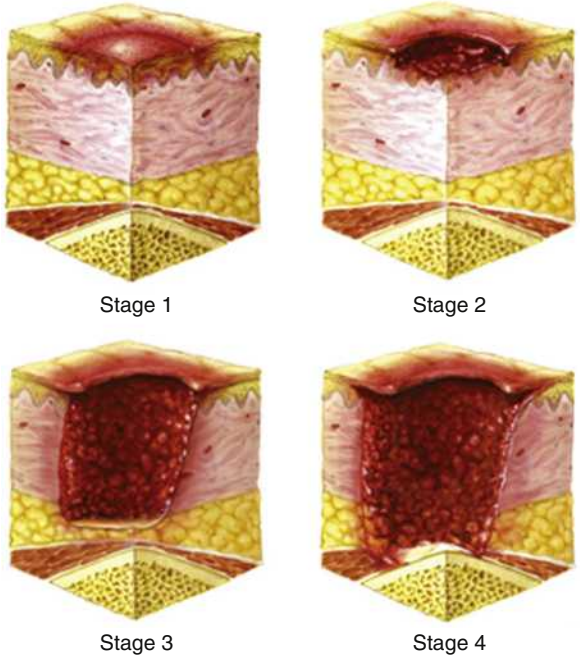

FIG. 1 Staging of pressure ulcers. Used with permission of the National Pressure Ulcer Advisory Panel. (From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, Elsevier.)

incontinence-associated dermatitis, intertriginous dermatitis, medical adhesive–related skin injury, or traumatic wounds (skin tears, burns, abrasions).

- **Stage 3 pressure injury: Full-thickness skin loss.** At this stage there is full-thickness loss of skin with adipose tissue visible in the ulcer; granulation tissue and epibole (rolled wound edges) are often present. Slough and/or eschar may be visible. The depth of tissue damage varies by anatomical location; areas of significant adiposity can develop deep wounds. Undermining and tunneling may occur. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury. The depth of a stage 3 pressure injury varies by anatomic location.
- **Stage 4 pressure injury: Full-thickness skin and tissue loss.** At this stage there is full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone in the ulcer. Slough and/or eschar may be visible. Epibole (rolled edges), undermining, and/or tunneling often occur. Depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury. The extent of stage 4 ulcers is often underestimated due to undermining and fistula formation. A relatively small superficial defect may mask extensive tissue necrosis.
- **Unstageable pressure injury: Obscured full-thickness skin and tissue loss.** Unstageable pressure injury is full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed.
- **Deep tissue pressure injury: Persistent nonblanchable deep red, maroon, or purple discoloration:** New ICD-10 subcategory for DTPI: separates this category of pressure injury from unstageable wounds.
  1. Deep tissue pressure injury consists of intact or nonintact skin with a localized area of persistent nonblanchable deep red, maroon, or purple discoloration, or with epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature changes often precede skin color changes. Discoloration may appear differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone-muscle interface. Early stage deep tissue pressure injuries do not have an outer layer of slough or eschar and are not debrided. The wound may evolve rapidly to reveal the actual extent of tissue injury, or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures are visible, a full-thickness pressure injury is present (unstageable, stage 3 or stage 4). Deep tissue pressure injury should not be used to describe vascular, traumatic, neuropathic, or dermatologic conditions.
  2. Deep tissue injury (DTI) prevalence is highest in the ICU. It accounts for about 14% of all ulcers. Common areas affected include coccyx, sacrum, buttocks, and heels.
- **Medical device–related pressure injury:** Medical device–related pressure injuries (MDR PIs) result from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant pressure injury generally conforms to the pattern or shape of the device. The most commonly implicated medical devices include splints, braces, tubing, and respiratory devices. Prevention is an indicator of quality care. The nature of the devices used, anatomical site involved, and condition of the patient often present a challenge to prevention and treatment. A meta-analysis of 29 studies with a mean age of 39 in adults and 5.9 in children showed a pooled 12% incidence and 10% prevalence rate in hospitalized patients. Analysis of the 2016 International Pressure Ulcer Prevalence Data in Canada and the US included acute care, long-term care, subacute care, long-term acute care hospitals, and hospice. This large database identified a prevalence rate of 0.6% MDR PIs, including mucosal and nonmucosal MDRs. 75% of these were facility-acquired. Over half (>50%) were stage 1 to 2, 22% stage 3 to 4, and 15% deep tissue PI. These injuries tend to form up to 3 days faster than non-MDR pressure injuries. The most common site is the ears, associated with respiratory cannulas, tubings and masks. Another common site is the feet, associated with casts and splints. The resultant pressure injury generally conforms to the pattern or shape of the device. The injury should be classified using the staging system.
- **Mucosal membrane pressure injury:** Mucosal membrane pressure injury is found on mucous membranes with a history of a medical device use at the location of the injury. Due to the anatomy of the tissue, these ulcers cannot be staged. Unique characteristics of mucosa include difficulty to detect non-blanchable erythema and absence of scar formation that in turn lead to an underappreciation of the severity of the injuries.
- **Incontinence-associated dermatitis (IAD):**There is intense and diffuse erythema of specific sites such as perineum, buttocks, and inner thighs. Associated symptoms include itching, burning sensation, pain, and concomitant fungal infections. The presentation can be varied. This includes ulcers with diffuse and irregular edges, papules, scaling, and weeping lesions. These are not classified as pressure injuries, however serve as a significant risk factor for the evolution to pressure injury.

PATHOGENESIS

The development of a pressure injury is a complex interaction of external forces and host-specific (intrinsic) factors. These forces include pressure, friction, shear, and moisture. Pressure applied to the skin in excess of the arteriolar pressure of 32 mm Hg prevents the delivery of oxygen and nutrients to tissues, leading to tissue hypoxia, accumulation of metabolic waste products, and free radical generation. The tolerance of soft tissue for pressure and shear may also be affected by immobility, microclimate factors, nutrition, perfusion, incontinence, comorbidities (including sensory perception disorders), and the condition of the soft tissue. The 2016 NPUAP consensus statement identified risk factors in specific situations that may lead to the development of unavoidable pressure injuries. These include the following: impaired tissue oxygenation, cardiovascular instability, hypovolemia, sepsis, anasarca, peripheral vascular disease, sensory impairment, immobility, end-of-life skin failure, and multi-organ failure. Body mass index (BMI) has an important role in the risk for pressure injury. Underweight (BMI <19 kg/m^2) and morbidly obese (BMI >40 kg/m^2) patients are at high risk for pressure injury formation. Other contributing mechanisms for the development of pressure injury include reperfusion injury, increased capillary permeability, soft tissue edema, lymphatic impairment, direct mechanical cellular injury, up-regulated autophagy, and accelerated cell senescence. Diseases that affect tissue perfusion such as peripheral vascular disease, diabetes mellitus, and heart failure pose a heightened risk for pressure injury development. However, it is important to note that patients with poor hemodynamics in addition to liver failure, sepsis, and acute respiratory distress syndrome may present with acute skin failure (ASF) rather than pressure injury. This is most commonly observed in the ICU setting.

Unlike other wounds, pressure injuries do not often follow the normal phases of healing (i.e. initial inflammatory phase, proliferative phase, and final remodeling and maturation phase). Instead, they become arrested in the inflammatory phase.

Complications of untreated pressure injuries include cellulitis, abscess formation, sinus tract formation, heterotopic calcification, systemic amyloidosis from chronic inflammation, rhabdomyolysis, and malignant transformation such as squamous cell cancer, particularly in a non-healing pressure injury.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Venous insufficiency ulcers
- Arterioocclusive ulcers
- Diabetic foot ulcers
- Neuropathic ulcers
- Skin cancer
- Cellulitis and erysipelas
- Skin abscess
- Kennedy terminal ulcers (KTU)
- Acute skin failure (ASF)
- Incontinence-associated dermatitis (IAD)
- Perineal dermatitis
- Device-related pressure injury

WORKUP

- A comprehensive assessment targeting source identification, contributing factors, underlying comorbidities, and other elements affecting wound healing should be implemented.
- A proper documentation of wound history is a must. This includes onset, duration, prior treatments, and procedures.
- A thorough physical examination of the identified areas of skin damage and of a minimum of 4 cm of periwound tissue should be performed.
- These areas should be evaluated for their length, width, and depth and for the presence of sinus tracts, undermining, tunneling, fistulas, exudate, and necrotic tissue as well as any evidence for healing such as the formation of granulation tissue.
- Adequate documentation such as the use of photographs for comparison can be extremely helpful to track changes over time.
- It is essential to rule out infection, as this would impair wound healing. The presence of cellulitis, abscess, and osteomyelitis should be explored.

LABORATORY TESTS

- Directed at identifying causes, risk factors, and/or any complications arising from the pressure injury (e.g., abscess or osteomyelitis).
- Cultures of wound bed are not believed to be helpful and should be avoided. Deep tissue biopsy is the gold standard to rule out osteomyelitis.
- Potentially useful markers for nutritional status include prealbumin, albumin, transferrin, lymphocyte count, and total cholesterol level.
- Complete blood count may be obtained if systemic infection is suspected.

IMAGING STUDIES

- Ultrasound is not proven to be effective.
- Plain radiographs, MRI, and triple-phase bone scan may help identify osteomyelitis when clinically suspected. A comparison study of 44 patients scheduled for open biopsy showed that MRI has superior diagnostic benefit over plain radiography.

Rx PREVENTION & TREATMENT

- The most effective strategies for prevention and resolution of pressure injuries are designed to provide a systematic approach involving risk assessment, continuous monitoring, education, and multiple interventions.
- Conduct a structured and individualized risk assessment on a regular basis, especially when the clinical condition changes.
- Identify high-risk patients using standardized risk assessment scales and risk prediction tools (e.g., Braden and Norton in the US; Waterlow scale in the UK; Cubbin and Jackson scale for ICU patients).
- Use standardized assessment tools to monitor wound healing on a weekly basis. Examples include the Pressure Sore Status Tool (PSST), Pressure Ulcer Scale for Healing (PUSH), Wound Healing Scale, and the Sessing Scale. The PUSH tool in conjunction with the NPUAP staging system is the most readily applied tool.
- Use of prophylactic dressings in high-risk patients is being studied in small randomized pilot studies in the U.S. and Australia. Foam and silicone dressings may be promising and cost-effective. However, no consensus has been reached.
- Focus on controlling the microclimate (moisture and temperature).
  1. Minimize prolonged skin exposure to moisture, urine, or stool.
  2. Treat dry, cracked skin.
- Use of repositioning and pressure-reducing devices (e.g., foam mattresses, air-fluidized beds, low–air loss beds, pillows, gel pads, or foam wedges when in bed or in a chair).
  1. Patient repositioning (based on individual tissue tolerance): Current studies assume repositioning is effective for prevention and healing. Focus is on education, positioning devices, most effective position, and turning frequency. Studies range from basic techniques and devices such as pillows to pressure mapping imaging and ultrasound to detect changes indicating deep tissue injury. Pilot studies continue in acute care hospitals, critical care, rehabilitation facilities, nursing homes, and in home-bound populations.
  2. Bed surface:
     a. There is consensus that pressure-reducing mattresses are effective in prevention and healing of pressure injuries compared with standard bed surfaces. Data comparing reactive vs. nonreactive support surfaces are inconsistent and inconclusive.
     b. Two randomized controlled trials (RCTs) found that use of air-fluidized beds contributed to the healing of a greater number of pressure injuries after 15 days compared with standard care.
     c. A systematic review revealed no differences in the rate of pressure injury healing with the use of either alternating-pressure mattresses or low air-loss beds compared with standard care. A small Belgian prospective RCT compared a static air mattress vs alternating pressure mattress in high risk, bed or chair-dependent nursing home residents over age 65. Results noted pressure injuries presented 50% sooner in the alternating pressure mattress group compared with the static air mattress.
  3. Support surface:
     a. The first meta-analysis of support surfaces and pressure injury prevention concluded with moderate certainty that powered active air surfaces and powered hybrid air surfaces probably reduced the incidence of pressure injuries by 58% and 78% when compared with standard hospital surfaces.
     b. There is low certainty that nonpowered reactive surfaces reduce pressure injuries.
     c. Based on the results of 19 RCTs, a Cochrane Review concluded based on current evidence: no support surface is more effective at healing pressure injuries than standard support surfaces.
     d. Pressure-relieving overlays: One RCT demonstrated that a viscoelastic pad on the operating table significantly reduced incidence of postoperative pressure injuries compared with a standard operating table.
     e. Use adequate support surfaces while in bed or in a chair to prevent "bottoming out" (defined as less than 1 inch between patient and support surface; measured by putting hand under support surface and feeling thickness to patient).
  4. Foam alternatives:
     a. Forty-one RCTs demonstrated that patients lying on standard hospital mattresses are more likely to develop pressure injuries than those patients lying on higher-specification foam mattresses.
- Recent systematic review of pressure injury prevention strategies showed poor methodology in most studies. Use of support surfaces, repositioning, optimized nutrition, and sacral skin moisturizing was most appropriate.

NONPHARMACOLOGIC THERAPY

- Pressure injuries should be cleaned at each dressing change.
- Avoid agents that are cytotoxic to epithelial cells (e.g., iodine, iodophor, sodium hypochlorite, hydrogen peroxide, acetic acid, alcohol).
- Wound irrigation should not exceed 15 psi and is best done with an 18-gauge angiocatheter. Necrotic tissue should be debrided quickly because it delays wound healing and increases risk of infection.

- Do not debride hard, dry, stable eschar on heels or ischemic limbs.
- No single dressing or product is superior; keep wound bed moist and protect it from urine/stool. Silver dressings, topical phenytoin, and growth factors should be limited to difficult-to-heal wounds, chronic ulcers, and extensive burns given their extra cost and limited scientific validation. Reduce pressure by using foam mattress, dynamic support surface (e.g., low–air loss bed), and frequent repositioning (e.g., every 2 hours or, in case of poor perfusion, more frequently).
- Hyperbaric oxygen therapy when used for some wounds provided temporary benefit. There have been no studies specifically looking at treatment of pressure injuries. Moreover, serious adverse events such as pneumothorax and seizures can occur.
- The data on the efficacy of ultrasound as wound therapy is limited. Similarly RCTs on electromagnetic therapy found no evidence of benefit on wound healing.
- Use of topical agents such as phenytoin, becaplermin gel, sucralfate, and medicinal manuka honey showed limited evidence for the healing of stage 2 ulcers.
- Negative-pressure wound therapy (NPWT) may be useful for wounds that have significant drainage. They help improve healing by promoting angiogenesis, improving tissue perfusion, and decreasing bacterial count. Calcium alginate and foam dressings may also be beneficial for such wounds. Randomized studies have not identified any significant differences to quantitative wound healing; however, it provided some level of patient and provider comfort.
- Although controlling poor nutrition has been shown to be beneficial, a recent large investigation demonstrated that feeding tubes did not prevent or heal pressure injuries, but increased the risk for their development.
- Minimize or promptly remove urinary and/or fecal contamination.
- No RCTs have compared debridement versus no debridement in the treatment of pressure injuries.
  1. Thirty-two RCTs have compared different debridement agents, but there is insufficient evidence to promote the use of one particular agent.
  2. One RCT demonstrated pressure injuries treated with collagenase healed significantly more quickly than those treated with hydrocolloid.
  3. One RCT comparing honey-treated dressings with saline-soaked dressings showed faster healing times with the honey-treated group.
  4. A meta-analysis and one RCT found significant benefit in rates of healing with use of hydrocolloid dressings versus traditional saline gauze dressings but not over other forms such as hydrogels, foam dressings, or collagenase.
- Malnutrition is an independent risk factor for pressure injury. However no benefit was found with nutritional and vitamin supplementation for those without known nutritional deficiencies. There is inconclusive evidence that vitamin C and zinc are effective in wound healing. Data is limited to support enteral or parenteral nutrition for patients whose oral intake is inadequate.
- There is insufficient data to recommend the use of anabolic steroids such as oxandrolone therapy to promote weight gain and repletion of protein stores.

ACUTE GENERAL Rx

- The cornerstone of therapy involves the use of appropriate wound dressings, pressure-reducing devices, treatment of infection, debridement, and surgical consultation when appropriate.
- Traditional bedside debridement provides excellent results in reducing the surface area for a majority of the wounds. Sharp debridement can effectively remove devitalized tissue and is a proven significant component to advancing wound closure.
- All pressure injuries are colonized with bacteria. Clinically evident infections should be assessed with culture and treated appropriately with topical and systemic antibiotics.
- A randomized controlled trial in 2017 showed significant reduction in stage 2 to 4 pressure injuries using anode and cathode high-voltage electrical stimulation.
- Pain medications are necessary if pressure injuries are present. One study found that excruciating pain was more prevalent in nursing home residents with pressure injuries. Local factors that may be contributing to pain such as ischemia, infection, or breakdown of surrounding skin should be properly addressed.

CHRONIC Rx

- Continue vigilance with pressure reduction because pressure injuries can recur with minimal trauma.
- There are no randomized trials available to identify whether repositioning makes a difference in the healing rates of pressure injuries or what the optimal repositioning regimen should be.
- Consider radiologic evaluation for infected ulcer bed, occult osteomyelitis, or abscess.

DISPOSITION

- When systematic risk assessments are done and preventive measures are followed, most pressure injuries can be prevented. Most injuries heal when appropriate management strategies are followed.
- Stage 4 pressure injuries in high-risk patients (e.g., paraplegics) can take mos to yrs to heal.

REFERRAL

- Physical and occupational therapists to help improve bed and chair mobility, as well as basic activities of daily living
- Wounds with necrotic tissue need referral to providers trained in sharp debridement
- Role of plastic surgeons for operative repair for large stage 3 or 4 pressure injuries that do not respond to optimal care
- To a specialty wound care center for non-healing complex pressure injuries

PATIENT & FAMILY EDUCATION

- Educate patient and family members on the risk factors for pressure injury formation.
- Encourage mobility and adequate nutritional intake as well as avoidance of bed rest.
- There is a need for patient involvement and education during periods of care transition and service changes by health care providers.

Considerations for palliative wound care for pressure injuries that exist and occur in serious illness to include the end-of-life stage

- Palliative patient populations have the highest incidence of all types of wounds. Pressure injuries comprise about 60% of them.
- Pressure injuries are unavoidable at the end of life. The term SCALE (skin changes at life's end) was introduced in 2008 to describe the group of wound phenomena that result from the complex failure of homeostatic mechanisms at the end of life.
- Kennedy Terminal Ulcer (KTU) has been described in the literature as an unavoidable and rapid onset skin breakdown or skin failure that occurs as part of the dying process. It occurs in the sacrococcygeal area, heel, calf, and elbows. Its classic configuration could be shaped like a pear, butterfly, or horseshoe. In contrast, the 3:30 syndrome of KTU was coined due to the rapidity of change, i.e., the patient's skin was normal when examined in the morning and by 3:30 pm shift change, the ulcer had emerged.
- The basic steps in pressure injury management at the end of life mirror that conventional pressure injury except that the primary intent is not necessarily for wound healing. Rather emphasis on quality of life and symptom control is the overarching goal. These steps include cleansing/debridement, management of exudate, slough, or infection, protection of the periwound skin, and dead space management.
- Common wound cleansing solutions used in this population include Dakin solution, cadexomer iodine, acetic acid, and topical phenytoin. All promote some improvement in inflammation, bacterial burden, healing, odor, pain, and granulation tissue development.
- The factors associated with increased likelihood of healing include age less than 70 yr, palliative performance score >30, and in exceptional circumstances, the use of artificial nutrition for those with good performance status.

PEARLS & CONSIDERATIONS

COMMENTS

- Up to 10% of older persons will have a pressure injury.

- Because 70% of pressure injuries occur in older persons, the approach should be similar to other multifactorial geriatric syndromes with an interprofessional team approach.
- Identify and reduce all modifiable risk factors for pressure injuries.
- Treat the pain associated with pressure injuries.
- Proper skin care, use of support surfaces, mobilization, and nutritional support are integral for prevention and treatment. Of these, pressure redistribution is the most important factor for prevention.
- Effective prevention practices consist of timely wound reassessments, regular communication with team members, patient and caregiver empowerment, and utilization of clinical decision support tools for health care providers.
- Clinical studies have not revealed that any one dressing product is superior to another.
- Nonhealing pressure injuries require assessment for debridement, infection, abscess, and/or referral to a wound center.

BASIC INFORMATION

DEFINITION

Preterm labor is defined as regular contractions that result in cervical dilation or effacement prior to 37 wk gestation. Preterm birth is one that occurs after 20 wk gestation and before the completion of 37 wk gestational age.

SYNONYM

Premature labor

ICD-10CM CODES

O60.0	Preterm labor without delivery
O60.1	Preterm spontaneous labor with preterm delivery
O60.2	Preterm spontaneous labor with term delivery

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence of preterm births in the U.S. increased from 9.5% in 1981 to 12.7% in 2006 before falling gradually to 11.4% by 2013. The increase since 1981 is attributed to improvements in pregnancy dating by ultrasound, increased use of assisted reproductive technology, and increased preterm induction or preterm operative delivery for maternal or fetal indications. Between 40% and 45% of these births follow spontaneous preterm labor; either the remaining preterm births result from preterm premature rupture of membranes (PPROM), or they occur secondary to intentional delivery for maternal or fetal indications.

PREDOMINANT AGE AND RACIAL DIFFERENCES: Pregnant women at the extremes of reproductive age (<17 yr and >35 yr) are at greatest risk. Black race is one of the most significant risk factors with the rate of preterm birth averaging 18.4% between 2005 and 2007 compared to 10.8% among Asian Americans and 11.6% in white women. The disparity between African-American and other ethnic American races persists after adjusting for income, education, and other medical risk factors.

GENETICS: A genetic component has been suggested. Women with sisters who have had preterm births and women with grandparents who were born preterm may be at increased risk for having preterm deliveries themselves. Single-nucleotide polymorphisms have also been associated with preterm labor.

RISK FACTORS: Risk factors for premature labor include a prior preterm delivery, intrauterine infection, systemic or genital tract infections, periodontal disease, short interpregnancy interval (<6 mo), short cervical length (<25 to 30 mm), low pre-pregnancy body mass index (BMI) (<19.8 kg/m^2), age (<17 yr or >35 yr), a history of elective pregnancy termination, history of prior stillbirth, African-American ethnicity, vaginal bleeding, polyhydramnios or oligohydramnios, multiple gestation, structural abnormalities of the uterus, history of cervical cone biopsy or loop electrocautery excision, in vitro fertilization or ovulation induction, tobacco use, heavy alcohol consumption, cocaine use, heroin use, and psychological or social stress. The strongest historic risk factor for preterm birth is a previous birth between 16 and 36 wk gestation.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Presenting symptoms include increased pelvic pressure, abdominal cramping or contractions, increased vaginal discharge, vaginal bleeding or spotting, or leakage of fluid.

ETIOLOGY

Causes of premature labor are varied and often difficult to determine. Premature labor may be secondary to infection, systemic illness, trauma, anatomic abnormalities (i.e., uterine anomaly), or a combination of factors. It is thought that cervical ripening is the most common first step to premature labor or delivery. Subsequently, decidual-membrane activation occurs followed by contractions (Box 1).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The differential diagnosis for preterm labor should include preterm rupture of membranes, preterm contractions (contractions before 37 wk gestation that do not result in cervical change), and abdominal pain or cramping secondary to other medical conditions. There are many medical conditions that may cause preterm contractions or premature labor. Treating some of these underlying conditions may improve the prognosis for stopping the preterm labor.

Possible medical conditions include:

- Infection
  1. Chorioamnionitis
  2. Genital tract infections, including bacterial vaginosis, gonorrhea, chlamydia
  3. Urinary tract infections, including pyelonephritis, cystitis, or asymptomatic bacteriuria
  4. Gastroenteritis
- Trauma
- Placental abruption
- Illicit drug use
- Preterm premature rupture of membranes
- Appendicitis
- Nephrolithiasis
- Pancreatitis
- Cholelithiasis
- Uterine fibroids

WORKUP

- History and physical exam to rule out trauma, abuse, other causes of abdominal pain, and infection
- Fetal heart rate monitoring and tocometry to determine fetal status and contraction frequency
- Speculum exam to visually assess the cervix and assess for rupture of membranes, bleeding, infection, or advanced cervical dilation
  1. If the patient is <35 wk gestation, a Fetal Fibronectin (FFN) test should be collected prior to performing a digital exam or transvaginal ultrasound. A FFN test can help predict preterm delivery if the patient has a cervical length on transvaginal ultrasound of <30 mm
- Digital exam in the unruptured patient with normal placentation to determine cervical dilation and effacement, and fetal station

LABORATORY TESTS

- CBC
- Urine analysis and culture

BOX 1 Factors Linked to Preterm Labor

Demographic and Psychosocial
- Extremes of age (>40 yr, teenagers)
- Lower socioeconomic status
- Tobacco use
- Cocaine abuse
- Prolonged standing (occupation)
- Psychosocial stressors

Reproductive and Gynecologic
- Prior preterm delivery
- Diethylstilbestrol exposure
- Multiple gestations
- Anatomic endometrial cavity anomalies
- Cervical incompetence
- Low pregnancy weight gain
- First-trimester vaginal bleeding
- Placental abruption or previa

Surgical
- Prior reproductive organ surgery
- Prior paraendometrial surgery other than genitourinary (appendectomy)

Infectious
- Urinary tract infections
- Nonuterine infections
- Genital tract infections (bacterial vaginosis)

From Marx JA et al: *Rosen's emergency medicine: concepts and clinical practice,* ed 7, Philadelphia, 2010, Elsevier.

- Urine toxicology screen
- Collect tests for GBS, gonorrhea, and *Chlamydia*
- Perform a wet prep for yeast, bacterial vaginosis, and *Trichomonas*
- Fetal fibronectin swab as described earlier
- Consider PT, PTT, INR, CMP, amylase, and lipase
- Amniocentesis may be performed if an intraamniotic infection is suspected

IMAGING STUDIES

A formal ultrasound is indicated to determine estimated fetal weight, fetal presentation, amniotic fluid volume, placental location and appearance, and cervical length.

The diagnosis of preterm labor is confirmed in the presence or regular contractions if the patient is >3 cm dilated, ≥80% effaced, or <2 cm cervical length by cervical ultrasonography. Diagnosis may also be confirmed if the patient is <3 cm dilated or <80% effaced or 2–3 cm cervical length if FFN is positive or if cervical change is documented over time.

Rx TREATMENT

Patients with premature labor should be delivered promptly when an intraamniotic infection is suspected or when they have cervical dilation >5 cm, a persistently nonreassuring fetal heart rate tracing, or significant vaginal bleeding concerning for placental abruption having maternal or neonatal implications.

NONPHARMACOLOGIC THERAPY

- Smoking cessation.
- Bedrest, activity restriction, and pelvic rest are often recommended by clinicians, but there are insufficient data to support this practice.

ACUTE GENERAL Rx

- Antenatal administration of corticosteroids between 24 wk and 33 6/7 wk gestation is recommended for women at risk of preterm delivery to prevent neonatal respiratory distress syndrome and decrease the incidence of intraventricular hemorrhage and necrotizing enterocolitis. It is also recommended between 34.0 and 36.5 wk gestation if there is no prior steroid exposure.
- Numerous tocolytic agents have been used in an attempt to inhibit contractions (Box 2). Although efficacy is unclear, they can be utilized during an observation period in an effort to prolong gestation for administration and exposure of steroids or to transfer the mother to a facility capable of caring for preterm infants. This, of course, assumes there are no maternal or fetal medical contraindications to use of tocolytic drugs and no indications for rapid delivery. The most commonly used tocolytics are beta-mimetics (terbutaline), magnesium sulfate, calcium channel blockers (nifedipine), or prostaglandin synthetase inhibitors (indomethacin, ketorolac, sulindac). Table E1 summarizes side effect profiles of tocolytic agents.

BOX 2 Commonly Used Tocolytic Agents

Magnesium sulfate
- 4-6 g IV bolus over 30 min
- 2-4 g/hr IV infusion

Terbutaline
- 5-10 mg PO q4-6h
- 0.25-0.5 mg SC q30 min-6 h
- 10-80 μg/min IV

Ritodrine*
- 10 mg PO q2-4 h
- 5-10 mg IM q2-4 h
- 50-350 μg/min IV

Isoxsuprine
- 20 mg PO q4-6 h
- 0.05-0.5 mg/min IV

*Ritodrine is currently discontinued in the U.S. *IV,* Intravenously; *PO,* orally; *SC,* subcutaneously.
From Marx JA et al: *Rosen's emergency medicine: concepts and clinical practice,* ed 7, Philadelphia, 2010, Elsevier.

Routine antibiotic use has failed to show benefit in the absence of a known infection. But all mothers in preterm labor (without a documented negative group B strep culture) should be given antibiotics to prevent neonatal GBS infection.

Intravenous magnesium sulfate has been shown to decrease cerebral palsy in children exposed antenatally with premature labor or premature rupture of the membranes.

PROPHYLACTIC OR CHRONIC Rx

- Patients with a history of prior spontaneous preterm birth may be candidates for prophylactic use of 17 alpha-hydroxyprogesterone caproate between 16 wk and 36 wk gestation.
- Patients with a history of preterm birth and short cervix may also be candidates for prophylactic or rescue cerclage.
- There is no evidence supporting the use of maintenance tocolytic therapy.

REFERRAL

- Women who present in preterm labor should be referred to an obstetrician and transferred to a facility with a neonatal intensive care unit.
- For women who present for prenatal care with a history of preterm delivery, early referral to an obstetrician is also recommended.

TABLE E1 Side Effect Profiles of Tocolytic Agents

	Side Effects		
Agent or Class	**Maternal**	**Fetal or Neonatal**	**Contraindications**
β-adrenergic receptor agonists	Tachycardia and hypotension, tremor (39% vs. 4% with placebo), shortness of breath (15% vs. 1% with placebo), chest discomfort (10% vs. 1% with placebo), pulmonary edema (0.3%), hypokalemia (39% vs. 6% with placebo), hyperglycemia (30% vs. 10% with placebo)	Tachycardia	Tachycardia-sensitive maternal cardiac disease, poorly controlled diabetes mellitus
Magnesium sulfate	Flushing, diaphoresis, nausea, loss of deep-tendon reflexes (at serum levels of 9.6-12 mg/dl), respiratory paralysis (at serum levels of 12-18 mg/dl), cardiac arrest (at serum levels of 24-30 mg/dl); when used with calcium channel blockers, suppression of heart rate, contractility and left ventricular systolic pressure, and neuromuscular blockade	Data conflict with regard to effect on perinatal mortality	Myasthenia gravis
Calcium channel blockers	Dizziness, flushing, hypotension when used with magnesium sulfate, suppression of heart rate, contractility, and left ventricular systolic pressure and neuromuscular blockade; elevation of hepatic aminotransferase levels, reflexive headache		Hypotension, preload-dependent cardiac lesions (e.g., aortic insufficiency)
Cyclo-oxygenase inhibitors	Nausea, esophageal reflux, gastritis, and emesis; platelet dysfunction (rarely of clinical significance in patients without underlying bleeding disorder)	In utero closure of ductus arteriosus (risk associated with use for >48 hr), patent ductus arteriosus in neonate (conflicting data), oligohydramnios (reversible), NEC (conflicting data)	Platelet dysfunction or bleeding disorder, hepatic or renal dysfunction, gastrointestinal or ulcerative disease, asthma (in women with hypersensitivity to aspirin)
Oxytocin receptor antagonists	Hypersensitivity injection-site reactions	For atosiban, an increased rate of fetal or infant death (may be attributable to the lower gestational age of infants in the atosiban group)	None
Nitric oxide donors	Dizziness, flushing, hypotension		Hypotension, preload-dependent cardiac lesions (e.g., aortic insufficiency)

BASIC INFORMATION

DEFINITION

Priapism is the persistent, usually painful erection associated or unassociated with sexual stimulation. There are two major forms: Low-flow (venoocclusive) priapism and high-flow priapism (associated with increased arterial inflow without increased venous outflow resistance).

ICD-10CM CODES

N48.30 Priapism, unspecified
N48.31 Priapism due to trauma
N48.32 Priapism due to disease classified elsewhere
N48.33 Priapism, drug-induced
N48.39 Other priapism

EPIDEMIOLOGY & DEMOGRAPHICS

- Peak incidence is seen from ages 5 to 10 yr and 20 to 50 yr.
- In the younger group, priapism is often associated with sickle cell disease or neoplasm. In the older group it is often caused by pharmacologic agents.
- Low-flow (venoocclusive priapism [type I]) is much more common than high-flow (type II).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- In idiopathic priapism the initial erection is associated with prolonged sexual excitement. Previous transient episodes are frequently reported. The erection involves the corpora cavernosa alone. Detumescence does not occur spontaneously.
- In secondary priapism, sexual excitement need not be involved. Otherwise the clinical picture is the same as in idiopathic priapism.
- Table E1 compares normal erection and priapism.

ETIOLOGY

Idiopathic: Prolonged sexual arousal

- Secondary or associated causes:
  1. Sickle cell disease
  2. Diabetes
  3. Leukemia (especially chronic myelogenous leukemia)
  4. Solid tumor (malignant) penile infiltration
  5. Spinal cord injury
  6. Perineal or penile trauma
  7. Iatrogenic
  8. Total parenteral nutrition, which includes a fat emulsion
  9. Hyperosmolar IV contrast
  10. Spinal or general anesthesia
  11. Anticoagulant therapy
  12. Phenothiazines
  13. Trazodone
  14. Intracorporeal injection therapy for impotence
  15. Phosphodiesterase type 5 inhibitors (e.g., sildenafil [Viagra], tadalafil [Cialis], vardenafil [Levitra])
  16. Box E1 summarizes the various causes of priapism

PATHOPHYSIOLOGY

- Low-flow priapism: Prolonged erection leads to edema of the cavernosal trabeculae, resulting in a sequence of stasis, thrombosis, venous occlusion, fibrosis, scarring, and possibly impotence.
- High-flow priapism: Cavernosal artery rupture leading to an arteriocavernous fistula.

DIAGNOSIS

WORKUP

None if the associated underlying causes are known to be present. Otherwise they should be ruled out. Box E2 summarizes key elements in taking the history in patients with priapism. Low-flow priapism can be distinguished from high-flow priapism by obtaining a corporeal blood gas value. A PO_2 <30 mm Hg, PCO_2 >60 mm Hg, and a pH <7.25 are consistent with low-flow priapism. High-flow priapism can be confirmed by a perineal Doppler ultrasound (Fig. E1) or arteriography (useful to identify arterial-lacunar fistula).

TREATMENT

- Fig. E2 illustrates an algorithm for managing ischemic priapism. An approach to the management of high-flow priapism is shown in Fig. E3.
- Goal: Achieve detumescence with preservation of potency.
- Medical therapies:
  1. Ice packs
  2. Ice water enemas
  3. Hot water enemas
  4. Pressure dressing
  5. Sedatives
  6. Analgesics
  7. Antispasmodic/anticholinergic drugs
  8. Estrogens
  9. Anticoagulants
  10. Procaine
  11. Amyl nitrite
  12. Local or general anesthesia
  13. Ketamine (1 mg/lb)
- In the patient with sickle cell disease: Intravenous hydration, alkalinization, transfusion or exchange transfusion, oxygen.
- Corporeal irrigation with normal saline may be used for low-flow priapism. The midshaft of the penis can be injected with a small-gauge butterfly needle and irrigated with 10 to 20 ml of normal saline, followed by an intracorporeal injection of an alpha-adrenergic agonist every 5 min until detumescence. Commonly used intracavernous vasoconstrictor agents are epinephrine (10 to 20 mcg), phenylephrine (250 to 500 mcg), and ephedrine (50 to 100 mg). It is mandatory to monitor the patient's blood pressure and pulse when using alpha-adrenergic agonists.
- Surgery:
  1. Cavernospongiosum shunt
  2. Glans-cavernosum shunt
  3. Cavernosaphenous shunt
  4. In the less common situation of high-flow priapism (diagnosed by the finding of bright red arterial blood on aspiration), arterial embolization or surgical ligation is recommended.

PROGNOSIS

Impotence is associated with the duration of priapism, with 36 hr being an important threshold.

REFERRAL

To urologist

Trazodone, bupropion, fluoxetine, sertraline, lithium, clozapine, risperidone, olanzapine, chlorpromazine, thioridazine, phenothiazines

Antihypertensives
Hydralazine, guanethidine, propranolol

Attention-Deficit/Hyperactivity Disorder Agents
Methylphenidates (Concerta, Daytrana, Focalin, Metadate, Methylin, Quillivant, Ritalin)
Atomoxetine (Strattera)

Recreational Drugs
Alcohol, cocaine (intranasal and topical), crack cocaine, marijuana

Genitourinary Conditions
Straddle injury, coital injury, pelvic trauma, kick to penis or perineum, arteriovenous or arteriocavernous bypass surgery, urinary retention

Hematologic Dyscrasias
Sickle cell disease, thalassemia, granulocytic leukemia, myeloid leukemia, lymphocytic leukemia, multiple myeloma, hemoglobin Olmsted variant, fat emboli associated with hyperalimentation, hemodialysis, glucose-6-phosphate dehydrogenase deficiency

Hormones
Gonadotropin-releasing hormone, testosterone

Infectious (Toxin-Mediated) Causes
Scorpion sting, spider bite, rabies, malaria

Metabolic Conditions
Amyloidosis, Fabry disease, gout

Neoplastic Causes (Metastatic or Regional Infiltration)
Prostate, urethra, testis, bladder, rectum, lung, kidney

Neurogenic Conditions
Syphilis, spinal cord injury, cauda equina compression, autonomic neuropathy, lumbar disk herniation, spinal stenosis, cerebral vascular accident, brain tumor, spinal anesthesia, cauda equina syndrome

Vasoactive Erectile Agents
Papaverine, phentolamine, prostaglandin E_1, oral phosphodiesterase type 5 inhibitors, combination intracavernous therapy

Modified and updated from Lue TF: Physiology of penile erection and pathophysiology of erectile dysfunction and priapism. In Walsh PC et al (eds): *Campbell's urology,* Philadelphia, 2002, Saunders.

BOX E2 Elements in Taking the History of Priapism

Duration of erection
Presence of pain
Previous episodes of priapism and method of treatment
Baseline erectile function
Use of any erectogenic therapies (both prescription and nutritional supplements)
Medications and recreational drugs
Sickle cell disease, hemoglobinopathies, hypercoagulable states
Trauma to the pelvis, perineum, or penis

From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.

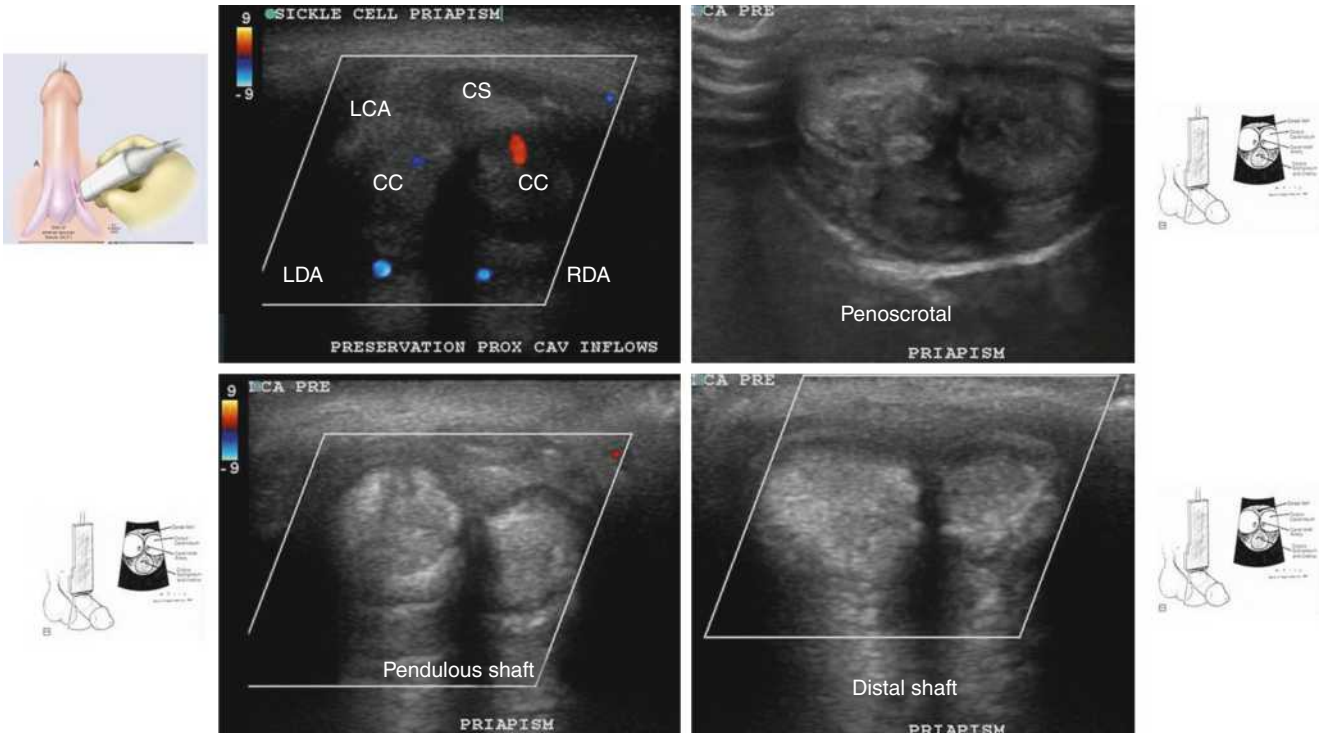

FIG. E1 This 21-year-old Nigerian man had erectile dysfunction after recurrent episodes of sickle cell ischemic priapism. A, Transperineal imaging with color Doppler shows preservation of cavernous arterial inflow at the origin in the corpora cavernosa. **B–D,** Increasing echogenicity on gray-scale ultrasonography of the penile shaft: Penoscrotal, pendulous shaft, and distal shaft. These findings are the result of recurring ischemic priapism, which leaves the patient with distal corporal fibrosis. *CC,* Corpora cavernosa; *CS,* corpus spongiosum; *LCA,* left cavernous artery; *LDA,* left dorsal artery; *RDA,* right dorsal artery. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

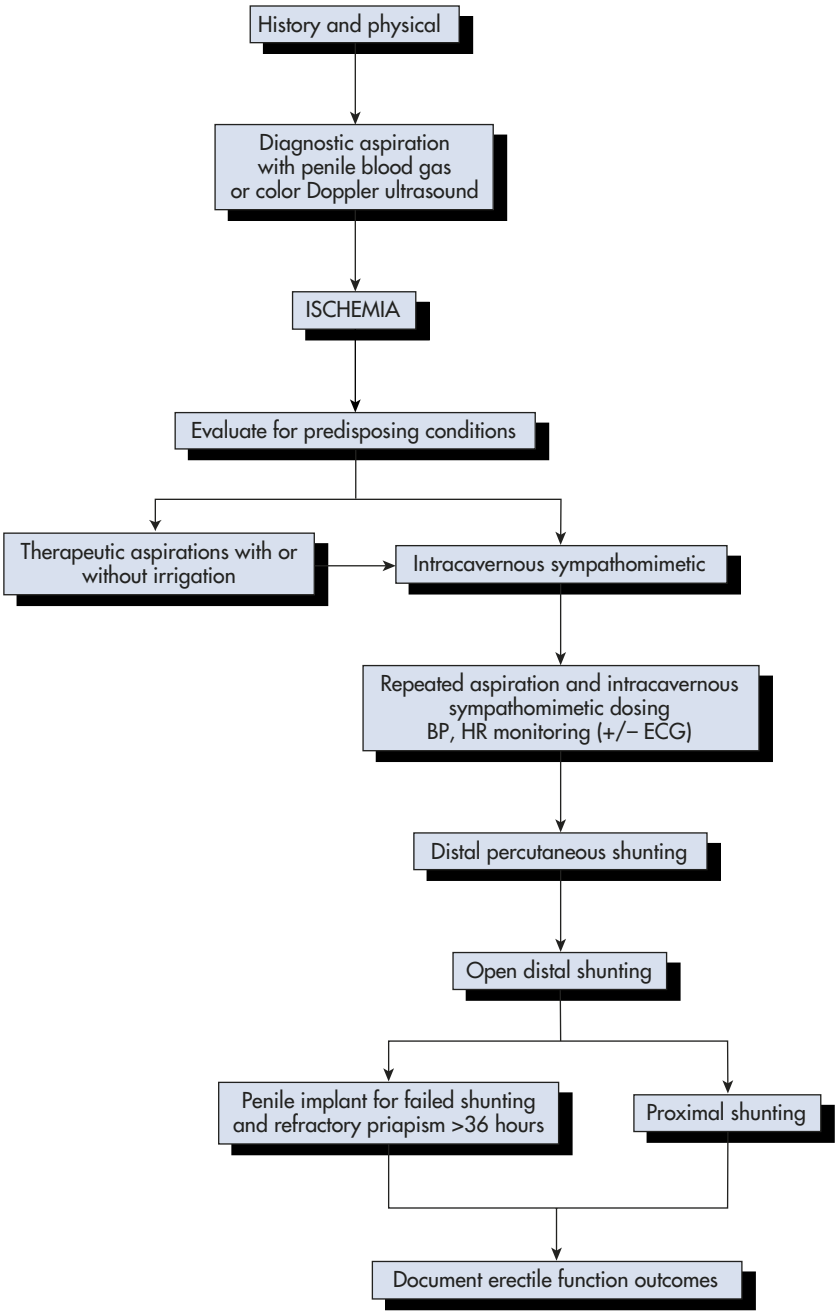

FIG. E2 Algorithm for managing ischemic priapism. *BP,* Blood pressure; *ECG,* electrocardiogram; *HR,* heart rate. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

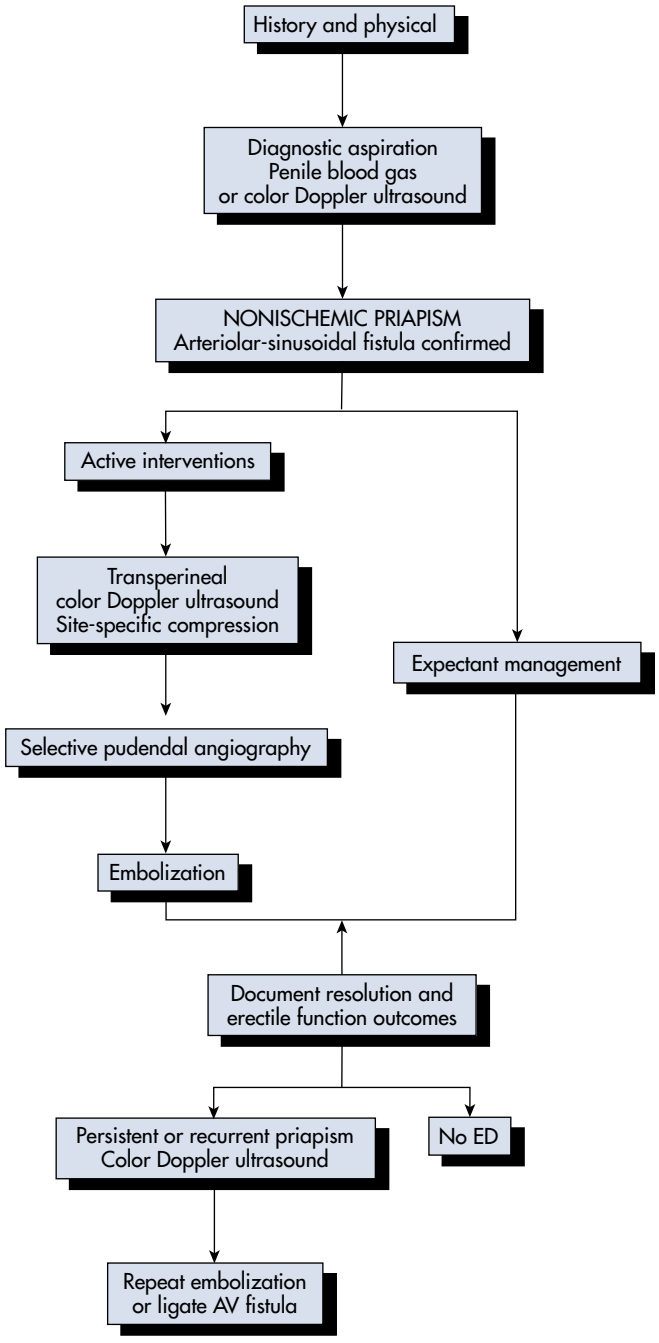

FIG. E3 Algorithm for managing high-flow priapism. *AV,* Arteriovenous; *ED,* erectile dysfunction. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

- Primary angiitis of the central nervous system (PACNS) is the preferred name for vasculitis that is confined to the CNS.
- CNS vasculitis is considered secondary when it occurs in the context of a systemic inflammatory disease, such as a systemic vasculitis or systemic lupus erythematosus (SLE), or an infectious process such as varicella zoster virus.
- PACNS predominantly affects small- and medium-sized arteries of the brain parenchyma, spinal cord, and leptomeninges, resulting in symptoms and signs of CNS dysfunction.
- It is defined by inflammation of the cerebral vasculature without angiitis in other organs.

SYNONYMS

PACNS
CNS vasculitis

ICD-10CM CODE
I67.7 Cerebral endarteritis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: PACNS is a rare disease. A retrospective analysis of 101 patients with PACNS reported an annual incidence rate of 2.4 cases per 1,000,000 person-yr.
PREDOMINANT SEX: There is a 2:1 male predominance among reported cases.
PREDOMINANT AGE: The median age at diagnosis is 50 yr, although PACNS can occur at almost every age.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- PACNS is characterized by a long prodromal period, with few patients presenting acutely.
- The vasculitis can affect any part of the CNS, causing the clinical manifestations to be highly variable and nonspecific.
- Headache is the most commonly reported symptom, usually subacute and insidious, in contrast to the sudden-onset thunderclap headache that is observed with reversible cerebral vasoconstriction syndromes (RCVS).
- Other symptoms include cognitive impairment, stroke, and transient ischemic attack.
- Patients with PACNS who develop strokes usually present with more than a single stroke in different anatomic territories.
- Other, less common symptoms may appear, including cranial neuropathies, ataxia, and seizure.
- Signs and symptoms suggestive of systemic vasculitis, such as peripheral neuropathy, fever, weight loss, or rash, are usually lacking.
- Spinal cord involvement occurs alone or coincides with parenchymal brain involvement.
- Angiitis affecting the spinal cord usually presents as a myelopathy, with pain, motor weakness, and sensory findings.
- Symptoms and signs of untreated PACNS progress over the course of months.

ETIOLOGY

- The cause of PACNS is unknown.
- Several potential etiologic agents or mechanisms have been proposed, but understanding of the cause of PACNS remains highly speculative.
- Various infectious agents have been proposed as etiologic factors, such as varicella zoster virus, West Nile virus, *Mycoplasma gallisepticum*, and HIV.
- Cerebral amyloid angiopathy and PACNS have been described together in some patients, and associations between amyloid depositions have also been proposed as a trigger.
- Although the cause of PACNS is unknown, inflammation of the CNS causes the vessels to become narrowed, occluded, and thrombosed, resulting in tissue ischemia and necrosis of the territories of the involved vessels.
- PACNS is more likely to affect blood vessels in the cerebral cortex and leptomeninges than subcortical regions.
- Blood vessels supplying cranial nerves may also be involved.

DIAGNOSIS

- The diagnosis of PACNS is based upon a constellation of symptoms and signs in the `setting of supportive studies and the exclusion of alternative diagnoses
- The diagnosis can usually be made when all of the following are present:
  1. An acquired otherwise unexplained neurologic deficit
  2. Evidence of either classic angiographic or histopathologic features of angiitis within the CNS (Table E1)
  3. No evidence of systemic vasculitis or any other condition that could elicit the angiographic or pathologic findings

DIFFERENTIAL DIAGNOSIS

PACNS can be mimicked closely in both its clinical presentation and radiologic manifestations by a number of other disorders (Box E1). The most frequent mimic of PACNS is a group of disorders known collectively as the reversible cerebral vasoconstriction syndromes (RCVS) (Box E2).

LABORATORY TESTS

- Laboratory testing and serological assays (Box E3) are used primarily to exclude other etiologies of CNS dysfunction.
- Analysis of the cerebrospinal fluid (CSF) is a crucial part of the evaluation of patients with potential PACNS and should be performed in all patents unless there are contraindications.
- The CSF is abnormal in 80% to 90% of patients with pathologically documented disease.

TABLE E1 Demographic Characteristics, Clinical Features, and Imaging Studies Distinguishing Primary Angiitis of the Central Nervous System from Reversible Cerebral Vasoconstriction Syndrome

Feature	PACNS	RCVS
	Demographics	
Age at onset (yr)	40-50	20-40
Gender predilection	Men	Women
Clinical features	Variable	Cephalgia Catastrophic stroke or edema
Onset of symptoms	Insidious	Acute or subacute
Provocative factors	None	Vasoactive medication Eclampsia or postpartum status Migraine
Headache	Progressive	Thunderclap
Stroke, onset	During the course of illness	Early, a few days after initial normal imaging
Course	Progressive	Uniphasic Rapid dynamic nature
Diagnosis		
CSF	Abnormal	Normal
High-resolution MRI of the vessel wall	Arterial wall enhancement	Lack of contrast enhancement
Treatment	Glucocorticoids or immunosuppressives	Calcium channel blockers or nimodipine Magnesium
Resolution at follow-up angiography	Months	Within 3 months

CSF, Cerebrospinal fluid; *MRI,* magnetic resonance imaging; *PACNS,* primary angiitis of the central nervous system; *RCVS,* reversible cerebral vasoconstriction syndrome.

BOX E1 Clinical Syndromes of Cerebral Vasculitis

I. Primary CNS vasculitis or PACNS
   1. Granulomatous angiitis of the central nervous system
II. Secondary CNS vasculitis
   1. Systemic vasculitis
      a. Behçet disease
      b. Necrotizing arteritis of the polyarteritis type (PAN)
      c. Systemic granulomatous vasculitis/ANCA-associated vasculitis (GPA, EGPA)
      d. Giant cell arteritis
      e. Hypersensitivity vasculitis and cryoglobulinemic vasculitis
      f. Kawasaki disease
   2. Systemic rheumatic diseases
      a. Systemic lupus erythematosus
      b. Sjögren syndrome
      c. Rheumatoid arthritis
      d. Mixed connective tissue disease or overlap syndrome
      e. Scleroderma
      f. Sarcoidosis
      g. Inflammatory bowel disease
   3. Infection-associated cerebral vasculitis
      a. Virus (varicella-zoster virus, West Nile virus, cytomegalovirus, hepatitis B and C viruses)
      b. Retroviral infection/HIV-1
      c. Spirochete *(Treponema pallidum, Borrelia burgdorferi)*
      d. Fungi (*Aspergillus, Coccidioides, Histoplasma* spp.)
      e. *Bartonella* spp.
      f. *Rickettsia* spp.
      g. Bacterial meningitis
      h. *Mycoplasma* spp.
      i. *Mycobacterium tuberculosis*
      j. Protozoal, amebiosis, cysticercosis
   4. Cerebral vasculitis associated with amyloidosis, amyloid angiitis
   5. Cerebral vasculitis associated with paraneoplastic disorders, paraneoplastic angiitis

ANCA, Antineutrophil cytoplasmic antibody; *CNS*, central nervous system; *EGPA,* eosinophilic granulomatosis with polyangiitis; *GPA,* granulomatosis with polyangiitis; *HIV,* human immunodeficiency virus; *PACNS,* primary angiitis of the nervous system.
From Hochberg MC et al: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BOX E2 Noninflammatory Vasculopathic Disorders that Mimic Primary Angiitis of the Central Nervous System

Reversible Cerebral Vasoconstriction Syndromes
Intracranial atherosclerosis
Cerebral embolism
Hypercoagulable state
Intracranial vertebral artery dissection
Neurofibromatosis
Fibromuscular dysplasia
Susac syndrome
Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy
Moyamoya disease
Acute multifocal placoid pigment epitheliopathy
Mitochondrial encephalopathy, lactic acidosis, and strokelike illness (MELAS)
Progressive multifocal leukoencephalopathy
Reversible posterior leukoencephalopathy syndrome
Demyelinating syndrome

From Hochberg MC et al: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BOX E3 Laboratory Evaluation for Suspected Primary Angiitis of the Central Nervous System

General Studies
Complete blood count
Complete metabolic panel and hepatic function test
Erythrocyte sedimentation rate
C-reactive protein
Lipid panel
Urinalysis and urine microalbumin
Urine toxicology screen
Prothrombin and thromboplastin time
Proteins S and C
Serum and urine protein electrophoresis and serum immunoglobulin electrophoresis
Quantitative immunoglobulin
Acute hepatitis panel, B and C virus
HIV
Serology panel
Rheumatoid factor
Antinuclear antibody
Antibodies to Ro/SSA, La/SSB, Sm, and RNP antigens
Anticardiolipin antibody and lupus anticoagulant
Serum complement level: C2, C3, C4, and CH^{50}
Antibody to double-stranded DNA
Antineutrophil cytoplasmic antibody
Angiotensin-converting enzyme
Lyme titer (ELISA and Western blot)
Serum cryoglobulins
Treponema pallidum, rapid plasma antigen, and fluorescent treponemal antigen
Cerebrospinal fluid studies
Protein
Glucose
Cell count
IgG level and index
Oligoclonal bands
Venereal Disease Research Laboratory (VDRL)
Viral antibodies and antigens and polymerase chain reaction for West Nile virus, cytomegalovirus, herpes simplex and herpes zoster, and HIV
Lyme titer
ANCA titer
ACE level
India ink, Gram stain, and routine cultures, including acid-fast bacillus stain

ACE, Angiotensin-converting enzyme; *ANCA,* antineutrophil cytoplasmic antibody; *CH^{50},* 50% hemolyzing dose of complement; *ELISA,* enzyme-linked immunosorbent assay; *HIV,* human immunodeficiency virus; *RNP,* ribonucleoprotein.
From Hochberg MC et al: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

- CSF findings are nonspecific but most commonly include an elevated CSF protein and a modest lymphocytic pleocytosis.
- Fig. E1 describes an algorithmic approach to the diagnosis of PACNS.

Small vessel PACNS may have normal cerebral angiography. However, PACNS is unlikely in the context of normal brain MRI and normal cerebrospinal fluid studies.

IMAGING STUDIES

- Various neuroimaging modalities can be used to assess for both parenchymal and vascular abnormalities in the evaluation of suspected PACNS.
- Magnetic resonance imaging (MRI) should be performed in all patients.
- The selection of additional neuroimaging modalities depends on the initial MRI findings and individual patient characteristics.
- Conventional angiography (Fig. E2) remains an important part of the diagnostic testing for suspected PACNS.
- Angiography can detect segmental narrowing in multiple vessels that are typical of, though

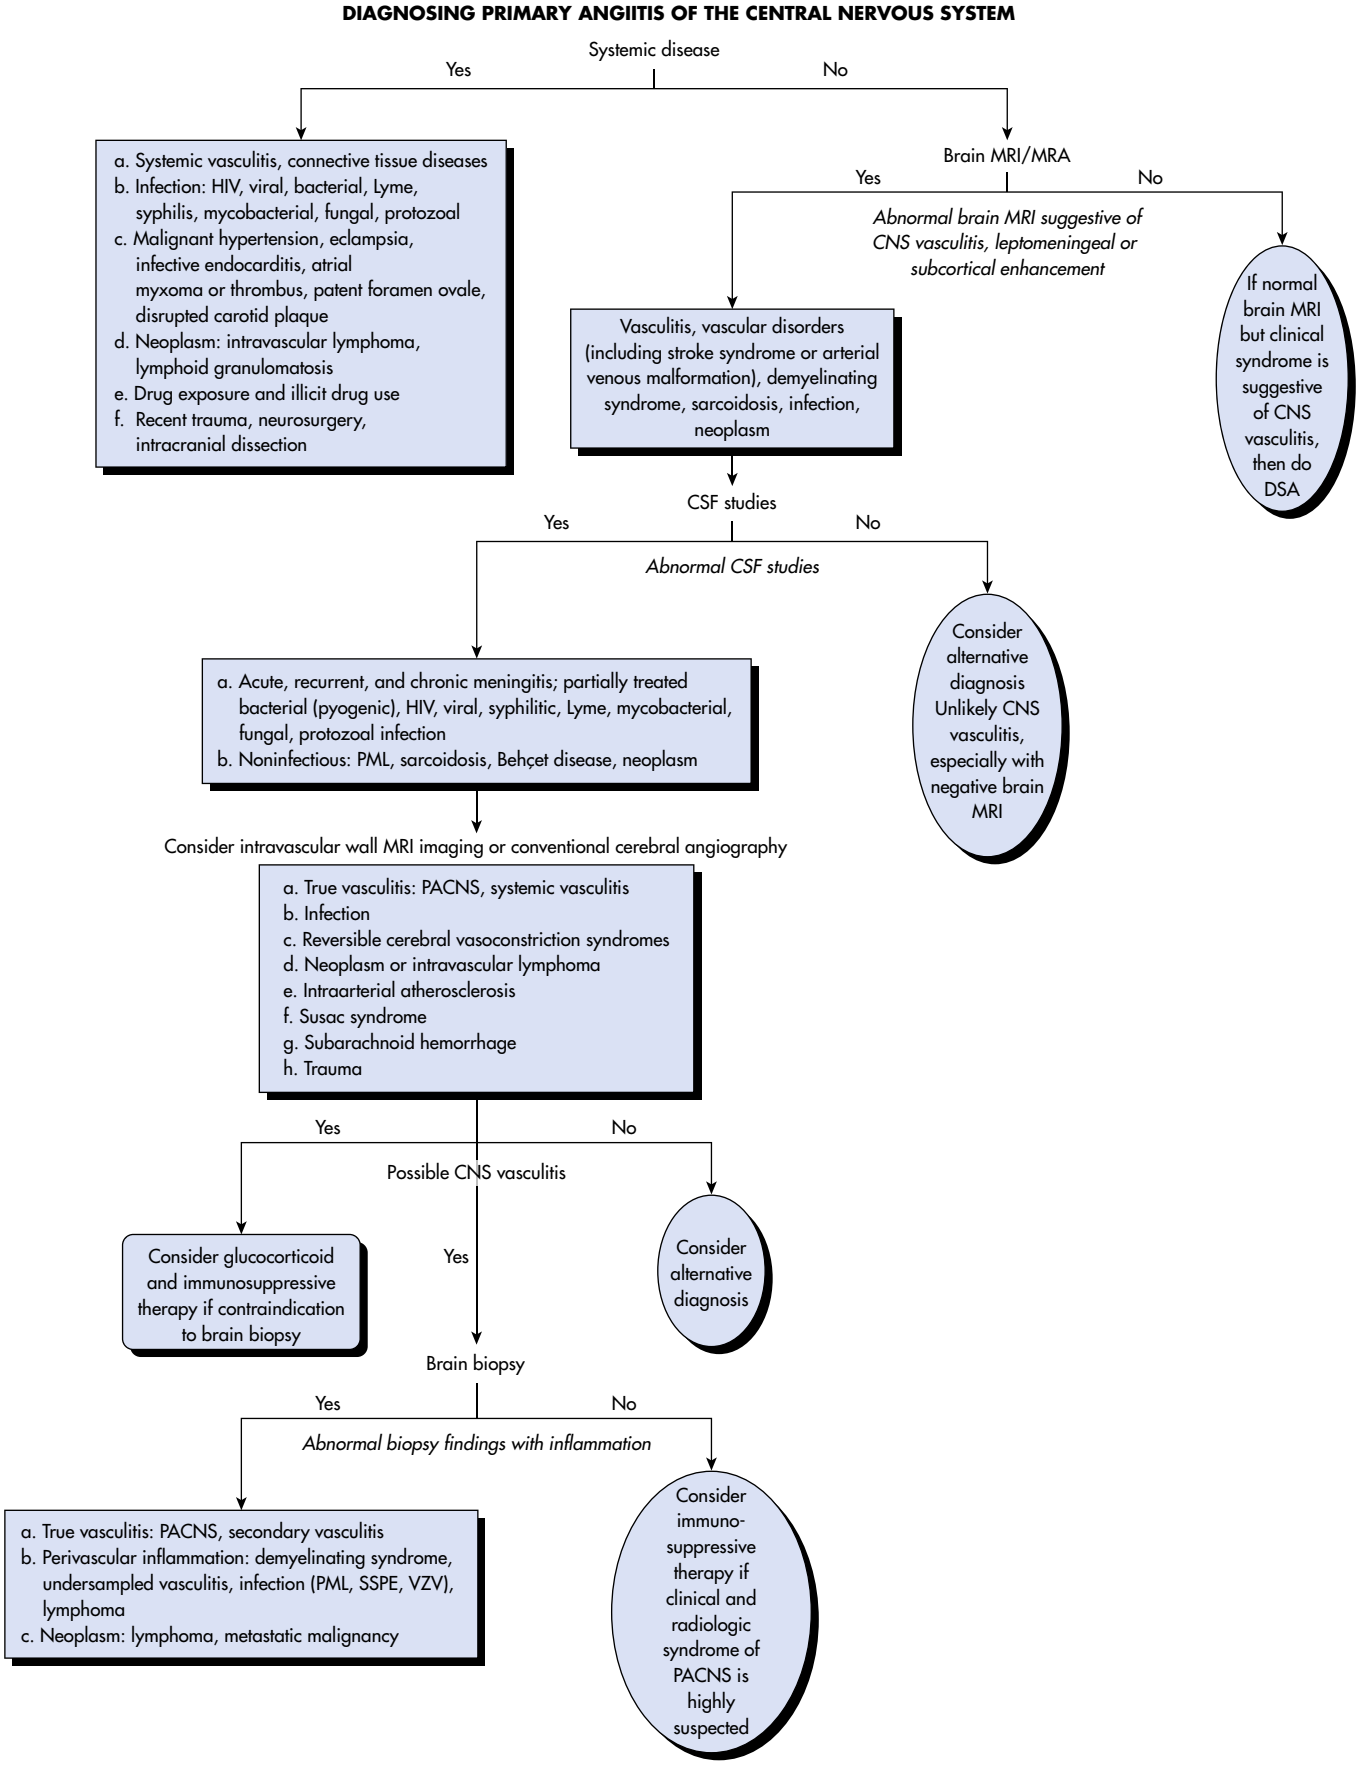

FIG. E1 Algorithmic approach to the diagnosis of primary angiitis of the central nervous system (PACNS). PACNS presents with a clinical syndrome of unclear etiology with altered mental status, headache, and seizure. *CSF,* Cerebrospinal fluid; *CNS,* central nervous system; *DSA,* digital subtraction angiography; *HIV,* human immunodeficiency virus; *MRA,* magnetic resonance angiography; *MRI,* brain magnetic resonance imaging; *PML,* progressive multifocal leukoencephalopathy; *SSPE,* subacute sclerosing panencephalitis; *VZV,* varicella-zoster virus. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

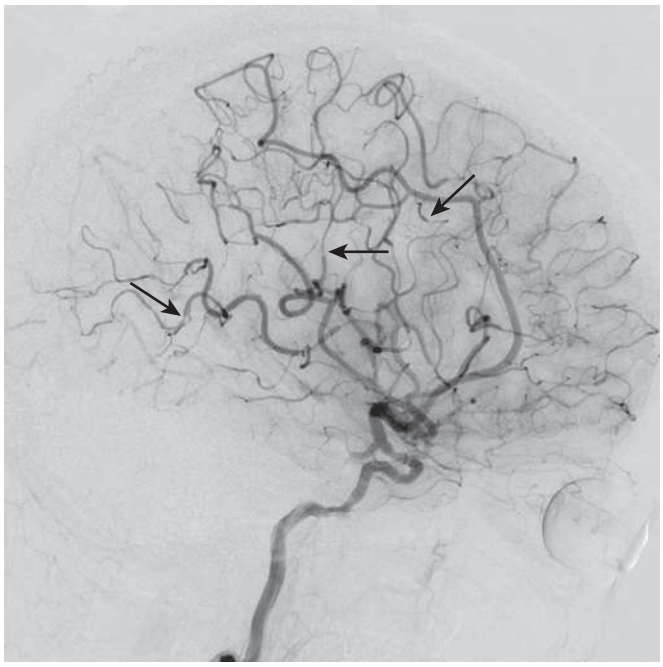

FIG. E2 Cerebral angiography of primary angiitis of the central nervous system (PACNS). Diffuse irregularity and severe multifocal narrowing in the distribution of large, intermediate, and small arteries. Typical PACNS features include beading, segmental narrowing, and dilation *(arrows),* aneurysmal dilatation, circumferential or eccentric vessel irregularities, and multiple occlusions with sharp cutoffs. (From Hochberg MC et al: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

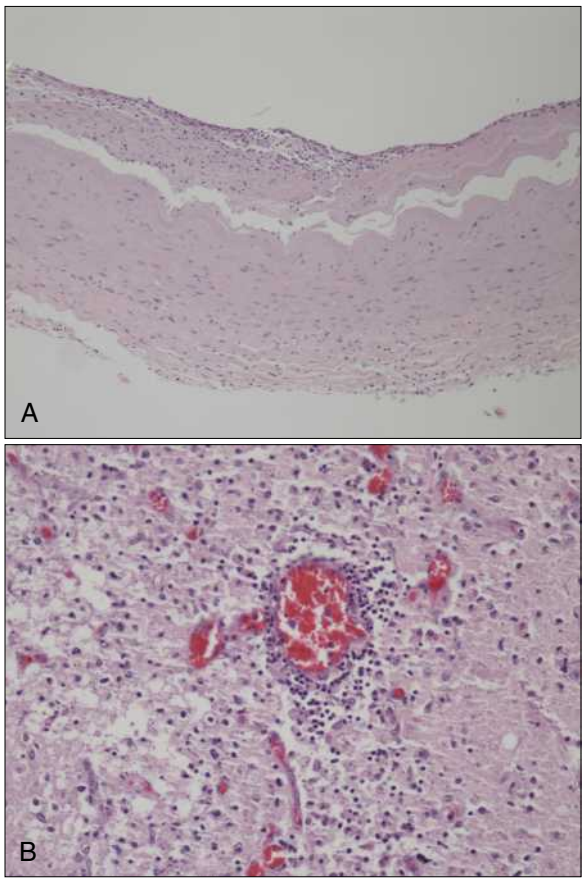

FIG. E3 Brain biopsy findings of granulomatous vasculitis. A, A large artery inflammatory vasculopathy with fibroblastic and smooth muscle proliferation accompanied by mononuclear cell infiltrate in the arterial wall (intima, media, and adventitia). **B,** Granulomatous vasculitis with a mixture of epithelioid cells, plasma cells, macrophages, and scattered granulomas (hematoxylin-eosin staining). (From Hochberg MC et al: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

not pathognomonic for, PACNS, and help further rule out alternative diagnoses such as atherosclerosis, moyamoya, and dissection. These tests may also be helpful in selecting a location for brain biopsy if needed.

- A brain biopsy should be performed in most patients with suspected PACNS. A biopsy will help histologically identify PACNS (Fig. E3) as well as exclude other lesions or vasculitis mimics, particularly infection or malignancy.

Rx TREATMENT

ACUTE GENERAL Rx

- PACNS should be treated with a combination of glucocorticoids and cyclophosphamide (Grade 2C).
- Treatment of atypical PACNS should be individualized according to the severity and the extent of the neurologic deficit.
- The response to treatment is monitored by periodic reassessment of symptoms, neurologic findings, and neuroimaging abnormalities.
- It is important to differentiate between disease damage and disease progression. Neurologic deficits due to cerebral or cerebellar infarction may resolve slowly or not at all.
- For some patients, a response to treatment may only be indicated by symptomatic improvement (e.g., resolution of headache) but not the resolution of magnetic resonance (MR) lesions.
- A lack of new lesions on MRI is a more reliable way to assess for progression of the disease.
- A follow-up MR should be obtained 4 to 6 wk after beginning treatment, then every 3 to 6 mo throughout therapy, and subsequently according to the evolution of the disease.

CHRONIC Rx

We recommend the use of measures to prevent osteoporosis and *Pneumocystis* infections during the treatment of PACNS (Grade 1A).

DISPOSITION

Usually inpatient due to severe disease presentation

REFERRAL

Rheumatology, neurology, infectious diseases

! PEARLS & CONSIDERATIONS

- PACNS predominantly affects small- and medium-sized arteries of the brain parenchyma, spinal cord, and leptomeninges, resulting in symptoms and signs of CNS dysfunction.
- The most frequent mimic of PACNS is a group of disorders known collectively as the reversible cerebral vasoconstriction syndromes (RCVS).
- The diagnosis of PACNS is based upon a constellation of symptoms and signs in the setting of supportive studies and the exclusion of alternative diagnoses.
- CSF findings are nonspecific but most commonly include an elevated CSF protein and a modest lymphocytic pleocytosis.

- PACNS should be treated with a combination of glucocorticoids and cyclophosphamide (Grade 2C).

BASIC INFORMATION

DEFINITION

Primary biliary cholangitis (PBC), previously known as primary biliary cirrhosis is a chronic, variably progressive cholestatic liver disease most often affecting middle-aged women and characterized by autoimmune destruction of intralobular bile ducts leading to portal inflammation, hepatic cell necrosis, fibrosis, cirrhosis and, ultimately, liver failure.

SYNONYMS

PBC
Primary biliary cirrhosis
Biliary cirrhosis
Nonsuppurative destructive cholangitis
Autoimmune cholangiopathy (AIC)

ICD-10CM CODE
K74.3 Primary biliary cholangitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Annual incidence rates range from 3.3 to 58 cases per million.
- PBC accounts for up to 2% of deaths from cirrhosis worldwide.

PREVALENCE: Prevalence is greatest in North America and Northern Europe and varies tremendously by time and geographic areas, ranging globally from 2.7 to 492 cases per million. Disease burden seems to be increasing, which may be a result of better detection rather than true rise in disease incidence.

PREDOMINANT SEX: Female:male ratio of 9:1

PREDOMINANT AGE: Onset typically occurs between the ages of 30 and 65 yr and is uncommon before age 25 yr.

PREDOMINANT RACE: Most often described in Caucasians but PBC affects all races.

GENETICS:

- Pathogenesis is unknown, but it is thought to be in the setting of environmental influences and genetic predisposition.
- There are no clearly identified genetic factors associated with PBC; however, there is a clear familial occurrence. Prevalence among familial clustering of PBC is approximately 3% to 9% in the U.S., Brazil, Japan, and Europe. The concordance rate among monozygotic twins is 63%.
- Up to 73% of patients with PBC have at least one other extrahepatic autoimmune disorder such as thyroiditis, Sjögren syndrome, rheumatoid arthritis, cutaneous scleroderma (which can include CREST syndrome), systemic lupus erythematosus, pernicious anemia, celiac disease, autoimmune thrombocytopenia purpura, autoimmune diabetes mellitus, and/or other autoimmune diseases.
- A variant form of PBC exists as an overlap syndrome with autoimmune hepatitis (AIH).
- PBC is closely associated with a greater risk of hepatocellular carcinoma as well as an overall greater risk of cancer.

ETIOLOGY

- Although the cause of PBC remains unknown, it is believed to require both a genetic susceptibility as well as an environmental trigger ultimately leading to the modification of mitochondrial proteins triggering a persistent T lymphocyte–mediated attack on intralobular bile ducts.
- PBC is associated most strongly with HLA alleles DRA, DRB1, DPB1, DQB1, BTNL2 and c6orf10. PBC is also associated with ORMDL3, CD80, STAT1/STAT4, IL12A, NF-κB, and RPL3/SYNGR1. However, there is variation across ethnic groups.
- Possible environmental triggers include infectious agents, cigarette smoking, environmental pollutants, radiation, urinary tract infections, reproductive hormone replacement, prior pregnancy, toxic waste sites (particularly exposure to halogenated hydrocarbons), electrophilic drugs, and xenobiotics found in food additives and cosmetics.
- The enzyme complex subunit PDC-E2 is an autoantigen that plays a major role in the early pathogenesis of PBC. Patients with PBC have a tenfold increased concentration of PDC-E2-specific cytotoxic $CD8^+$ lymphocytes in their livers compared to their blood, and antimitochondrial antibodies (AMAs), which are the serologic hallmark of this disease, react to the PDC-E2 subunit leading to a strong inflammatory response. In addition, biliary epithelial cells handle PDC-E2 in a unique way that exposes them to immune-mediated attack. Future therapies may be specific immunomodulation directed at these peptides.
- In addition, secondary damage to hepatocytes results from the chronic accumulation of bile acids.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical stages:

- Asymptomatic
- Symptomatic
- Cirrhotic
- Hepatic failure

Symptoms:

- 50% to 65% of patients may be asymptomatic; 50% of patients develop symptoms in 5 yr, 80% in 10 yr, and 95% in 20 yr.
- Fatigue (20% to 85% of patients) and pruritus (40% to 80% of patients) are the usual presenting symptoms and are independent of disease severity.
- Fatigue can be chronic and correlate with daytime somnolence and autonomic dysfunction.
- Pruritus is worse at night, with constricting, coarse garments, and in association with dry skin and hot, humid weather. The cause is unknown but elevated histamine, bile salt concentration, endogenous opioids, lysophosphatidic acid, and female steroid hormones and their metabolites have been discussed as potential causes. Pruritus may first occur during pregnancy but is distinguished from pruritus of pregnancy because it persists into the postpartum period and beyond.
- Symptoms include jaundice (10% to 60%), unexplained right upper quadrant pain (10%), manifestations of portal hypertension, dyslipidemia (76% to 96%), xanthomas (15% to 50%), osteoporosis (20% to 44%), Sjögren syndrome (4% to 73%), rheumatoid arthritis (2% to 6%), systemic lupus erythematosus (up to 4%), celiac disease (up to 6%), and thyroid disorders (6% to 24%) with the most common being Hashimoto thyroiditis.
- Other symptoms can include steatorrhea, fat-soluble vitamin deficiencies, and anemia.

Physical examination:

- Variable: Findings depend on stage of disease at time of presentation; patients at the early stage may be completely unaffected.
- Excoriations may be present due to extensive scratching from pruritus and can be severe enough to cause bleeding.
- Hepatomegaly and splenomegaly can worsen with disease progression.
- Xanthomas and jaundice generally appear in advanced disease. Kayser-Fleischer rings are rare and result from copper retention. Hyperpigmentation of the skin due to melanin deposition may also occur.
- Late physical findings mirror those of cirrhosis: spider nevi, caput medusae, temporal and proximal limb wasting, ascites, palmar erythema, digital clubbing, gynecomastia, and edema.

DIAGNOSIS

The diagnosis of PBC can be established when two of the following three criteria are met.

- Positive serum AMA, titer >1:40 or PBC-specific anti-nuclear antibody reactivity
- Biochemical evidence of cholestasis (mainly alkaline phosphatase elevation [ALP] $\geq$ 1.5 times the upper limit of normal [ULN])
- Characteristic liver histology demonstrating nonsuppurative destruction of small to medium-sized interlobular biliary ducts

DIFFERENTIAL DIAGNOSIS

- Drug-induced cholestasis (common medications: phenothiazines, anabolic steroids, some antibiotics as TMP-SMX, oxacillin, and ampicillin)
- PBC-AIH overlap syndrome; reported in 2% to 20% of patients initially diagnosed with PBC. Transition from stable PBC to AIH and vice versa also seen
- Other etiologies of chronic liver disease and cirrhosis, such as alcoholic cirrhosis, chronic viral hepatitis, primary sclerosing cholangitis, AIH, sarcoidosis, hepatic amyloidosis, chemical/toxin-induced cirrhosis, other hereditary or familial disorders (e.g., cystic fibrosis, α-1-antitrypsin deficiency)
- Biliary obstruction
- Secondary biliary cirrhosis or secondary sclerosing cholangitis

WORKUP

History, physical examination, laboratory evaluation, liver biopsy

LABORATORY TESTS

- AMAs found in 90% to 95% of patients with PBC and are 98% specific.
- Antinuclear antibodies (ANAs) and AMAs found in 53% of patients. In approximately 5% to 10% of patients, AMAs are absent (AMA-negative PBC). Nearly all patients have ANA or AMAs, or both.
- Cholestatic pattern of liver biochemical markers; markedly increased ALP (of hepatic origin). ALP levels along with bilirubin levels correlate with the risk of liver transplantation or death.
- γ-Glutamyl transpeptidase is increased (indicate biliary origin of ALP).
- Serum IgM levels are increased (lower in AMA-negative PBC).
- Bilirubin level is normal early on and increases with disease progression (direct and indirect). Increased serum bilirubin level is a poor prognostic indicator.
- Aminotransferase level may be normal and, if increased, is rarely more than 5 x ULN.
- Markedly increased serum lipids in more than 50% of patients is largely due to increased lipoprotein X (LpX). Total cholesterol may surpass 1000 mg/dl (with increased xanthomas rather than xanthelasmas). In the early stages of PBC, patients can have relatively higher HDL in comparison to LDL and VLDL. This rise in HDL might explain the lack of increased risk for cardiovascular disease. However, cardiovascular risk may still exist due to other risk factors (e.g., family history and metabolic syndrome).
- Percutaneous liver biopsy confirms or rules out the diagnosis, allows staging, but is not essential to make the diagnosis or to initiate medical therapy in patients with typical liver chemistry and positive AMA test.
- Histology is not uniform, so histologic stage is based on the most advanced lesion present.
  1. Stage I: Nonsuppurative cholangitis indicated by lymphocytic infiltration of small bile ducts with or without epithelioid granulomas or plasma cells, limited to portal areas
  2. Stage II: Extension of inflammatory cells to periportal parenchyma, ductular proliferation
  3. Stage III: Bridging necrosis or fibrous septa linking portal triads
  4. Stage IV: Frank cirrhosis with regenerative nodules

IMAGING STUDIES

If history, physical examination, blood tests, and liver biopsy are all consistent with PBC neither imaging nor cholangiography is necessary (Fig. E1).

PROGNOSIS

- Median survival is 7.5 to 16 yr in untreated patients but is getting longer with earlier diagnosis and initiation of treatment. Table 1 summarizes time course of histologic progression to a higher stage in patients with PBC.
- 80% of patients progress one stage within 3 yr, and 31% of patients progress from stage I to stage IV within 4 yr.
- Neither presence nor total titer level of AMAs predicts survival, disease progression, or response to therapy.
- Prognostic laboratory measures: Serum bilirubin is the best predictor of survival and the most heavily weighted factor in prognostic models. Box 1 summarizes independent predictors of survival in patients with PBC.
- Response to ursodeoxycholic acid (UDCA) therapy can be prognostic, with approximately 40% of patients failing to respond. There are multiple biochemical response criteria that, if met after 1 yr of treatment with UDCA, are associated with improved clinical outcomes. Three of these criteria are Barcelona (decrease in ALP level of at least 40% or to the reference range), Paris I (ALP <3 x ULN, AST <2 x ULN and bilirubin within normal limits), and Paris II (ALP <1.5 x ULN, ALT <1.5 x ULN and bilirubin within normal limits). Similarly, the Mayo Risk score, a predictor of short-term survival probability in non-transplanted patients (www.mayoclinic.org/medical-professionals/transplant-medicine/calculators/the-updated-natural-history-model-for-primary-biliary-cirrhosis/itt-20434724), can also reliably predict life expectancy when calculated after 6 mo of UDCA therapy.

Poorer prognosis is associated with jaundice, advanced histologic stage, elevated bilirubin or ALP, low albumin, hepatocellular carcinoma, non-response to UDCA, and esophageal varices.

TABLE 1 Time Course of Histologic Progression to a Higher Stage in Patients with PBC

Histologic Progression*	Initial Histologic Stage		
	1	2	3
1 yr	41	43	35
2 yr	62	62	50

*Percent of patients in whom the histologic stage increases at 1 yr and 2 yr.

Rx TREATMENT

- Treatment is according to the clinical stage of the disease.
- Asymptomatic stage:
  - Follow liver function tests every 3 mo.
  - Once ALP is elevated up to 1.5 x ULN, begin UDCA at 13 to 15 mg/kg/day in two to four divided doses regardless of histologic stage.
    1. Side effects may include headaches, dizziness, diarrhea or constipation, dyspepsia, nausea, weight gain, back pain, and upper respiratory infections.
    2. Watch for interactions with fibric acid derivatives, bile acid sequestrants, estrogen derivatives, as well as aluminum hydroxide, which may interfere with the therapeutic effect or serum concentration of UDCA.
    3. Efficacy is best if started during stage I or II disease but should be started at any stage of disease. Lifelong therapy is currently recommended.
- Treatment also includes treatment of associated conditions such as fatigue, pruritus, osteoporosis, hypercholesterolemia, malabsorption, fat-soluble vitamin deficiencies, anemia, hypothyroidism, and any complications of cirrhosis.

ACUTE GENERAL Rx

- Symptomatic stage: Goals of treatment are resolution of symptoms such as pruritus, treatment of chronic cholestatic complications, and delay of liver failure.
- Obeticholic acid has recently been approved as a second line treatment for PBC.
  1. It is a farnesoid X receptor agonist and is used in combination with UDCA for patients who have an inadequate response to UDCA or as monotherapy for patients who are UDCA non-responders.
  2. It is initially dosed at 5 mg once daily and can be increased to 10 mg once daily after 3 mo if there has been an inadequate decrease in bilirubin and/or ALP.
  3. The most common adverse event noted is pruritus and therefore this drug may not be ideal for patients with that symptom.
- Prednisone, azathioprine, colchicine, methotrexate, fibrates, penicillamine, cyclosporine, silymarin, and mycophenolate mofetil are no longer used because of limited efficacy and/or significant toxicity.
- For the pruritus of PBC, cholestyramine resin (4 to 16 g/day) reduces pruritus in most patients but must be given at least 4 hrs before UDCA to avoid reducing the efficacy of that drug. Antihistamines at bedtime help nighttime symptoms. Rifampin (150 to 300

mg bid), oral opiate antagonists such as naltrexone (12.5 to 50 mg daily) and sertraline (75 to 100 mg daily) can be used for pruritus refractory to bile acid sequestrants. Table 2 summarizes treatment recommendations for pruritus in PBC. Intractable pruritus can be an indication for liver transplantation.
- Newer agents that are being investigated for pruritus include ileal bile acid transporter inhibitors and fibrates.

CHRONIC Rx

- Liver function tests should be checked every 3 to 6 mo.
- Management of sicca syndrome: Artificial tears can be used initially for dry eyes. Saliva substitutes can be used for xerostomia and dysphagia; pilocarpine or cevimeline can be used for refractory cases. Moisturizers can be given for vaginal dryness.
- Treatment/Prevention of osteopenia/osteoporosis: Patients with PBC should be given 1000 to 1200 mg calcium daily in divided doses and 1000 IU of vitamin D daily in the diet and as supplements if needed. Weight-bearing exercises are also recommended. Bone densitometry should be done at time of diagnosis, after a fragility fracture, in patients with cirrhosis, prior to transplant, or in patients receiving steroids more than 3 mo. It should then be performed every 2 to 4 yr. Alendronate (70 mg weekly) or other bisphosphonates should be considered if patients have osteopenia in the absence of acid reflux or known varices.
- Hyperlipidemia is common in patients with PBC. However, there is no elevated risk of cardiovascular disease. Statins are safe and effective in patients who may need treatment even if liver chemistry is abnormal.
- Vitamin A, K, and E deficiencies can be clinically important in advanced cases and respond to oral replacement.
- Upper endoscopy to assess for varices is indicated every 1 to 3 yr in patients with cirrhosis or Mayo risk score >4.1. Nonselective beta-blockers or endoscopic banding can be considered for prevention of variceal hemorrhage.
- Regular screening for hepatocellular carcinoma with ultrasound and α-fetoprotein every 6 mo is recommended for patients with cirrhosis.
- Liver transplantation is the only effective treatment for patients with liver failure, and approximately 25% of PBC patients ultimately need a liver transplant. Indications for transplantation include hepatic decompensation (encephalopathy, recurrent variceal bleeding, intractable ascites and spontaneous bacterial peritonitis), hepatocellular carcinoma fulfilling Milan criteria (see "Hepatocellular Carcinoma"), and intractable pruritus. Liver transplant should also be considered with a Mayo risk score >7.8, MELD score >12, and bilirubin ≥ 6 mg/dl.
- The outcome of liver transplantation for patients with PBC is more favorable than that of nearly all other liver disease categories. The survival rates at 1 yr are now up to 90% to 95%. Although recurrent disease may develop in 11% to 42% of patients after liver transplantation within a median of 47 mo, patient and graft survival is usually not affected.

DISPOSITION

Definitive treatment requires liver transplantation. Among untreated patients transplant-free survival is 79%, 59%, and 32% at 5, 10, and 15 yr, respectively.

REFERRAL

Gastroenterology and/or hepatology for treatment, evaluation for liver transplantation, and management of portal hypertension.

Primary Biliary Cirrhosis (PBC) (Patient Information)

AUTHORS: **Jeanette G. Smith, MD,** and **Dina A. Ibrahim, MD**

TABLE 2 Current Recommendations for Treatment of Pruritus in Primary Biliary Cholangitis

Approach	Drug	Mechanism of Action	Dose	Adverse Effects	Comments
First line	Cholestyramine	Bile acid resin	4-16 g/day	Unpleasant taste, bloating, constipation, and diarrhea	Morning dose preferred; separate at least 3 hr from other drugs
	Colesevelam	Bile acid resin	3.75 g/day in two or three divided doses	As above (but less frequent), headache, myalgia	Separate at least 3 hr from other drugs
Second line	Rifampicin (rifampin)	Pregnane X receptor (PXR) agonist and enzyme inducer	150-600 mg/day	Hepatitis, liver failure, hemolysis	150 mg/day when serum bilirubin level <3 mg/dl; 300 mg/day when serum bilirubin level >3 mg/dl; regular monitoring of blood count and liver biochemistry
Third line	Naltrexone	Opiate mu receptor antagonist	50 mg/day	Opioid withdrawal–like reaction—abdominal pain, high blood pressure, tachycardia, goose bumps, nightmares	Start at 12.5 mg/day; increase gradually; regular monitoring of liver biochemistry
Fourth line	Sertraline	Serotonin reuptake inhibitor (SSRI)	100 mg/day	Nausea, dizziness, diarrhea, visual hallucinations, increased fatigue	Start at 25 mg/day; increase gradually

Primary Chest Wall Tumors

BASIC INFORMATION

DEFINITION

Primary chest wall tumors are a heterogeneous group of rare neoplasms originating from soft tissue, bone, or cartilage of chest wall. Approximately 50% to 80% of chest wall tumors are malignant; approximately 55% arise from bone cartilage and 45% from soft tissue. Chondrosarcomas are the most common primary chest wall sarcoma. The most common soft-tissue primary malignant tumors are fibrosarcomas and malignant fibrous histiocytomas. The most common benign chest wall tumors are osteochondroma, chondroma, and fibrous dysplasia.

ICD-10CM CODES

R22	Localized swelling, mass and lump of skin, and subcutaneous tissue
R22.2	Localized swelling, mass and lump, trunk
C41	Malignant neoplasm of bone and articular cartilage of other unspecified sites
C49.9	Malignant neoplasm of connective and soft tissue, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- 1% to 2% of all new cancer diagnosed and 5% of all thoracic neoplasm.
- More common in the elderly.
- Ewing sarcoma and rhabdomyosarcoma are the most common tumors in children.
- Chondrosarcoma, lymphoma, or solitary plasmacytoma are more frequently seen in the adult.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Palpable enlarging mass over the chest wall or pain.
- Soft tissue masses are usually painless but skeletal lesions can be painful from periosteal invasion.
- Weakness and atrophy of upper extremities can be found from compression of a tumor on the brachial plexus.
- Patients with malignant neoplasms are typically older than patients with benign tumors (60 vs. 42 yrs) and have larger tumors (9 vs. 7 cm).

ETIOLOGY

- Most primary chest wall tumors arise sporadically
- Risk factors: Previous radiation treatment, chronic lymphedema, or exposure to chemicals
- Genetic predispositions: Neurofibromatosis type 1 or familial retinoblastoma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bone tumors:
  1. Benign: Fibrous dysplasia, osteochondroma, chondroma, Langerhans cell/histiocytosis/eosinophilic granuloma, aneurysmal bone cyst, osteoid osteoma, osteoblastoma, and giant cell tumor
  2. Malignant: Chondrosarcoma, Ewing sarcoma, osteosarcoma, and solitary plasmacytoma
- Soft tissues:
  1. Benign: Lipomas, lipoblastoma, fibroma, fibromatosis, hemangiomas, benign peripheral nerve sheath tumors, and mesenchymal hamartomas
  2. Malignant: Malignant fibrous histiocytoma, synovial sarcomas, rhabdomyosarcoma, fibrosarcoma, and metastatic disease

IMAGING STUDIES

- Chest x-rays (CXR) can reveal sclerotic or lytic bone lesions.
- Chest CT to assess the extent of size, location, and structure involvement such as soft tissue, bone, pleura, vessels, mediastinal area, or lung metastasis. It is also useful in estimating post-resection defect to plan for reconstruction surgery.
- MRI is now a preferred imaging modality to assess primary chest wall tumors. It provides better-detailed information on soft tissue, vascular, and nerve involvement and extension to the spine or thoracic inlet. Malignant tumors usually appear dark on T1-weighted MRI and bright on T-weighted MRI images.

BIOPSY

- Excisional biopsy is preferred for lesions less than 2 cm, thought to be benign and possible for primary closure.
- Incisional biopsy should be considered for lesions larger than 2 cm. A minimum of 1 cm^3 is recommended.
- Fine-needle aspiration biopsy can give high diagnostic accuracy with ancillary techniques such as immunohistochemical stain or cytogenetic analysis.
- Core needle biopsy can be used for deep lesions under the guidance of imaging modalities.

LABORATORY TEST

Cytogenetic analysis is widely used to increase diagnostic accuracy and is sometimes helpful for making the therapeutic decision.

TREATMENT

- Surgical resection and reconstruction are the main principles of treatment.
- Baseline pulmonary function test should be obtained prior to the surgery to determine resection candidacy. Extensive chest wall resection can compromise pulmonary function.
- Systemic treatment and radiation are often combined with surgery as adjuvant or neoadjuvant treatment for malignant disease.
- Isolated plasmacytoma can be treated with chemotherapy or radiation (see “Multiple Myeloma”).
- Metastatic or locally advanced soft tissue sarcomas: Systemic treatment with cytotoxic agent or tyrosine kinase inhibitor (Pazopanib).

FOLLOW UP

- Evaluation for rehabilitation (OT, PT). Continue until maximal function is achieved.
- H&P every 3 to 6 mo for 2 to 3 y, then every 6 mo for next 2 yr, then annually.
- Imaging of chest and other known sites of metastatic disease.
- Consider obtaining postoperative baseline and periodic imaging of primary site based on estimated risk of locoregional recurrence.

Primary Immunodeficiency Disease (ALG)

BASIC INFORMATION

DEFINITION

Primary immunodeficiency diseases (PIDDs) are a collection of >200 rare disorders involving the absence or malfunction of integral parts of the immune system. The etiologies of PIDDs are not communicable in the infectious sense, but vertically transmissible via transfer of inherited genetic defects. Although some defects affect a single part of the immune system, others cause multicomponent breakdown of combined innate and cellular immune responses and suggest the interplay of epigenetic influences. To be considered a PIDD, the cause must not be secondary to another disease, drug/chemical, or environmental exposure. Primary immunodeficiency disease onset may occur at birth, as most do, or at any subsequent developmental stage and may affect anyone, with only specific regard to gender or ethnicity.

SYNONYMS

PID
PIDD
PI

ICD-10CM CODES

D80.5	Immunodeficiency with increased immunoglobulin M [IgM]
D80.9	Immunodeficiency with predominantly antibody defects, unspecified
D81.0	Severe combined immunodeficiency [SCID] with reticular dysgenesis
D81.1	Severe combined immunodeficiency [SCID] with low T- and B-cell numbers
D81.2	Severe combined immunodeficiency [SCID] with low or normal B-cell numbers
D81.9	Combined immunodeficiency, unspecified
D82.2	Immunodeficiency with short-limbed stature
D82.3	Immunodeficiency following hereditary defective response to Epstein-Barr virus
D82.8	Immunodeficiency associated with other specified major defects
D82.9	Immunodeficiency associated with major defect, unspecified
D83.0	Common variable immunodeficiency with predominant abnormalities of B-cell numbers and function
D83.1	Common variable immunodeficiency with predominant immunoregulatory T-cell disorders
D83.2	Common variable immunodeficiency with autoantibodies to B- or T-cells
D83.9	Common variable immunodeficiency, unspecified
D84.9	Immunodeficiency, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

Overall about 1:500 are born with and 1:1200 currently live with a PIDD, these numbers generally exclude the milder forms of immunodeficiency (e.g., IgA deficiency). The predilection for age and gender varies according to the specific disorder.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The history, signs, and symptoms depend on the precise genetic disorder. Recurrent, persistent, or unusual infections, as well as developmental delay or congenital anomalies, are among the most common attributes present when considering a primary immunodeficiency as a potential diagnosis.

ETIOLOGY

Inherited

DIAGNOSIS

Criteria for the diagnosis of common variable immunodeficiency disease are summarized in Box E1. The International Union of Immunological Societies (IUSIS) PID expert committee has set forth a PID classification system that is updated every other year. The PIDs are grouped into eight categories, based on the primary mechanism of each disease. Due to the complexity of the classification system in clarifying a PID case and the reasoning that most PIDs will present in nonimmunological fields of medicine, a phenotype-based algorithmic approach highlighting the clinical and biological characteristics of a particular PID has been synthesized to aid in diagnosis (Fig. E1).

- Combined T-cell and B-cell immunodeficiencies (Boxes E2 and E3)
- Well-defined syndromes with immunodeficiency (Table E1)
- Predominantly antibody deficiencies (Table E2)
- Disease of immune dysregulation
- Congenital defects of phagocyte number, function, or both
- Defects of innate immunity (Box E4)
- Autoinflammatory disorders
- Complement deficiencies (Table E3)

DIFFERENTIAL DIAGNOSIS

Secondary immunodeficiency, primary infections

WORKUP

A thorough history detailing the type, location, and frequency of the infections, as well as any physical exam findings that may indicate recurrent or persistent infections (e.g., scarred tympanic membranes) is essential in the initial characterization of the suspect immunodeficiency (Table E4). Box E5 summarizes when to suspect an immunodeficiency disorder. Screening tests for suspected primary immunodeficiency disease are summarized in Table E5.

LABORATORY TESTS

- Screening tests:
  1. Complete blood count with a manual differential: The most important test upon initial evaluation is whether lymphocyte, neutrophil, and platelet counts are normal.
  2. Quantitative immunoglobulin levels (IgG, IgA, IgM, IgE): The specimen should be processed at a CLIA (Clinical Laboratories Improvement Act)-approved laboratory and be evaluated within the context of the patient's age and clinical presentation.
  3. Vaccine responsive antibody quantification: Important to the evaluation of an antibody deficiency disorder is evaluating whether there are truly low serum immunoglobulin responses to both polysaccharide- and protein-based vaccines. Table E6 describes antibody specificities commonly used in flow cytometry for immunodeficiency assessment.
  4. Any further investigation should defer to an immunologist for guidance based on history, symptoms, and clinical presentation and may involve a more precise analysis of immunoglobulin subtypes, T and B lymphocytic subsets, cell surface markers, complement levels, and gene sequencing.

TREATMENT

Treatment depends highly on the specific immunodeficiency and should always include

BOX E1 Criteria for the Diagnosis of Common Variable Immunodeficiency Disease

- At least one of the following:
  1. Increased susceptibility to infection
  2. Autoimmune manifestations
  3. Granulomatous disease
  4. Unexplained polyclonal lymphoproliferation
  5. Affected family member with antibody deficiency
- *And* marked decrease of IgG and marked decrease of IgA with or without low IgM levels (measured at least twice; <2 standard deviations below the normal levels for age)
- *And* at least one of the following:
  1. Poor antibody response to vaccines (and/or absent isohemagglutinins)
  2. Low switched-memory B cells (<70% of the age-related normal value)
- *And* secondary causes of hypogammaglobulinemia have been excluded
- *And* diagnosis is established after the fourth yr of life (although symptoms may present before that age)
- *And* no evidence of severe T-cell deficiency, defined as two of the following:
  1. CD4+ cells/mm^3: 2-6 yr, <300; 6-12 yr, <250; >12 yr, <200
  2. Naive CD4+ %: 2-6 yr, <25; 6-16 yr, <20; >16 yr, <10
  3. Significantly decreased T-cell proliferation to stimulation

Ig, Immunoglobulin.
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

primary treatment and prophylaxis of the offending infectious agents. Key concepts in the management of primary immunodeficiencies are summarized in Box E6. Education on the necessary precautions to minimize potential infections is crucial. A systematic consideration of the appropriate vaccinations is key to avoid any unnecessary infections or complications. Specific PIDDs carry the risk of malignancies and require regular screenings.

Immunoglobulin replacement is standard treatment for most primary immunodeficiencies to reduce the incidence of serious bacterial infections. Available immunoglobulin G products include Hyquia, Gammagard liquid, Gamune XC, and Hizentra. The newest FDA-approved product is Hyquia. It contains human immune globulin 10% with recombinant hyaluronidase. It is administered subcutaneously every 3 to 4 wk. It has dosing advantages compared to other immune globulin subcutaneous (IGSC) products, but may be more difficult to self-administer because of the need to give hyaluronidase first. The risk of immunogenicity with chronic exposure to recombinant human hyaluronidase is a concern, and its safety in children has not been established.[1]

[1]A new subcutaneous immune globulin (HyQvia) for primary immunodeficiency, *Med Lett Drugs Ther* 57(1476):121-122, 2015.

NONPHARMACOLOGIC THERAPY

Surgical intervention may be necessary for specific congenital malformations and possibly if malignancy is identified. In the case of a severe combined immune deficiency, patient bone marrow transplantation may be a therapeutic option.

PATIENT & FAMILY EDUCATION

Due to the nature of primary immunodeficiencies, affecting both the patient and family members, genetic counseling is key to comprehensive patient care. Although immunologists are well versed in the genetic inheritance of the PIDDs, referral to a genetic counselor is often advised.

BOX E2 Screening Tests for B-Cell Immune Function

Screening Tests
- Quantitative serum immunoglobulins
- Specific antibodies to vaccine responses
  1. Tetanus, diphtheria (IgG1)
  2. Pneumococcal and meningococcal polysaccharides (IgG2)
  3. Viral respiratory pathogens (IgG1 and IgG3)
  4. Other vaccines: Hepatitis B, influenza, MMR, polio (killed vaccine)
- Isohemagglutinins (IgM antibodies to A and B blood group antigens)
- B-cell quantitation by flow cytometry

Advanced Testing
- In vitro B-cell immunoglobulin production
- Regulation of immunoglobulin synthesis
- CD40 ligand–CD40 interactions
- B-cell subsets: Nonswitched and switched memory B-cells
- Molecular analysis for gene deletions or mutations

IgG, Immunoglobulin G; *MMR,* measles, mumps, rubella vaccine.
From Adkinson NF et al: *Middleton's allergy: principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.

BOX E3 Screening Tests for Innate Defense Factors

Screening Tests
- Absolute granulocyte count, cell morphology
- Serum total hemolytic complement (CH_{50}), alternative pathway hemolytic activity (AP_{50})
- Nitroblue tetrazolium (NBT) test or flow cytometry using dihydrorhodamine dye test
- Flow cytometry for leukocyte adhesion molecules (CD11/CD18 and CD15a)

Advanced Testing
- Phagocytic assays
- Chemotaxis assays
- Analysis of Toll-like receptor pathways
- Molecular analysis for specific defects

From Adkinson NF et al: *Middleton's allergy: principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.

TABLE E1 Antibody and B-Cell Deficiencies

Disease	Functional Deficiencies	Mechanism of Defect
Agammaglobulinemia		
X-linked	Decrease in all serum Ig isotypes; reduced B-cell numbers	Pre-B receptor checkpoint defect; Btk mutation
Autosomal recessive forms	Decrease in all serum Ig isotypes; reduced B-cell numbers	Pre-B receptor checkpoint defect; mutations in IgM heavy chain (μ), surrogate light chains, Igα, BLNK
Hypogammaglobulinemia, isotype defects		
Selective IgA deficiency	Decreased IgA; may be associated with increased susceptibility to bacterial infections and protozoa such as *Giardia lamblia*	*TACI* mutations in some patients
Selective IgG2 deficiency	Increased susceptibility to bacterial infections	Small subset has deletion in IgG2 locus
Common variable immunodeficiency	Hypogammaglobulinemia; normal or decreased B-cell numbers	*ICOS* and *TACI* mutations in some patients
ICF syndrome	Hypogammaglobulinemia; occasional mild T-cell defects	*DNMT3B* mutations
Hyper-IgM Syndromes		
X-linked	Defects in helper T-cell–mediated B-cell, macrophage, and dendritic cell activation; defects in somatic mutation, class switching, and germinal center formation; defective cell-mediated immunity	*CD40L* mutations
Autosomal recessive with cell-mediated immune defects	Defects in helper T-cell–mediated B-cell, macrophage, and dendritic cell activation; defects in somatic mutation, class switching, and germinal center formation; defective cell-mediated immunity	*CD40, NEMO* mutations
Autosomal recessive with antibody defect only	Defects in somatic mutation and isotype switching	*AID, UNG* mutations

AID, Activation-induced cytidine deaminase; *BLNK,* B-cell linker; *Btk,* Bruton tyrosine kinase; *DNMT3B,* DNA methyltransferase 3B; *ICF,* immunodeficiencies, centromeric instability, and facial anomalies; *ICOS,* inducible costimulator; *Ig,* immunoglobulin; *NEMO,* NF-κB essential modulator; *TACI,* transmembrane activator and calcium modulator and cyclophilin ligand interactor; *UNG,* uracil *N*-glycosylase.
From Adkinson NF et al: *Middleton's allergy: principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.

TABLE E2 Predominant Antibody Deficiencies

	Disease	Mode of Inheritance/Genetic Locus	Clinical Features
Severe reduction in all serum immunoglobulin isotypes with absent B cells	Bruton tyrosine kinase deficiency	XL/Xq21.3-22	Severe bacterial infections (especially of the respiratory tract), absent lymphoid tissue
	μ heavy chain deficiency	AR/14q32.3	Severe bacterial infections
	λ5 deficiency	AR/22q11.21	Severe bacterial infections
	Igα deficiency	AR/19q13.2	Severe bacterial infections
	Igβ deficiency	AR/17q23	Severe bacterial infections
	BLNK deficiency	AR/10q23.2	Severe bacterial infections
	SP110 deficiency	AR/2q37.1	Hepatic venoocclusive disease, some with frequent infection
	LRRC8A deficiency	AD/9q34.11	Facial anomalies
	PIK3R1	AR/5q13.1	Recurrent bacterial infection
	Thymoma with immunodeficiency (Good syndrome)	None	Recurrent infection with encapsulated bacteria and diarrhea, autoimmune phenomena
	Myelodysplasia	Variable/monosomy 7, trisomy 8, dyskeratosis congenita	Recurrent infections and pancytopenia
Severe reduction in at least two serum immunoglobulin isotypes with low or normal B-cell numbers	Common variable immunodeficiency syndromes	≈10% with family history AR or AD	Recurrent respiratory tract infections leading to chronic sinusitis, hearing loss, bronchiectasis, autoimmune disease, lymphoproliferation, malignancy (especially non-Hodgkin lymphoma and gastric carcinoma)
	TACI alterations	AD and AR/17p11.2	
	BAFFR alterations	AR/22q13	
	MSH5 alterations	Unk/6p22.1-p21.3	
	ICOS deficiency	AR/2q33	Recurrent infections
	CD19 deficiency	AR/16p11.2	Recurrent infections
	X-linked lymphoproliferative disease (mutation in SH2 domain protein 1A)	XL/Xq25-q26	Fulminant infection with EBV, lymphoma, dysgammaglobulinemia
	CD81 deficiency	AR/11p15.5	Recurrent infections
	CD20 deficiency	AR/11q12.2	Recurrent infections
	CD21 deficiency	AR/1q32.2	Recurrent infections
	LRBA deficiency	AR/4q31.3	Recurrent infections, inflammatory bowel disease, EBV infection
	TNSF12 deficiency	AD/17p13.1	Recurrent bacterial infections, thrombocytopenia, neutropenia
	NFKB2 deficiency	AD/10q24.32	Recurrent infections
	CXCR4 activation	AD gain of function/2q22.1	WHIM syndrome
Severe reduction in serum IgG and IgA with increased IgM and normal B-cell numbers (disorders of immunoglobulin class switching)	CD40 ligand deficiency	XL/Xq26.3-Xq27.1	Recurrent infections with bacteria and opportunistic pathogens, neutropenia, autoimmune disease
	CD40 deficiency	AR/20q11-20q13.2	Recurrent infections with bacteria and opportunistic pathogens, neutropenia, autoimmune disease
	NEMO hypomorphic mutations	XL/Xq28	Recurrent infections with bacteria and opportunistic pathogens, neutropenia, autoimmune disease
	AID deficiency	AR/12p13	Recurrent bacterial infections and diarrhea, marked enlargement of lymphoid organs
	UNG deficiency	AR/12q23-q24.1	Recurrent bacterial infections and diarrhea, marked enlargement of lymphoid organs
Isotype or light-chain deficiencies with normal B-cell numbers	Ig heavy-chain deficiency	AR/14q32	Most patients are healthy
	κ-chain deficiency	AR/2p11.2	Most patients are healthy
	Isolated IgG subclass deficiency	Variable/unknown	Most patients are healthy
	IgA deficiency associated with IgG subclass deficiency	Variable/unknown	Most patients are healthy
	Selective IgA deficiency	Variable/unknown	Most patients asymptomatic, but increased prevalence of infections, autoimmune disease, atopy, and celiac disease
	PRKCδ deficiency	AR/3p21.1	Recurrent infection, autoimmunity, and chronic EBV infection
	Activated PI3K-γ	AD gain of function/1p36.22	Recurrent infection, autoimmunity, chronic EBV, and CMV infection
Specific antibody deficiency with normal immunoglobulin level and B-cell number	Inability to make antibodies to specific antigens	Variable/unknown	Recurrent sinopulmonary infection, bronchiectasis, diarrhea, autoimmune disease
Transient hypogammaglobulinemia of infancy	IgG and IgA deficiency	Variable/unknown	More likely to be male (60%-80%), mild infections and diarrhea, atopy

λ5, Immunoglobulin lambda-like polypeptide (a surrogate light chain subunit that is part of the pre–B-cell receptor); *AD,* autosomal dominant; *AID,* activation-induced cytidine deaminase (thought to be essential for initiation of the DNA cleavage required for class-switch recombination and somatic hypermutation); *AR,* autosomal recessive; *BAFFR,* B-cell–activating factor receptor; *BLNK,* B linker (a cytoplasmic linker or adaptor protein that plays a critical role in B-cell development); *CMV,* cytomegalovirus; *CXCR4,* CXC-chemokine receptor 4 (mediates migration of resting leukocytes and hematopoietic progenitors in response to its ligand, stromal cell–derived factor 1 [SDF1]); *EBV,* Epstein–Barr virus; *ICOS,* inducible T-cell costimulator (belongs to CD28 family of costimulatory surface molecules); *Ig,* immunoglobulin; *Igα,* immunoglobulin-associated α (necessary for expression and function of the B-cell antigen receptor); *Igβ,* immunoglobulin-associated β (necessary for expression and function of the B-cell antigen receptor); *LRBA,* lipopolysaccharide-responsive, beige-like anchor protein (implicated in regulating endosomal trafficking, particularly endocytosis of ligand-activated receptors); *MSH5, mutS* homolog 5 (a protein involved with DNA mismatch repair and meiotic recombination); *NEMO,* NFκB essential modulator; *NFκB,* nuclear factor kappa-B; *PI3K-γ,* protein kinase C family member (critical for regulation of cell survival, proliferation, and apoptosis); *PRKCδ,* member of the protein kinase c family (involved in B-cell receptor-mediated signaling); *TACI,* transmembrane activator and CAML-interactor; *TNSF12,* tumor necrosis factor ligand superfamily, member 12 (weak inducer of apoptosis); *UNG,* uracil DNA glycosylase (allows creation of single-stranded breaks essential to class switch recombination and somatic hypermutation); *WHIM,* warts, hypogammaglobulinemia, infections, and myelokathexis; *XL,* X-linked.

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

BOX E4 Screening Tests for T-Cell Immunity

Screening Tests
- Newborn screening for TREC analysis (not available in all states)
- Absolute lymphocyte count
- Chest radiograph for thymus shadow in newborns
- Delayed skin hypersensitivity to recall antigens
- Quantification of T-cell subsets

Advanced Testing
- Lymphocyte proliferative responses to mitogens, antigens, and allogeneic cells in MLC
- Lymphocyte-mediated cytotoxicity: NK and ADCC activity
- Production of cytokines
- Functional response to cytokines
- Signal transduction studies
- Molecular analysis for specific defects

ADCC, Antibody-dependent cellular cytotoxicity; *MLC,* mixed lymphocyte culture; *NK,* natural killer; *TREC,* T-cell receptor excision circles.
From Adkinson NF et al: *Middleton's allergy: principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.

TABLE E3 Inherited Complement Deficiencies

Deficiency	Chromosomal Location	Number of Cases Reported	Clinical Features; Diagnostic Strategy
C1q	1	10-100	SLE, infections; CH50 near zero
C1r/s	12	10-100	SLE, infections; CH50 near zero
C4	6	10-100	SLE, infections; CH50 near zero
C2	6	Many	SLE, infections, some asymptomatic; CH50 near zero
C3	19	10-100	Infections frequent and severe, glomerulonephritis; CH50 near zero
Factor D	19	<10	*Neisseria*; AH50 near zero
Factor B	6	<10	*Neisseria*; AH50 near zero
Properdin	X	>100	*Neisseria*; AH50 diminished
MBL	10	Millions	Most asymptomatic infections, SLE; CH50 normal, MBL assay required
C5	9	10-100	*Neisseria*; CH50 near zero
C6	5	>100	*Neisseria*; CH50 near zero
C7	5	>100	*Neisseria*; CH50 near zero
C8	1 and 9	>100	*Neisseria*; CH50 near zero
C9	5	Many	*Neisseria*; CH50 diminished
Factor I	4	10-100	*Neisseria*, HUS; C3 may be diminished, many require mutation analysis
Factor H	1	10-100	*Neisseria*, HUS; C3 may be diminished, many require mutation analysis
MCP	1	<10	HUS; mutation analysis required
C1 inhibitor	11	Many	Angioedema; C1 antigen and functional levels
CR3/CR4	16	>100	Leukocyte adhesion deficiency, very severe systemic infections, lack of pus; flow cytometry
CD59	11	<10	Paroxysmal nocturnal hemoglobinuria; flow cytometry

AH50, Serum dilution that lyses 50% of a red cell suspension; *CH50,* serum dilution that lyses 50% of a red cell suspension; *HUS,* hemolytic uremic syndrome; *MBL,* mannose-binding lectin; *MCP,* membrane cofactor protein; *SLE,* systemic lupus erythematosus.
From Adkinson NF et al: *Middleton's allergy: principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.

TABLE E4 Physical Examination of Patients with Recurrent Infection

Diagnosis and Physical Findings	
Growth Failure	Sinusitis
SCID	Purulent nasal discharge
Dysmorphisms	Purulent postpharyngeal exudate
Micrognathia, short philtrum, ear anomalies	Pharyngeal cobblestoning
Short-limbed dwarfism	Dentition, gums
Hypertelorism, epicanthal folds, flat nasal bridge	Conical teeth
Ectodermal dysplasia	Periodontitis
Coarse facies	**Respiratory Tract**
Skin and oral mucosa	Digital clubbing
Rashes	Rales
Lupus-like malar rash	**Wheezing Cardiac System**
Dermatomyositis rash	Heart murmur (conotruncal abnormalities)
Erythroderma	**Lymphatic System**
Eczema	Absent tonsils, lymph nodes
Petechiae	Diffuse lymphoid hyperplasia
Pyoderma, abscesses	Lymphadenitis
Poor wound healing	**Musculoskeletal System**
Candidiasis	Arthralgia, arthritis
Telangiectasia	Dermatomyositis
Delayed umbilical cord separation	Lupus-like syndrome
Abnormal hair	Short-limb dwarfism
Ears, Nose, Throat, and Mouth	Craniosynostosis
Chronic otitis media	**Neurologic System**
Dull tympanic membranes	Ataxia
Poor light reflex	Enteroviral meningoencephalitis
Scarring	Neuropathies
Perforations of the tympanic membrane	Pernicious anemia

SCID, Severe combined immunodeficiency.
From Adkinson NF et al: *Middleton's allergy: principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.

BOX E5 When to Suspect an Immunodeficiency Disorder

- Frequency of infectious illnesses higher than expected
- Unusual severity or duration of infectious disease
- Poor response to conventional antibiotic therapy
- Unusual organisms or opportunistic infections causing disease
- Failure to thrive secondary to frequent illnesses
- Poor wound healing
- Noninflammatory *Staphylococcus* spp. skin infection (or absence of pus)
- Recurrent periodontitis
- Low granulocyte or lymphocyte count

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

TABLE E5 Screening Tests for Suspected Primary Immunodeficiency Disease

Immunodeficiency	Screening Tests
All types	Complete blood cell count
	Peripheral blood smear
Antibody deficiency	Quantitative serum immunoglobulins: IgG, IgA, IgM, IgE
	Postimmunization specific IgG antibody titers
	Isohemagglutinins
T-cell deficiency	Delayed hypersensitivity skin tests or lymphocyte proliferation response to mitogens
	Chest imaging studies for thymus size
	Lymphocyte subset phenotyping
Complement deficiency	Total hemolytic complement (CH50) assay
Phagocyte deficiency	Dihydrorhodamine (DHR)-1,2,3 reduction by flow cytometry
	Neutrophil CD18 and CD15 expression

Ig, Immunoglobulin.
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

TABLE E6 Antibody Specificities Commonly Used in Flow Cytometry for Immunodeficiency Assessment

Antibody Designation	Detection on Normal Cells
CD2	Pan–T-cell, NK cells (80%-95% of T lymphocytes)
CD3	Mature pan–T-cell (95% of T lymphocytes)
CD4	Helper/inducer T-cells (65% of T lymphocytes) and monocytes
CD8	Cytotoxic/suppressor T-cells (35% of T lymphocytes)
CD14	Maturing monocytes
CD16	Granulocytes, NK cells
CD19	Pan–B-cell lymphocyte
CD20	Maturing B-cells (surface immunoglobulin–positive B lymphocytes)
CD34	Immature hematopoietic cells, stem cells
CD41	Platelets and megakaryocytes
CD45	Leukocyte common antigen
CD56	NK cells, some stem cell disorders
HLA-DR	Myeloid blasts, B-cells, activated T-cells (90% of B lymphocytes and monocytes)
Common Monoclonal Antibody Panel Specificities	
To evaluate lymphocyte purity and recovery	CD45, CD14 (two-color)
To evaluate helper/inducer T-cell population	CD3, CD4 (two-color)
	CD3, CD4, CD45 (three-color)
	CD3, CD4, CD45, CD8 (four-color)
To evaluate cytotoxic/suppressor T-cell population	CD3, CD8 (two-color)
	CD3, CD8, CD45 (three-color)
To evaluate B-cell lymphocyte population	CD3, CD19 (two-color)
	CD3, CD19, CD45 (three-color)
	CD3, CD19, CD45, CD16 (four-color)
To evaluate NK cell population	CD3, CD16 and/or CD56 (two-color)

HLA, Human leukocyte antigen; *NK,* natural killer.
From Adkinson NF et al: *Middleton's allergy: principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.

BOX E6 Key Concepts in the Management of Primary Immunodeficiencies

Immune function: T- and B-cell number and function should be assessed periodically.
IgG replacement therapy: Infusions are indicated for patients with poor antibody responses to immunizations.
Immunizations: Live vaccines should not be administered to patients who have severe T-cell deficiencies unless they have received definitive treatment. Household contacts of children with immunodeficiency should not receive oral poliovirus vaccines because of the risk for transmission to the immunodeficient child. Other live vaccines (BCG, MMRV) may be administered to household contacts. If the vaccine recipient develops a rash, contact with the immunodeficient child should be avoided.*
Blood products: When needed, patients with immune deficiencies should receive only irradiated, cytomegalovirus-negative, leukocyte-depleted blood products.
Antibiotic prophylaxis: T-cell–deficient patients should be given antibiotic prophylaxis to prevent *Pneumocystis jirovecii* infection. Antibiotic prophylaxis is recommended for dental and surgical procedures and should be considered for patients with recurrent infections.
Infectious diseases: Infections should be recognized promptly, and unusual pathogens should be considered. Antibiotic therapy should be started early and discontinued cautiously.
Diet and activity: Patients with immune deficiency should have a regular diet and lifestyle but should be instructed to avoid eating raw food and playing in environments potentially highly contaminated with pathogens, including daycare centers. Strict hand-washing precautions and reverse isolation may be indicated for patients with poor T-cell function.

BASIC INFORMATION

DEFINITION

Primary myelofibrosis (PMF) is a clonal stem cell disorder characterized by chronic myeloproliferation, atypical megakaryocytic hyperplasia, bone marrow fibrosis (Fig. E1), and extramedullary hematopoiesis in the spleen and liver primarily. Prefibrotic/early myelofibrosis is a recently defined World Health Organization entity with marrow findings typical of myelofibrosis but with less overt fibrosis.

ICD-10CM CODES

C94.40	Acute panmyelosis with myelofibrosis not having achieved remission
C94.41	Acute panmyelosis with myelofibrosis, in remission
C94.42	Acute panmyelosis with myelofibrosis, in relapse
D75.81	Myelofibrosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (U.S.): ~1.9 per 100,000, age >75 yr; 0.7 per 100,000, age 50 to 74 yr; 0.1 per 100,000, age 35 to 49 yr

PREDOMINANT SEX AND AGE:

- Women 35% lower risk, African ancestry 25% lower risk
- Median age of diagnosis is ~67 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

COMMON SYMPTOMS:

- Fatigue (variably reported 30% to 90%)
- Early satiety, abdominal fullness (~70%)
- Abdominal pain (~45%, may be severe if splenic infarction)
- Weight loss (~50%)
- Other reported symptoms: fever, bone pain, itching, night sweats, diarrhea (attributed to effect of splenic enlargement on bowel)
- Back pain and spinal cord compression from extramedullary hematopoiesis are rare complications of PMF

CLINICAL FINDINGS

- Splenomegaly (most)
- Hepatomegaly (~50%)
- Anemia (50% +), leukocytosis or leukopenia, thrombocytosis, or thrombocytopenia
- Elevated lactate dehydrogenase (LDH)
- Leukoerythroblastic changes in peripheral blood—immature myeloid cells (the bone marrow in the peripheral blood), nucleated red blood count (RBC), teardrop RBC. Rare blast may be seen in chronic-phase disease
- Portal hypertension (5% to 10%)—due to increased blood return from splenic vein, hepatic involvement with extramedullary hematopoiesis (EMH), or venous thrombosis. May cause variceal bleeding and ascites
- Unexpected bleeding, thrombosis including portal, splenic mesenteric and hepatic vein thrombosis (Budd-Chiari syndrome)
- Manifestations of EMH—rarely involving lung (pulmonary hypertension), paraspinal lesions with neurologic symptoms, central nervous system, kidney. More common after splenectomy
- Leukemic transformation 8% to 23% within first 10 yr; risk varies by risk score and genetics
- Table E1 summarizes symptoms and physical findings of patients with primary myelofibrosis detected at diagnosis. Medical disorders associated with myelofibrosis are summarized in Table E2

ETIOLOGY

- Clonal disorder of multipotent hematopoietic progenitors arising from the hematopoietic stem cell compartment.
- The *JAK-2* V617F mutation (present in 50% to 60% cases) results in a substitution of valine for phenylalanine at codon 617 in the pseudokinase domain of *JAK-2*, an enzyme in the Janus family of cytoplasmic nonreceptor tyrosine kinases in erythroid progenitors. The mutation causes constitutive activation of *JAK-2* and increased proliferation signals to hematopoietic precursors.
- Calreticulin exon 9 mutations (present in 20% cases) are either type I or type II; type I mutations confer a more favorable prognosis.
- Somatic mutations of *cMPL*, the gene coding for the thrombopoietin gene, are present in about 10%.
- Approximately 10% are "triple negative" for these mutations, which confers a worse prognosis.
- Table E3 describes genetic lesions identified in patients with primary myelofibrosis and outlines the prognostic relevance of the mutation profiles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (BOX E1)

- Myelofibrosis evolving from preexisting polycythemia vera or essential thrombocytosis
- Chronic myelogenous leukemia
- Myelodysplastic syndrome with marrow fibrosis
- Acute myelofibrosis of acute megakaryocytic leukemia

TABLE E1 Summary of Symptoms and Physical Findings of Patients with Primary Myelofibrosis Detected at Diagnosis

Symptom or Finding	Incidence (%)
Asymptomatic	16-30
Fatigue	47-71
Fever	5-15
Weight loss	7-39
Night sweats	6-21
Symptoms due to enlarged spleen	11-48
Bleeding	5-20
Gout or renal stones	6-13
Pallor	60
Petechiae or ecchymoses	15-20
Splenomegaly	89-99
Hepatomegaly	39-70
Peripheral edema	13
Evidence of portal hypertension	2-6
Lymphadenopathy	1-10
Jaundice	0-4

From Hoffman R: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, WB Saunders.

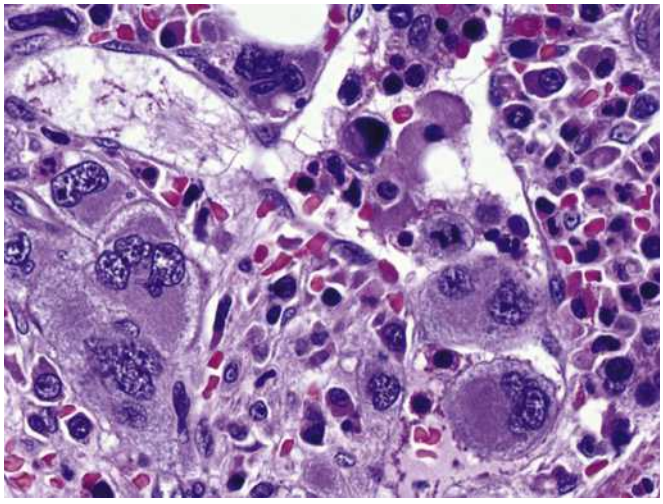

FIG. E1 Bone marrow biopsy in chronic idiopathic myelofibrosis, with increased spacing between cells suggesting fibrosis and intrasinusoidal hematopoiesis (500×). (From McPherson RA, Pincus MR: *Henry's clinical diagnosis and management by laboratory methods,* ed 23, Philadelphia, 2017, Elsevier.)

TABLE E2 Conditions Associated with Myelofibrosis

Nonmalignant Conditions

Infections: Tuberculosis, histoplasmosis
Renal osteodystrophy
Vitamin D deficiency
Hypoparathyroidism
Hyperparathyroidism
Gray platelet syndrome
Systemic lupus erythematosus
Scleroderma
Radiation exposure
Osteopetrosis
Paget disease
Benzene exposure
Thorotrast exposure
Gaucher disease
Primary autoimmune myelofibrosis

Malignant Disorders

Primary myelofibrosis
Other chronic myeloproliferative disorders: polycythemia vera, chronic myeloid leukemia, essential thrombocythemia
Acute myelofibrosis
Acute myeloid leukemia
Acute lymphocytic leukemia
Hairy cell leukemia
Hodgkin lymphoma
Myelodysplasia with myelofibrosis
Multiple myeloma
Systemic mastocytosis
Non-Hodgkin lymphoma
Carcinomas: Breast, lung, prostate, stomach

From Hoffman R: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, WB Saunders.

- Marrow fibrosis associated with hairy cell leukemia, lymphoma, and multiple myeloma
- "TAFRO" syndrome (*t*hrombocytopenia, *a*nasarca, myelo*f*ibrosis, *r*enal dysfunction, *o*rganomegaly), a variant of multicentric Castleman disease
- Nonhematologic disorders with bone marrow fibrosis: solid tumor metastases to the bone marrow, autoimmune disorders, and secondary hyperparathyroidism with vitamin D deficiency
- Table E4 compares key features of major myeloproliferative and myelodysplastic/myeloproliferative disease

LABORATORY TESTS

- CBC:
  1. Anemia (hemoglobin <10g/dl) is common.
  2. Platelet count and white blood cell (WBC) count vary widely; WBC usually elevated.
  3. Peripheral blood smear: Nucleated RBCs, granulocyte precursors, and teardrop-shaped RBCs (leukoerythroblastosis).
  4. "Blasts" may be present in the chronic phase of PMF; this does not by itself indicate leukemic transformation.
- LDH, elevated uric acid
- Bone marrow biopsy: often is a "dry tap"; reveals reticulin fibrosis, increased megakaryocytes

TABLE E3 Diagnostic Molecular Defects in Primary Myelofibrosis and Related Myeloproliferative Neoplasms

Mutation	Chromosome Location	Incidence	Relevance
Janus kinase 2 (*JAK-2*) V617F, c1849G>T, exon 14	9p24	PMF ~60% P Vera ~95% ET ~55%	Causes constitutive activation of *JAK-2*, sending EPO-independent proliferation signals to bone marrow
Calreticulin (*CALR*) Exon 9 Most common variants (80%): Type I: 52 BP deletion c.1092_1143 Type II: 5 BP insertion C1154_1155insTTGTC	19p32.2	PMF ~20% ET ~20% P Vera 0%	Mainly localized to endoplasmic reticulum as "chaperone," involved with glycoprotein folding, calcium hemostasis, other processes
Myeloproliferative leukemia virus (*MPL*) W515L/K, exon 10	1p34	PMF ~10% ET ~3%	Codes for the thrombopoietin receptor

EPO, Erythropoietin; *ET,* essential thrombocytosis; *P Vera,* polycythemia vera; *PMF,* primary myelofibrosis.
Tests for *JAK-2 V617F*, calreticulin exon 9, and *c-mpl W515L/K* are commercially available and may be diagnostically helpful. Numerous other gene mutations have been described. Some, notably *ASXL1* (Additional Sex Combs-Like 1) appear to carry prognostic significance but are not readily available (see Tefferi A: Primary myelofibrosis: 2014 update on diagnosis, risk-stratification, and management, *Am J Hematol* 89:915-925, 2014 for more details).

BOX E1 Diagnostic Criteria for Primary Myelofibrosis

WHO Diagnostic Criteria for Primary Myelofibrosis and Prefibrotic (Early) Primary Myelofibrosis (2016)
Overt Primary Myelofibrosis

Major Criteria

1 Presence of megakaryocytic proliferation and atypia, accompanied by either reticulin and/or collagen fibrosis grade 2 or 3.
2 Not meeting WHO criteria for essential thrombocytosis, polycythemia vera, BCR-ABL1+ chronic myeloid leukemia, myelodysplastic syndrome, or other myeloid neoplasms.
3 Presence of *JAK2*, *CALR*, or *MPL* mutation or in the absence of these mutations, in the presence of another clonal marker, or absence of reactive myelofibrosis.

Minor Criteria

1. Leukoerythroblastosis
2. LDH above institutional upper limit of normal
3. Anemia not attributed to a comorbid condition
4. Palpable splenomegaly
5. Leukocytosis ≥11 × 10^9/L

Diagnosis of overt PMF requires meeting all three major criteria and one minor criteria. Minor criteria should be confirmed in two consecutive determinations.

Preprimary Myelofibrosis
Major Criteria

1. Megakaryocytic proliferation and atypia, without reticulin fibrosis >grade 1, accompanied by increased age-adjusted bone marrow cellularity, granulocytic proliferation, and often decreased erythropoiesis
2. Not meeting the WHO criteria for BCR-ABL1+ CML, PV, ET, myelodysplastic syndrome, or other myeloid neoplasm
3. Presence of *JAK2*, *CALR*, or *MPL* mutations, or in the absence of these mutations, presence of another clonal marker or absence of minor reactive bone marrow reticulin fibrosis

Minor Criteria

1. Presence of at least one of the following, confirmed in two consecutive determinations:
   a. Anemia not attributed to a comorbid condition
   b. Leukocytosis ≥11,000/mcl
   c. Palpable splenomegaly
   d. LDH increased to above upper limit of normal of institutional reference range

Diagnosis of pre-PMF requires all three major criteria and at least one minor criteria.
Arber DA et al: The 2016 revision to the World Health Organization classification of myeloid neoplasms and acute leukemia, *Blood* 127(20):2391-2405, 2016. Details of grading of myelofibrosis can be found in this reference.

LDH, Lactic dehydrogenase; *WHO,* World Health Organization.
From Hoffman R: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, WB Saunders.

TABLE E4 Key Features of Major Myeloproliferative and Myelodysplastic/Myeloproliferative Disease

Disorder	Demographics	Laboratory Features, Morphology	Cytogenetics	Prognosis
CML	Middle-aged	*BCR-ABL* present	t(9:22)(q34;q11) *BCR-ABL1*	Dependent on response to TKI
CNL	Older adults	Neutrophilia >2K/μL	*CSF3R mutation*	Indolent
PV	Middle-aged, M > F	Major criteria: Hb >18.5 g/dl in M or >16.5 g/dl; *JAK2 V617F* (or Exon 12) Minor criteria: hypercellular marrow with panmyelosis; ↓EPO; endogenous erythroid colony formation in vitro; 2 major plus 1 minor, or first major plus 2 minor criteria	*JAK2 V617F* (or exon 12) negative t(9;22)	10-20 yr
PMF	>50 yr	Major criteria: Megakaryocyte proliferation/atypia with marrow fibrosis; CML, PV, MDS ruled out; *JAK2 V617F* Minor criteria: Leukoerythroblastosis, ↑LD, anemia, splenomegaly; all three major plus two minor criteria	*JAK2 V617F*Calreticulin; *TET2, ASXL1, EZH2, CBL,* IDH1/IDH2, TP53, and SRSF2 *mutations;* +8, +9, del(20q), del(13q), del(1p), negative t(9;22)	Dependent on phase: ≈10 yr in early prefibrotic phase; ≈5 yr in fibrotic phase
ET	5th decade (M = F), second peak in 30s (F > M)	Platelet count >450 K; BM with proliferation of mature megakaryocytes; PV, PMF, CML, MDS ruled out; *JAK2 V617F* NOTE: All four criteria must be met.	*JAK2 V617F* in 50%; Calreticulin 40%; del(13q22), +8, +9 seen in 5%-10% of cases; negative t(9;22)	Stable for many yr (most cases)
CMML	Median, 65-75 yr, M > F	Monocytosis >1000, cytopenias, myeloid dysplasias, <20% blasts	+8, –7, 12p abnormalities in 20%-40% of cases; negative t(9;22)	20-40 mo with progression to AML in 15%-30%
JMML	Younger than 3 yr, M > F	Monocytosis >1000, blasts <20%, plus two of ↑Hb F, immature granulocytes, WBC >10K, clonal abnormalities, GM-CSF hypersensitivity	Monosomy 7, negative t(9;22)	Poor; possible benefit from BMT
Myeloid/lymphoid neoplasms w/↑eos and *PDGFR/FGFR1*	M 25-55 yr	PB w/inc eos, BM eos with mast cells	*FIP1L1-PDGFRA, PDGFRB, FGFR*	Variable response to TKI
Mastocytosis	All ages	Mononuclear w/central nuclei, variable basophilic granules (often not seen in fixed tissue); dense aggregates of spindle cells	*KIT* D816V	Cutaneous, indolent; systemic, variable; leukemia, aggressive
CEL NOS, idiopathic HES	Usually adult M; any age or sex	PB ≥1.5 K eos/μL, <20% blasts	+8, i(17q) 8p11 w/various partners	Indolent, 80% 5-yr survival

AML, Acute myelogenous leukemia; *BM,* bone marrow; *BMT,* bone marrow transplant; *CEL,* chronic eosinophilic leukemia; *CIM,* chronic idiopathic myelofibrosis; *CML,* chronic myeloid leukemia; *CMML,* chronic myelomonocytic leukemia; *CNL,* chronic neutrophilic leukaemia; *eos,* eosinophils; *EPO,* erythropoietin; *ET,* essential thrombocythemia; *F,* female; *GM-CSF,* granulocyte-macrophage colony-stimulating factor; *Hb,* hemoglobin; *HES,* hypereosinophilic syndrome; *inc,* increased; *JMML,* juvenile myelomonocytic leukemia; *LD,* lactate dehydrogenase; *M,* male; *MDS,* myelodysplastic syndrome; *NAP,* neutrophil alkaline phosphatase; *NOS,* not otherwise specified; *PB,* peripheral blood; *PMF,* primary myelofibrosis; *PV,* polycythemia vera; *TKI,* tyrosine kinase inhibitor; *WBC,* white blood cell.
From McPherson RA, Pincus MR: *Henry's clinical diagnosis and management by laboratory methods,* ed 23, Philadelphia, 2017, Elsevier.

- Chromosomes, either by FISH or conventional cytogenetics
- Molecular testing in peripheral blood for *BCR-ABL* (rule out chronic myeloid leukemia), *JAK2,* calreticulin, and *MPL* mutations for risk stratification. Distinguishing calreticulin type I vs. type II has clinical relevance for risk stratification
- Additional mutation testing for *ASXL1* or *SRSF2* if available

Rx TREATMENT

Prognostic scoring systems for primary myelofibrosis are summarized in Table E5. The Dynamic International Prognostic Scoring System plus (DIPSS-plus) identifies several risk factors for survival and leukemic transformation.

- Age >65 yrs
- Hemoglobin <10 g/dl
- Leukocyte count >25 × 10^9/L
- Circulating blasts >1%
- Presence of constitutional symptoms
- Red cell transfusion need
- Platelet <100 × 10^9/L
- Unfavorable karyotype (complex or presence of +8, –7/7q–, i(17q), inv(3), –5/5q–, 12p–, or 11q23 rearrangement)

Risk scoring:

- Low (zero risk factors);
- Intermediate-1 (one risk factor);
- Intermediate-2 (two or three risk factors), and
- High (greater than four risk factors).

Median survivals (Table E6) are as follows: low, 185 mo; INT-1, 78 mo; INT-2, 35 mo; high, 16 mo. Molecular correlates for survival independent of DIPSS plus have recently been identified, based on the presence/absence of calreticulin mutation type I and *ASXL1*. For *CALR+/ASLX1* patients, median survival is 10.5 yr; for *CALR–/ASXL+* survival was 2.3 yr; for patients with both or neither mutations, survival was 5.8 yr.

LOW AND INTERMEDIATE 1 RISK

- Asymptomatic—observation
- Conventional drug therapy if symptomatic (response rates to each of the following agents is ~15% to 25%):
  1. Anemia—androgens (e.g., oxymetholone), danazol, prednisone, lenalidomide or thalidomide +/– prednisone, erythroid-stimulating agents in some cases.

TABLE E5 Prognostic Scoring Systems for Primary Myelofibrosis

Risk Factor	Lille	IPSS	DIPSS	DIPSS Plus
Anemia (hemoglobin)	X (<10 g/dl)	X (<10 g/dl)	X (<10 g/dl)	X (<10 g/dl)
Leukocytosis (white blood cell count)	X (<4 or >30 × 10^9/L)	X (>25 × 10^9/L)	X (>25 × 10^9/L)	X (>25 × 10^9/L)
Peripheral blood blasts		X (≥1%)	X (≥1%)	X (≥1%)
Constitutional symptoms		X	X	X
Age (yrs)		X (>65)	X (adjusted for age)	X
Karyotype				X (unfavorable[a])
Platelet				X (<100 × 10^9/L)
Transfusion status				X

[a]Unfavorable karyotype includes complex or sole or two abnormalities that include +8, −7/7q−, i7/7q−, i(17q), −5/5q−, 12p−, inv(3), or 11q23 rearrangements.
DIPSS, Dynamic international prognostic scoring system; *IPSS,* international prognostic scoring system.
From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E6 Median Survival of Each Risk Group in Four Prognostic Scoring Systems for Primary Myelofibrosis

Risk Group	Lille	IPSS	DIPSS	DIPSS Plus
Low	93 mo	135 mo	Not reached	185 mo
Intermediate-1	26 mo	95 mo	170 mo	78 mo
Intermediate-2		48 mo	48 mo	35 mo
High	13 mo	27 mo	18 mo	16 mo

DIPSS, Dynamic international prognostic scoring system; *IPSS,* international prognostic scoring system.
From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E7 Relationship of Mutation Profile to Survival in Primary Myelofibrosis

Mutation	Incidence (%)*	Median Survival (yr)
JAK-2 V617F	60	5.9
CALR exon 9	21	15.9
"Triple negative"	12	9.9
MPL	6	2.3

*Based on 428 patients from Mayo Clinic, Bergamo and Florence, Italy.
Data from Tefferi A et al: Long-term survival and blast transformation in molecularly annotated essential thrombocythemia, polycythemia vera, and myelofibrosis, *Blood* 124(16):2507-2513, 2014.

2. Lenalidomide response rates are higher if a 5q deletion is present.
3. Symptomatic splenomegaly—hydroxyurea (first line, helpful in about 40%), ruxolitinib, splenectomy.
4. Radiation offers transient palliation of splenic symptoms; treatment of choice for extramedullary hematopoiesis.

- Lower-risk patients who are positive for *ASXL1* or *SRSF2* should be considered for allogeneic transplant. Patients with these mutations have a median time to leukemic transformation of 5.6 yr, vs. 18 yr for those who do not have them.

INTERMEDIATE 2 AND HIGH RISK

- High-risk genetics include *ASLX1* and *SRSF2* mutations and absence of calreticulin mutations or "triple-negative" status.
- Allogeneic stem cell transplant is recommended for eligible, higher-risk patients but the timing is controversial. In a recent report from the European Society for Blood and Marrow Transplantation, for patients who were 2-yr survivors after undergoing allogeneic hematopoietic stem cell transplant, the overall survival was 74% at 10 yr. Excess mortality was 14% and 33% in patients aged <45 yr and patients aged ≥65 yr, respectively.
- Ruxolitinib is an inhibitor of Janus-associated kinases *JAK1* and *JAK2.* Survival benefit is suggested by longer follow-up, especially in symptomatic patients. Approximately 50% remain responsive to ruxolitinib at 5 yr.
- Splenectomy, especially for transfusion-dependent anemia or severe thrombocytopenia.

DISPOSITION

- Median survivals according to DIPSS plus risk groups are: low, 185 mo; INT-1, 78 mo; INT-2, 35 mo; high, 16 mo.
- Median survival based on genomic analysis (Table E7):
  1. *CALR* mutated 17.7 yr; *JAK2* mutated 9.2 yr; *MPL* mutated 9.1 yr; triple-negative 3.2 yr
- Molecular correlates for survival independent of DIPSS plus have recently been identified based on the presence/absence of CALR mutation type I and *ASXL1* mutation.
  1. *CALR+/ASLX1−* patients: median survival 10.5 yr
  2. *CALR−/ASXL+*, median survival 2.3 yr
  3. For patients with both or neither mutations, survival was 5.8 yr.

PEARLS & CONSIDERATIONS

- PMF entails a wide spectrum of prognosis according to numerous risk factors.
- The only curative treatment is allogeneic stem cell transplant, which entails high risk of treatment-related mortality and morbidity.

Primary Ovarian Insufficiency

BASIC INFORMATION

DEFINITION

- Women younger than 40 yr of age with amenorrhea, oligomenorrhea, or dysfunctional uterine bleeding for 4 mo or more along with follicle stimulating hormone (FSH) levels in the menopausal range meet diagnostic criteria for primary ovarian insufficiency.
- Menopause younger than the age of 40 yr.

SYNONYMS

POI
Hypergonadotropic hypogonadism
Premature ovarian failure
Premature menopause
Gonadal dysgenesis

ICD-10CM CODES

E28.3	Primary ovarian failure
E28.310	Symptomatic premature menopause
E28.39	Other primary ovarian failure
E28.9	Ovarian dysfunction, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Affects 1% to 4% of the female population in the U.S.
PREDOMINANT AGE: 1:250 incident cases by age 35 and 1:100 by age 40

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The most common presentation is disturbance in menstrual pattern due to intermittent ovarian function.
- Between 5% and 30% of affected women have another affected female relative.
- Between 10% and 30% of affected women already have a concurrent autoimmune condition, the most common of which is hypothyroidism.
- Symptoms of estrogen deficiency include hot flashes, night sweats, poor concentration, drying of the vagina, and infertility.
- Physical exam may reveal stigmata of an autoimmune condition such as vitiligo, thyroid enlargement, or Turner syndrome (webbed neck, short stature, and high-arched palate).

ETIOLOGY (SEE TABLE 1)

Idiopathic in 95% of cases

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pregnancy.
- Causes of secondary amenorrhea include eating disorder, exercise, drugs, sarcoidosis, polycystic ovarian disease, hypothalamic amenorrhea, hyperprolactinemia/prolactinoma, and Cushing disease.

WORKUP

- After pregnancy is ruled out, the initial evaluation should include the measurement of serum prolactin, FSH, and thyrotropin (TSH) levels.
- If the FSH level is in the menopausal range (>40 μIU/ml by radioimmunoassay), the test should be repeated in 1 mo along with a serum estradiol measurement to confirm the diagnosis of primary ovarian insufficiency.

LABORATORY TESTS

Once a diagnosis of premature ovarian failure is made, other evaluations include:

- Autoimmune disorders, adrenal insufficiency (seen in 3% of cases): Serum anti-adrenal and anti-21 hydroxylase antibodies should be measured.
- Hypothyroidism: Serum TSH, T_4, and anti-TPO antibodies.
- All cases should be screened for osteoporosis by DXA for bone mineral density.
- A karyotype analysis should be performed for all patients to look for chromosomal defects including Turner variant or deletions of the X chromosome.
- Permutations for the fragile X syndrome (*FMR1* gene) should be checked for as well.

IMAGING STUDIES

Pelvic ultrasound has no proven benefit in the management of these patients.

TREATMENT

NONPHARMACOLOGIC THERAPY

Counseling or patient support group should be offered to all women with low self-esteem and depression due to the psychological scar left by the diagnosis.

ACUTE GENERAL Rx

- Physiologic estrogen and progestin replacement is reasonable in the cases of young women until they reach the age of natural menopause.
- A dose of 100 mcg of estradiol per day, administered by transdermal patch, achieves average estradiol level observed in normal menstruating women and effectively treats symptoms.
- Cyclic medroxyprogesterone at a dose of 10 mg per day for 12 days each month is the preferred progestin to provide protection against endometrial cancer.
- Pregnancy may occur while a woman is taking estrogen and progesterone therapy and the therapy should be stopped immediately if the pregnancy test is found to be positive.

TABLE 1 Mechanisms and Causes of Primary Ovarian Insufficiency

Accelerated Follicular Depletion

Genetic: Turner syndrome, fragile X premutations, galactosemia
Toxic: Chemotherapy, radiation, infections such as mumps or cytomegalovirus
Autoimmune: Polyglandular failure, hypothyroidism, Addison disease, vitiligo, myasthenia gravis

Abnormal Follicular Stimulation

Gonadotropin receptor function: Follicle stimulating hormone/luteinizing hormone receptor mutation
Enzyme defects: Aromatase deficiency, luteinized follicles

CHRONIC Rx

- Intake of 1200 mg of elemental calcium and 800 units of vitamin D_3 per day should be encouraged to prevent bone loss. A serum 25-hydroxyvitamin D level of 30 ng per ml or higher should be maintained.
- Patients with positive tests for adrenal antibodies should be evaluated annually for adrenal insufficiency by corticotropin stimulation test.
- Patients who wish to avoid pregnancy should use a barrier method or an IUD.
- Options for parenthood include adoption, foster parenthood, egg donation, and embryo donation.

DISPOSITION

Women with the known diagnosis should be encouraged to maintain a lifestyle that optimizes bone and cardiovascular health, including regular weight-bearing exercises, adequate intake of calcium (1200 mg daily) and vitamin D (800 IU daily), healthy diet to prevent obesity, and screening for cardiovascular risk factors.

REFERRAL

Referral to gynecologist and reproductive endocrinologist may be helpful in patients who decide to pursue parenthood.

PEARLS & CONSIDERATIONS

COMMENTS

- Common etiologies should be ruled out, including chromosomal abnormalities, fragile X premutations, and autoimmune causes.
- Management directed at symptom resolution and bone protection primarily, but should include psychosocial support for women facing this devastating diagnosis.

PREVENTION

Early diagnosis of primary ovarian insufficiency important for osteoporosis prevention and possibly prevention of coronary artery disease.

Amenorrhea (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Primary sclerosing cholangitis (PSC) is an autoimmune fibroinflammatory disease predominantly affecting the large bile ducts. It is characterized by segmental fibrosing and inflammation of intrahepatic and extrahepatic bile ducts complicated by recurrent cholangitis, cholangiocarcinoma (CCA), cirrhosis, and portal hypertension.

SYNONYMS

Chronic obliterative cholangitis
Fibrosing cholangitis
Stenosing cholangitis
PSC

ICD-10CM CODES
K83.0 Cholangitis
K83.9 Disease of biliary tract, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- The incidence and prevalence of PSC are 0.9 to 1.3 cases per 100,000 persons per yr and 8.5 to 16.2 cases per 100,000 persons, respectively.
- About 65% of patients with PSC are men.
- Mean age of presentation is 30 to 40.
- Over 80% of patients with PSC also have inflammatory bowel disease (IBD). 4% to 5% of patients with ulcerative colitis (UC) will develop PSC. A PSC-IBD phenotype may be present which carries a higher risk of colon cancer and is characterized by mild pancolitis, rectal sparing, and backwash ileitis. PSC is an independent risk factor for developing colon cancer in patients with IBD.
- PSC can coexist with other autoimmune liver diseases. Autoimmune hepatitis (AIH) and PSC overlap syndrome can be seen and is more common in young adults and children.
- Cholangiocarcinoma is present in 1% to 2% of PSC patients at diagnosis and should be considered a premalignant disease. The lifetime risk is 5% to 10%.
- Box 1 summarizes a classification of and diseases associated with sclerosing cholangitis.
- The median survival from time of diagnosis is 10 to 15 yr without liver transplantation.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Many patients are asymptomatic (up to 50%) at the time of diagnosis with normal physical examination findings. However, many patients will have abnormal liver tests and a known diagnosis of IBD.
- More than 75% of asymptomatic patients develop symptoms, the most common of which are nonspecific pruritus, abdominal pain, and fatigue. Physical findings of symptomatic patients may reveal jaundice, skin excoriation and hyperpigmentation from scratching, hepatosplenomegaly, and xanthelasma. Other symptoms include steatorrhea and weight loss, which are concerning for advanced PSC, sepsis, or mechanical obstruction (i.e., cholangitis), and malignancy (i.e., cholangiocarcinoma).
- Patients can also present with advanced liver disease and decompensated cirrhosis (i.e., ascites, spontaneous bacterial peritonitis, hepatic encephalopathy, and variceal hemorrhage) or hepatic failure. In patients with cirrhosis, physical findings may reveal a shrunken nodular liver and evidence of portal hypertension.

ETIOLOGY

- The cause of PSC is unknown, but the most likely mechanism is immunologic priming in a genetically susceptible patient causing phenotypic expression of PSC.
- Genetic and immunologic factors are supported by reports of familial occurrence of this disorder and increased frequency of HLA B8 and DR3. Genome-wide association studies have discovered novel loci associated with PSC, but the functional aspects of these genes are still unknown.
- Portosystemic inflammation caused by translocation of the gut microbiota is an increasing area of research. The close association with UC and PSC may be secondary to gut-activated T lymphocytes in IBD causing portal inflammation because of overlapping adhesion molecules in the gut and liver. Furthermore, intestinal dysbiosis in PSC has also been seen and remains an area of ongoing research.
- Dysregulated inflammatory cytokine production by cholangiocytes is also more recently suggested to be playing a role in the pathogenesis of PSC.

DIAGNOSIS

Diagnosis is based on characteristic cholangiographic findings in combination with clinical, biochemical, and in some cases histologic features. It is increasingly common to diagnose PSC based on imaging with magnetic resonance cholangiopancreatography (MRCP). Liver biopsy is now rarely used to diagnose disease. Table 1 describes staging of PSC. Work is being done to enable a diagnosis to be made based on biomarkers such as microRNA and fecal microbiota profiles.

DIFFERENTIAL DIAGNOSIS

- IgG4-associated cholangitis (IAC)
- Surgical biliary trauma
- Ischemic cholangitis, recurrent pyogenic cholangitis, recurrent pancreatitis
- Choledocholithiasis, cholangiocarcinoma
- Intraarterial chemotherapy (5-FU/floxuridine)
- Diffuse intrahepatic metastasis, sarcoidosis, or amyloidosis
- AIDS-related, eosinophilic, or mast cell cholangiopathy
- Histiocytosis X, graft-versus-host disease
- Hepatic inflammatory pseudotumor, portal hypertensive biliopathy

WORKUP

History, physical examination, laboratory evaluation, and imaging studies (MRCP). Liver biopsy is generally not necessary for diagnosis

LABORATORY TESTS

- Serum biochemical tests are abnormal in approximately 75% of patients with PSC, with a predominantly cholestatic pattern and an elevation in the serum alkaline phosphatase (3-10 times the upper limit of normal for more than 6 mo). However, this value can vary and be normal during the disease course. Serum aminotransferase levels are elevated in the majority of patients (2-3 times the upper limits of normal). Serum bilirubin is usually normal at the time of diagnosis unless the patient has advanced stricturing disease; an initial elevation of bilirubin at diagnosis may be related to worse prognosis.
- A wide range of autoantibodies can be detected in patients with PSC; however, they are nonspecific for PSC, including the perinuclear antineutrophil cytoplasmic antibody (pANCA), autoantibodies such as antinuclear antibody (ANA), and anti-smooth muscle antibody (ASMA).
  1. Perinuclear antineutrophil cytoplasmic antibody (pANCA) is positive in 33% to 88% of those with PSC but is not specific.
  2. Anti-mitochondrial antibody (AMA), which is characteristic of primary biliary cholangitis (PBC), is *NOT* found in PSC and can be helpful in excluding PSC.
  3. Serum IgG levels are useful in the diagnosis of PSC-AIH overlap syndrome (more common in pediatric patients) and IAC with autoimmune pancreatitis.
  4. In particular, elevated levels of IgG4 are found in 10% to 20% of PSC patients, with a subset of these patients displaying features of autoimmune pancreatitis. PSC patients with elevated IgG4 tend to have worse outcomes and seem to respond to corticosteroid therapy; hence, IgG4 levels should be checked at least once in all patients with PSC.

IMAGING STUDIES

- Cholangiography (Fig. E1), with magnetic resonance cholangiopancreatography (MRCP) or endoscopic retrograde cholangiopancreatography (ERCP), is considered to be the gold standard for the diagnosis of PSC. Characteristic findings reveal segmental fibrosis of bile ducts with saccular dilatation of normal intervening areas resulting in a "beads-on-a-string" appearance.
- MRCP has an overall diagnostic accuracy rate of 90%. It is the first imaging modality of choice when PSC is suspected because ERCP can be associated with increased rates of serious complications (i.e., pancreatitis and cholangitis) in patients with PSC.
- Liver biopsy is not necessary for the diagnosis of PSC in patients with typical cholangiographic findings. Biopsies are subject to sample variation, and typical "onion skin"–type periductal fibrosis is rare. Liver biopsy

BOX 1 Classification of and Diseases Associated with Sclerosing Cholangitis

Primary Sclerosing Cholangitis
Principal Disease Associations
Inflammatory bowel disease:
- Crohn colitis or ileocolitis
- Ulcerative colitis

Other Disease Associations
Systemic diseases with fibrosis:
- Inflammatory pseudotumor
- Mediastinal fibrosis
- Peyronie disease
- Pseudotumor of the orbit
- Retroperitoneal fibrosis
- Riedel thyroiditis

Autoimmune or collagen vascular disorders:
- Autoimmune hemolytic anemia
- Celiac disease
- Chronic sclerosing sialoadenitis
- Membranous nephropathy
- PSS
- Rapidly progressive glomerulonephritis
- RA
- Sjögren syndrome
- SLE
- Type 1 diabetes mellitus

Alloimmune diseases:
- Hepatic allograft rejection
- Hepatic graft-versus-host disease after bone marrow transplantation

Infiltrative diseases:
- Hypereosinophilic syndrome
- Histiocytosis X
- Sarcoidosis
- Systemic mastocytosis

Immunodeficiency:
- Congenital immunodeficiency
  - Combined immunodeficiency
  - Dysgammaglobulinemia
  - X-lined agammaglobulinemia
- Acquired immunodeficiency:
  - AIDS
  - Angioimmunoblastic lymphadenopathy
  - Opportunistic infections (e.g., cryptosporidiosis, cytomegalovirus, microsporidiosis)
  - Selective IgA deficiency

Secondary Sclerosing Cholangitis
Obstructive
Autoimmune pancreatitis
Biliary parasites
Caroli disease
Choledocholithiasis
Chronic pancreatitis
Congenital abnormalities:
- CF
- Choledochal cyst

Fungal infection
Recurrent pyogenic cholangitis
Surgical stricture

Toxic
Intra-arterial floxuridine (FUDR)
Intraductal formaldehyde or hypertonic saline (echinococcal cyst treatment)

Ischemic
Hepatic allograft arterial occlusion
Paroxysmal nocturnal hemoglobinuria
Toxic vasculitis (FUDR)
Vascular trauma

Neoplastic
Cholangiocarcinoma
Hepatocellular carcinoma
Lymphoma
Metastatic cancer

AIDS, Acquired immunodeficiency syndrome; *CF,* cystic fibrosis; *FUDR*, 5-fluorouracil deoxyribonucleoside; *Ig,* immunoglobulin; *PSS,* progressive systemic sclerosis; *RA,* rheumatoid arthritis; *SLE,* systemic lupus erythematosus.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

may help in the diagnosis of PSC-AIH overlap syndrome, small-duct PSC (normal cholangiogram), or IAC.
- Noninvasive measurements of liver elastography including MR elastography are promising methods for evaluating for cirrhosis but have not yet been validated in this patient cohort.

Rx TREATMENT

- No medical therapy has been established to be effective in halting the disease progression of PSC. Liver transplantation is indicated in patients with decompensated cirrhosis, hilar cholangiocarcinoma, and in those with recurrent bacterial cholangitis.
- Ursodeoxycholic acid (UDCA) has shown variable benefit in randomized controlled trials.
- Although biochemical improvement has been seen with UDCA, there has been no proven benefit on survival.
- In two trials, high-dose UDCA (28-30 mg/kg/day) was associated with colorectal dysplasia, liver transplantation, and varices. Therefore, high-dose UDCA is *NOT* universally recommended as medical therapy in patients with PSC. A trial of medium- or low-dose UDCA ~20 mg/kg/day is used by some clinicians, since some trials have shown biochemical response.
- Oral vancomycin may show clinical and biochemical response in pediatric patients, but no randomized clinical trial has been performed. The benefit seen from the use of oral vancomycin may be related to the antibiotic effect on the microbiome of the gut. Investigations are ongoing.
- Manipulation of the microbiome is an exciting area being explored as a future treatment for PSC. Recent studies have shown that FMT in PSC is safe, improves liver biochemistries, and improves microbiome diversity. This is a rapidly expanding area of gastroenterology that shows promise. However, larger studies are needed to determine if such treatments can affect mortality or reduce liver transplantation.
- The use of corticosteroids and other immunosuppressive agents is not recommended in patients with PSC alone; however, it is recommended in patients with PSC-AIH overlap syndrome or elevated IgG4.
- Use of tumor necrosis factor inhibitors has been ineffective in PSC. Other monoclonal antibody therapies targeting lymphocyte trafficking, tyrosine kinase signaling, and liver fibrosis are being studied. Furthermore, other targets for treatment are ongoing and aimed at bile acid synthesis and mast cell inhibition.
- Bile acid–based therapeutic approaches are currently in clinical trials, including peroxisome proliferator-activated receptor agonists and farnesoid X receptor agonists.
- Management of PSC patients is aimed at symptom relief and management of complications from PSC (i.e., obstruction/strictures, cirrhosis, portal hypertension).

TABLE 1 Staging of Primary Sclerosing Cholangitis

Stage	Description
I—Portal	Portal edema, inflammation, ductal proliferation; abnormalities do not extend beyond the limiting plate
II—Periportal	Periportal fibrosis with or without inflammation extending beyond the limiting plate
III—Septal	Septal fibrosis, bridging necrosis, or both
IV—Cirrhotic	Biliary cirrhosis

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, WB Saunders.

ACUTE GENERAL Rx

- With mild pruritus, skin emollients and antihistamines are recommended as the first-line treatment.
- With moderate or severe pruritus, bile acid sequestrants (i.e., cholestyramine 16 g/day) are the preferred choice for the initial management of pruritus. Alternative agents for pruritus refractory to bile acid sequestrants include rifampicin 150 to 300 mg twice daily, naltrexone 50 mg daily, sertraline 75 to 100 mg daily, or phenobarbital 90 mg at bedtime.
- Patients who present with increasing serum bilirubin and/or worsening pruritus, progressive bile duct dilation on imaging studies, or cholangitis need to be evaluated for dominant strictures with imaging. A dominant stricture is a stenosis <1.5 mm in the common bile duct or <1 mm in the hepatic duct.
- ERCP with brushings, cytology, and fluorescent in situ hybridization (FISH) is recommended to evaluate dominant strictures for cholangiocarcinoma, which is found in 15% to 20% of cases. Once malignancy is excluded, balloon dilation with or without stenting is recommended to treat symptoms. Routine stenting is not required, but short-term stenting may be helpful in patients with severe stricture. If ERCP is unsuccessful, percutaneous cholangiopancreatography with stenting should be considered.
- In noncirrhotic patients with dominant strictures refractory to endoscopic or percutaneous management, surgery should be considered, although this may complicate future liver transplantation surgery.
- Antibiotic usage is recommended in patients with dominant strictures/obstructions both acutely and for long-term prophylaxis in patients with recurrent cholangitis.

CHRONIC Rx

- Avoidance of alcohol and vaccination against hepatitis A and B is advised.
- Patients with PSC are at risk for osteoporosis and osteopenia.
  1. The pathophysiology of bone loss is poorly understood but likely multifactorial. Impaired absorption of fat-soluble vitamins, such as vitamins D and K, and possible impairment of osteoblasts by bilirubin may be contributing factors. The risk of osteoporosis appears to be independent of cumulative corticosteroid exposure.
  2. DEXA scan should be performed at diagnosis and should be repeated in 2 to 4 yr.
  3. Calcium (1000-1500 mg) and vitamin D 600 to 800 IU daily are recommended for patients with osteopenia, and the addition of bisphosphonate is recommended in patients with osteoporosis.
- Patients with newly diagnosed PSC should have a full colonoscopy with biopsies to exclude concurrent IBD and for surveillance of colorectal cancer. In patients with IBD, continued surveillance colonoscopy with biopsies, or chromoendoscopy, at 1- to 2-yr intervals is recommended. In patients without IBD, a suggested 3- to 5-yr surveillance interval has been recommended due to an increased risk of colorectal cancer.
- Cholangiocarcinoma (CCA) development is common in PSC. Surveillance for CCA should be performed every 6 to 12 mo with ultrasound, CT, or MRI, with or without serum CA 19-9. Although CA19-9 may detect CCA, Sinakos et al[1] evaluated the long-term outcomes in patients with PSC and increased levels of CA 19-9 and found that one third of patients did not have CCA after 30 mo of follow-up. These differences may in part be due to genotypic differences in *FUT2/3* alleles that affect expression of CA19-9. Surveillance is not indicated in PSC patients <20 yr of age or those who have small duct PSC. Endoscopic retrograde cholangiopancreatography (ERCP) with brush cytology or cholangioscopy should be performed in patients who have biochemical or symptomatic deterioration or dominant stricture.
- Annual transabdominal ultrasound is recommended due to the increased risk of gallbladder malignancy, even in patients who are not cirrhotic. If masses or polyps >8 mm are detected, cholecystectomy should be performed.
- Patients with PSC and cirrhosis are recommended to have hepatocellular carcinoma (HCC) surveillance with ultrasound, with or without α-fetoprotein, every 6 mo and gastroesophageal variceal surveillance at regular intervals.
- With advanced disease, fat-soluble vitamin deficiencies such as A, E, and D should be assessed.
- In cases of HCC and CCA, depending on underlying liver disease, resection versus liver transplantation would be required.

[1]Sinakos E et al: Many patients with primary sclerosing cholangitis and increased serum levels of carbohydrate antigen 19-9 do not have cholangiocarcinoma, *Clin Gastroenterol Hepatol* 9:434-439, 2011, e1.

DISPOSITION

Liver transplantation is the only effective treatment for patients with end-stage liver disease, portal hypertension, liver failure, and recurrent or intractable bacterial cholangitis. Survival is excellent, with 90% and 80% survival rates at 1 and 5 yr, respectively. The recurrence of PSC after transplant is reportedly 5% to 20%. Transplant referral is warranted when MELD exceeds 14 or greater, or with worsening cholangitis or intractable pruritus.

REFERRAL

Gastroenterology and/or hepatology for treatment of PSC, management of its complications, surveillance of associated malignancy, and evaluation for liver transplantation.

PEARLS & CONSIDERATIONS

- Management of PSC targets symptom relief, complications of PSC, cirrhosis, early carcinoma detection, and timely referral for liver transplantation.
- High-dose UDCA is not universally recommended for treatment of PSC.
- Patients are at increased risk for the development of colorectal cancer, gallbladder cancer, and cholangiocarcinoma and need surveillance.
- Patients with PSC and ulcerative colitis have more common right-sided colon involvement and greater risk of pouchitis after colectomy with an ileal pouch-anal anastomosis.
- In patients with cirrhosis, surveillance for gastroesophageal varices and HCC is recommended.
- Liver transplant remains the only definitive therapy for complications of PSC.

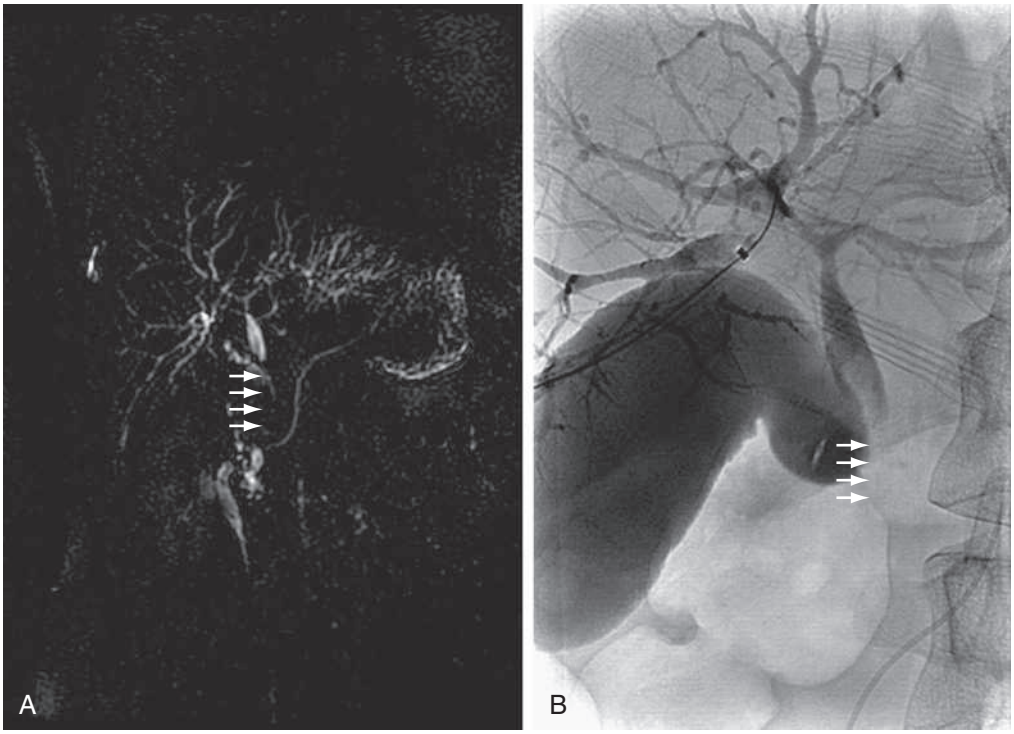

FIG. E1 A, Reconstructed magnetic resonance cholangiopancreatography images in a patient with primary sclerosing cholangitis. The intrahepatic biliary radicles are diffusely abnormal and characterized by pruning and a beaded appearance. There is a dominant stricture at the level of the distal bile duct *(arrows)* indicated by a signal void on magnetic resonance image. **B,** A percutaneous cholangiogram in the same patient. Note the high-grade, dominant, distal bile duct stenosis *(arrows)* with a markedly enlarged gallbladder, suggesting that the stricture involves the insertion of the cystic duct. Similar findings could be seen in a patient with a distal cholangiocarcinoma. (From Feldman M et al: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier)

Progressive Multifocal Leukoencephalopathy (PML)

BASIC INFORMATION

DEFINITION

Progressive multifocal leukoencephalopathy (PML) is an uncommon and often fatal subacute demyelinating disease of the white matter, caused by reactivation of the JC virus (JCV) infection, which has tropism for oligodendrocytes, in an immunocompromised individual. PML originally was described half a century ago by Astrom et al in patients with chronic lymphoid leukemia and Hodgkin lymphoma. JCV was isolated in 1971 and is named for the initials of the first patient from whose brain it was isolated.

SYNONYM

PML

ICD-10CM CODE

A81.2 Progressive multifocal leukoencephalopathy

EPIDEMIOLOGY & DEMOGRAPHICS

RISK FACTORS: Typically seen in patients with profound immunosuppression and impaired cell-mediated immunity. These include patients with AIDS, lymphoproliferative disorders, chronic infections such as tuberculosis, and, more recently, patients on immunosuppressive or immunomodulating medications such as natalizumab, rituximab, efalizumab, brentuximab vedotin, mycophenolate mofetil, anti-TNF-alpha agents, and oral agents used in the treatment of multiple sclerosis (dimethyl fumarate and fingolimod). In rare instances, it may be seen in the absence of apparent immunologic abnormality.

INCIDENCE AND PREVALENCE:

- The PML era can be broadly divided into four epochs: Pre-HIV, HIV (pre-ART), HIV (post-ART), and modern era.
- Prior to the HIV epidemic in the early 1980s, PML was rare and seen almost exclusively in patients with lymphoproliferative and myeloproliferative disorders.
- HIV: A fiftyfold increase in PML cases was reported with HIV epidemic. During the HIV pre-highly active antiretroviral therapy (HAART) era, 3% to 5% of patients with HIV developed PML. PML is an AIDS-defining illness. Highly active retroviral therapy (ART) has led to some decline in PML cases.
- Incidence of PML in natalizumab-treated patients depends on treatment duration. Incidence is 7.4/1000 without prior immunosuppressant use and 19.5/1000 with prior immunosuppressant use during mos 25 to 48.
- Seroepidemiologic studies have shown that asymptomatic primary infection with JCV occurs at an early age, and by adult life 30% to 90% of the population is seropositive. It becomes dormant in tissues such as kidney, bone marrow, tonsils, and lymphoreticular tissue.

PREDOMINANT SEX AND AGE: Males and females are equally affected. There is no specific age distribution.

GENETICS: Unknown

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Subacute neurologic deficits are common; can also present acutely as a stroke mimic.
- The clinical course spans wks to mos leading to severe disability and death.
- PML lesions usually involve cerebral hemispheres; cerebellar and brainstem involvement may be seen in AIDS. Multifocal asymmetric white matter involvement is common; rarely there can be gray matter involvement including cerebellar granular cells. Usually the optic nerve and spinal cord are not involved.
- Non–AIDS-associated PML: Early lesions involve occipital subcortical white matter and cause visual-field deficits (homonymous hemianopia) or cortical blindness. Motor weakness and altered mentation may be seen, while headache, seizures, and extrapyramidal syndromes are rare.
- AIDS-related PML: Motor weakness is more common. Abnormalities of speech, cognition, gait, sensation, and visual impairment are also seen.
- Natalizumab-associated PML: Frontal lobe is commonly involved, leading to cognitive impairment, neurobehavioral changes, motor disorders, language disorders, and visual defects.
- Immune reconstitution inflammatory syndrome (IRIS): A paradoxical clinical deterioration that occurs during immunologic recovery in previously immunocompromised patients, such as antiretroviral therapy–treated HIV-seropositive patients or cessation of immunomodulating treatment, such as natalizumab. An increase in the number or size of lesions on neuroimaging with contrast enhancement of brain lesions and brain edema may be seen.

ETIOLOGY & PATHOGENESIS

- JCV infection may be acquired through respiratory tissue or oropharyngeal route; seroconversion usually occurs in childhood.
- A cytotoxic-specific response against JCV acts as a containing mechanism for PML. Immunosuppression leads to development of PML either as primary infection of the CNS following immunosuppression or reactivation of a dormant infection. The virus produces lytic infection of the oligodendrocytes and causes oligodendrocyte death and demyelination. Neuronal infection does not usually occur except in granule cell neurons of the cerebellum. Infection of the astrocytes is abortive, leading to characteristic bizarre enlarged cells.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Multiple sclerosis
- Acute disseminated encephalomyelitis
- Vasculitis
- HIV encephalitis
- Mitochondrial encephalopathies (e.g., mitochondrial encephalopathy, lactic acidosis, and stroke-like episodes [MELAS])
- Posterior reversible encephalopathy syndrome

WORKUP

- Diagnosis is based on compatible clinical presentation, MRI brain features, and detection of JCV in cerebrospinal fluid (CSF).
- The two diagnostic approaches employed include:
  1. Demonstration of typical histopathologic findings (multifocal demyelination, enlarged bizarre astrocytes with lobulated hyperchromatic nuclei, and enlarged oligodendroglial nuclei) and JC virus in tissue specimen (electron microscopy, immunohistochemistry, or polymerase chain reaction [PCR] techniques); or
  2. Demonstration of JC virus in the CSF of patients who fulfill clinical and radiographic criteria.

LABORATORY TESTS

- CSF examination: Usually normal; may show mild lymphocytic pleocytosis (20 to 25 leukocytes/ml) and elevated protein (usually <65 mg/dl).
- CSF PCR for JCV has a sensitivity of 95% and specificity of 99% using ultrasensitive PCR techniques, but may be lower depending on the techniques used.

IMAGING STUDIES

- MRI brain (Fig. E1) is the neuroimaging of choice and shows demyelinating lesions that are hyperintense on T2 and fluid-attenuated inversion recovery (FLAIR) sequences, are hypointense on T1, and typically don't enhance with gadolinium in patients with AIDS unless associated with IRIS. However, in drug-related PML, contrast enhancement is more likely to occur and may be related to IRIS from medication withdrawal.
- CT head may show subcortical hypodensities.
- MR spectroscopy will demonstrate features of demyelination—decreased *N*-acetyl acetate, increased choline, and increased lactate.

TREATMENT

There is no specific treatment for PML. Treatment is aimed at reversal of the underlying causes of immunosuppression.

NONPHARMACOLOGIC THERAPY

Plasma exchange and immunoadsorption for natalizumab-treated patients to rapidly reduce blood levels of natalizumab and hasten restoration of immune function. However, IRIS-related complications will need treatment, often with intravenous steroids.

ACUTE GENERAL Rx

- HIV-positive patients: Antiretroviral therapy should be optimized.
- HIV-negative patients: Immunosuppressive medication should be discontinued; plasma exchange may be considered for natalizumab-treated patients.
- IRIS: Treatment with steroids should be considered.

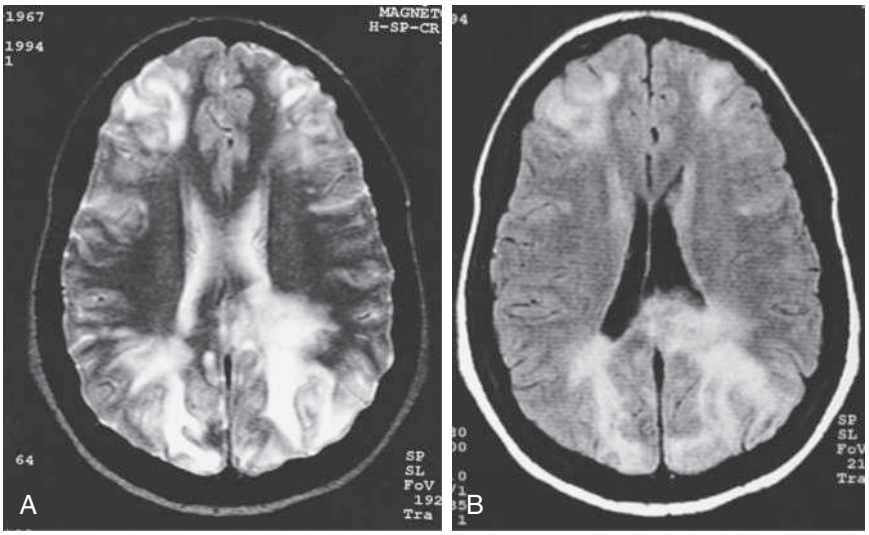

FIG. E1 Progressive multifocal leukoencephalopathy. Axial T2-weighted **(A)** and fluid-attenuated inversion recovery (FLAIR) **(B)** images of patient with human immunodeficiency virus (HIV). Multiple areas of white matter disease are identified; FLAIR image clarifies the involvement of periventricular white matter. These findings in an HIV-positive patient strongly suggest progressive multifocal leukoencephalopathy. (From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.)

SUGGESTED READINGS

Berger JR: The clinical features of PML, *Cleve Clin J Med* 2(78):S8-S12, 2011.

Cortese I et al: Pembrolizumab treatment for progressive multifocal leukoencephalopathy, *Engl J Med* 380(17):1597-1605, 2019.

Muftuoglu M et al: Allogeneic BK virus-specific T cells for progressive multifocal leukoencephalopathy, *N Engl J Med* 379(15):1443-1451, 2018.

Sahraian MA et al. Progressive multifocal leukoencephalopathy: a review of the neuroimaging features and differential diagnosis, *Eur J Neurol* 19(8):1060-1069, 2012.

CHRONIC Rx

No specific pharmacologic therapy exists for chronic treatment.

DISPOSITION

Of all HIV-related cerebral disorders, PML probably has the worst prognosis. Pre-AIDS era survival was 6 mo. With ART, incidence and prognosis of PML has improved. A lower CSF JCV load and better CD4 counts have better prognoses. Natalizumab-treated patients have worse prognoses seen with longer time to diagnosis, presence of widespread disease, and brainstem involvement.

REFERRAL

Refer to neurology if patients have neurologic deficits of uncertain etiology, especially in the setting of AIDS or immunosuppression.

PEARLS & CONSIDERATIONS

COMMENTS

PML is a fatal opportunistic cerebral infection that should be considered in all immunosuppressed individuals presenting with neurologic deficits and demyelinating cerebral lesions. Early referral to a center with neurologic expertise, especially neuroimmunology or neuroinfectious diseases, should be considered.

Progressive Supranuclear Palsy

BASIC INFORMATION

DEFINITION

Progressive supranuclear palsy (PSP) is an atypical parkinsonian syndrome characterized by supranuclear gaze impairment, prominent and early postural instability with falls, axial greater than appendicular rigidity, and poor or absent response to levodopa.

SYNONYMS

Steele-Richardson-Olszewski syndrome
Progressive supranuclear ophthalmoplegia
PSP

ICD-10CM CODES

G23.1 Progressive supranuclear ophthalmoplegia
G23.9 Degenerative disease of basal ganglia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1.1 per 100,000 (5.3 per 100,000 over age 50)
PREVALENCE: 4.9 per 100,000 (6.4 per 100,000 age-adjusted)
PREDOMINANT SEX AND AGE: Slight male predominance; mean age onset 65 yr, very uncommon for onset <50 yr
GENETICS: Familial cases have been reported only rarely. The vast majority of cases are sporadic.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Tremorless parkinsonism is the general clinical presentation, and differentiation from idiopathic Parkinson disease can be challenging early in the disease course. However, there are certain symptoms that can serve as "red flags" to consider PSP:

- Early postural instability and retropulsion leads to frequent falls; falls within the first yr of onset of symptoms is typically the rule.
- Supranuclear gaze palsy is often preceded by slowing of vertical saccades; square wave jerks may be present; blepharospasm is common.
- Dystonia of the frontalis and procerus muscles gives the PSP patient a "surprised" or "frightened" expression (Fig. E1) as opposed to the hypomimia of Parkinson disease (Fig. E2).
- Speech is typically strained, spastic, hypernasal, with a low-pitched dysarthria.
- Pseudobulbar affect and "emotional incontinence" can be seen, with easy crying or laughter.
- Early cognitive impairment, most commonly with apathy, disinhibition, and anxiety.

ETIOLOGY

PSP is caused by neuronal degeneration of nuclei in the brainstem and basal ganglia as a result of abnormal tau protein accumulation in tufted astrocytes and neurofibrillary tangles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Parkinson disease: Responds robustly to levodopa, progresses more slowly, starts asymmetrically, and lacks "red flag" symptoms listed previously.
- Corticobasal syndrome: Also a tauopathy like PSP, but parkinsonism is associated with prominent asymmetric dystonia, cortical sensory signs such as astereognosis, apraxia, and sometimes an "alien hand" syndrome.
- Multiple system atrophy: Distinguished by dysautonomia (particularly orthostatic hypotension), cerebellar ataxia, and inspiratory stridor.
- Dementia with Lewy bodies: A syndrome of coinciding dementia and parkinsonism, visual hallucinations, and fluctuating mental status.

WORKUP

- PSP is a clinical diagnosis, best made by a neurologist familiar with the disorder, such as a movement disorders specialist.
- A robust response to levodopa may lead consideration away from PSP.
- Brain MRI (see the following) can be helpful.

LABORATORY TESTS

There are no diagnostic laboratory tests.

IMAGING STUDIES

- Dorsal midbrain atrophy is commonly seen on MRI and is referred to as the "hummingbird sign" due to the elongated beak appearance seen on the midsagittal plane.
- Dopamine transporter imaging (DaTscan with [^{123}I]β-CIT SPECT) shows reduced uptake in PSP and is therefore not useful in differentiating PSP from Parkinson disease or other causes of parkinsonism.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Physical and occupational therapy are essential for avoiding the morbidity associated with frequent falls. Assistive devices such as a walker or wheelchair should be encouraged.

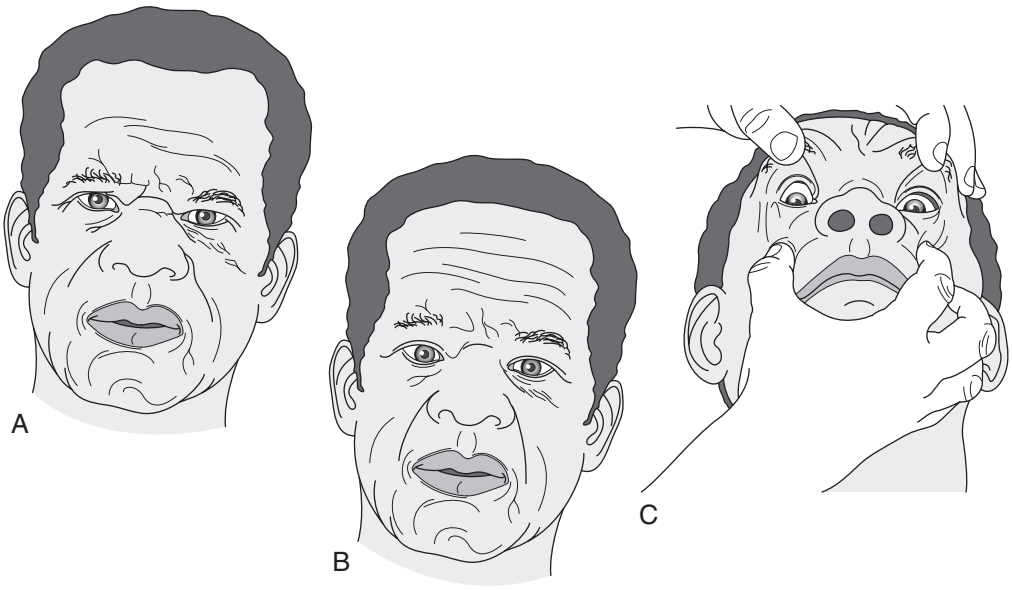

FIG. E1 A, PSP patients typically have a grimace because of continuous contractions of their facial muscles. **B,** Because of the loss of the ability to voluntarily move the eyes vertically, the hallmark of PSP, this patient cannot comply with the examiner's request to look downward. **C,** However, when the examiner rocks the patient's head back (performs an oculocephalic maneuver), his eyes dip well below the meridian. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

FIG. E2 A patient with progressive supranuclear palsy with staring expression, frontalis overactivity, and retrocollis. She is wearing a neck sling for a fractured wrist sustained in a fall. (From Burn D, Lees A: Progressive supranuclear palsy: where are we now? *Lancet Neurol* 1:359, 2002.)

- Dysphagia is a common finding that should be monitored closely in conjunction with a speech therapist.
- Prisms may be helpful to compensate for misalignment and diplopia resulting from the eye movement abnormalities; however, benefits, if noted, tend to be short-lived as the disease progresses.

CHRONIC Rx

- Although classically felt to be unresponsive to levodopa, there is often a transient but meaningful response to higher doses of levodopa (1200 mg/day). The poor response to levodopa is most likely due to the loss of postsynaptic dopamine receptors.
- Anticholinergic medications should be avoided.
- Blepharospasm can be effectively treated with botulinum toxin injections.

DISPOSITION

Median latency from symptom onset to wheelchair-bound state is 5 yr and to death is 7 yr in PSP-Richardson syndrome (classically described phenotype above). Lifespan improves to 10 to 12 yr in the PSP-parkinsonism. It is a closer clinical mimic to idiopathic PD and PSP-pure akinesia with gait freezing (no typical PSP features for first yrs, with freezing or gait, speech, and other activities being the primary manifestations) phenotypes.

REFERRAL

Referral to a movement disorders center is appropriate.

PEARLS & CONSIDERATIONS

COMMENTS

Consider PSP in a parkinsonian patient with the onset of falls within 1 yr of diagnosis, vertical eye movement abnormalities, early cognitive impairment, pseudobulbar affect, frontonasal dystonia, or poor response to levodopa.

PATIENT & FAMILY EDUCATION

Patient and caregiver information and resources can be found through CurePSP at www.psp.org.

Prolactinoma ALG PTG

BASIC INFORMATION

DEFINITION

Prolactinomas are monoclonal tumors that secrete prolactin.

ICD-10CM CODES

D35.2 Benign neoplasm of pituitary gland
E22.8 Other hyperfunction of pituitary gland

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Most common pituitary tumor; nearly 30% of all pituitary adenomas secrete enough prolactin to cause hyperprolactinemia
PREDOMINANT SEX: Microadenomas are more common in women; macroadenomas are found more frequently in men.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Men: Decreased facial and body hair, infertility, small testicles; may also have decreased libido, erectile dysfunction, and delayed puberty (caused by decreased testosterone as a result of inhibition of gonadotropin secretion).
- Women: Physical examination may be normal; history may reveal amenorrhea, galactorrhea (Fig. E1), oligomenorrhea, and anovulation.
- Both sexes: Visual field defects and headache may occur depending on size of tumor and its expansion.

ETIOLOGY

Prolactin-secreting pituitary adenomas: Microadenomas (<10 mm diameter) or macroadenomas (>10 mm diameter). No risk factors have been identified for sporadic prolactinomas. Rarely prolactinomas can be part of multiple endocrine neoplasia (MEN) type 1 syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Secretion of prolactin is under tonic inhibitory control by hypothalamic dopamine. Hyperprolactinemia may be caused by the following:

- Drugs: Risperidone, phenothiazines, methyldopa, reserpine, monoamine oxidase inhibitors, androgens, progesterone, cimetidine, tricyclic antidepressants, haloperidol, meprobamate, chlordiazepoxide, estrogens, narcotics, metoclopramide, verapamil, amoxapine, cocaine, oral contraceptives
- Hepatic cirrhosis, renal failure, primary hypothyroidism
- Ectopic prolactin-secreting tumors (hypernephroma, bronchogenic carcinoma)
- Infiltrating diseases of the pituitary (sarcoidosis, histiocytosis)
- Head trauma, chest wall injury, spinal cord injury
- Polycystic ovary disease, pregnancy, nipple stimulation
- Idiopathic hyperprolactinemia, stress, exercise

WORKUP

- The diagnosis of prolactinoma is established by demonstration of an elevated serum prolactin level (after exclusion of other causes of hyperprolactinemia) and radiographic evidence of a pituitary adenoma.
  1. Normal mean prolactin levels are 8 ng/ml in women and 5 ng/ml in men.
  2. Prolactin levels >100 ng/ml are suspicious for prolactinomas. Most macroprolactinomas raise prolactin levels >250 ng/ml and levels >500 ng/ml are virtually diagnostic of macroprolactinomas.
  3. Prolactin levels can vary with time of day, stress, sleep cycle, and meals. More accurate measurements can be obtained 2 to 3 hr after awakening, preprandially, and when patient is not distressed.
  4. Serial measurements are recommended in patients with mild prolactin elevations.
- TSH, free T_4, BUN, Creat, ALT, AST are useful tests. Pregnancy test in all women of childbearing age.
- All patients with prolactinomas should undergo visual field testing. Serial evaluation is recommended, particularly during pregnancy in patients with macroadenomas.

IMAGING STUDIES

- MRI with gadolinium enhancement is the procedure of choice in the radiographic evaluation of pituitary disease.
- In absence of MRI, a radiographic diagnosis is best accomplished with a high-resolution CT scanner and special coronal cuts through the pituitary region.

TREATMENT

NONPHARMACOLOGIC THERAPY

Pregnancy and breastfeeding should be avoided because they can encourage tumor growth.

ACUTE GENERAL Rx

- Management of prolactinomas depends on their size and encroachment on the optic chiasm and other vital structures, the presence or absence of gonadal dysfunction, and the patient's desires regarding fertility. Patients with microprolactinomas without symptoms of hypogonadism do not require treatment. Fig. 2 describes a management algorithm for prolactinomas. Women with hypogonadism related to a microadenoma who do not desire fertility can be treated with a combined oral contraceptive.
- Medical therapy is preferred when fertility is an important consideration. Prolactinomas are treated with the dopamine agonists (DA) bromocriptine and cabergoline.
  1. Bromocriptine: Initial dose is 0.625 mg at bedtime for the first wk. After 1 wk, add morning dose of 1.25 mg. Gradually increase dose by 1.25 mg/wk until dose of 5 to 10 mg/day is achieved. Bromocriptine decreases size of the tumor and generally lowers the prolactin level into the normal range when the initial serum prolactin is <500 ng/ml. Side effects of bromocriptine are nausea, constipation, dizziness, and nasal stuffiness. Bromocriptine appears to be safe during pregnancy.
  2. Cabergoline is a longer-acting dopamine agonist that is more expensive but may be more effective and better tolerated than bromocriptine; initial dose is 0.25 mg twice weekly.
  3. After therapy is initiated, MRI should be repeated in 1 yr for microprolactinomas if the prolactin level normalizes. For macroprolactinomas, MRI is repeated after 2 mo and every 6 to 12 mo until stable on serial studies.
- Transsphenoidal resection: Option in an infertile patient who cannot tolerate bromocriptine or cabergoline or when medical therapy is ineffective. The success rate depends on the location of the tumor (entirely intrasellar), experience of the neurosurgeon, and size of the tumor (<10 mm in diameter); the recurrence rate may reach 80% within 5 yr. Possible complications of transsphenoidal surgery vary with experience and skill of the neurosurgeon and tumor anatomy and include transient diabetes insipidus, hypopituitarism, cerebrospinal fluid rhinorrhea, and infections (meningitis, wound infection).
- Pituitary irradiation is useful as adjunctive therapy of macroadenomas (>10 mm in diameter) and in patients with persistent hypersecretion after surgery. Potential complications include cranial nerve damage, radionecrosis, and cognitive abnormalities.
- Stereotactic radiosurgery (gamma knife) has become popular as a modality in the treatment of prolactinomas. A high dose of ionizing radiation is delivered to the tumor through multiple ports. Its advantage is minimal irradiation to surrounding tissues. Proximity of the tumor to the optic chiasm limits this therapeutic modality.

CHRONIC Rx

- Patients on medical therapy require periodic measurement of prolactin levels. An attempt to reduce the dose of bromocriptine or cabergoline can be made after the prolactin level has been normal for 2 yr. An MRI scan of the pituitary should be obtained to rule out tumor enlargement within 6 mo of initiation of tapering regimen.
- Evaluation and monitoring of pituitary function are recommended after transsphenoidal surgery.

DISPOSITION

- Transsphenoidal surgery will result in a cure in nearly 50% to 75% of patients with microadenomas and 10% to 20% of patients with macroadenomas.
- Nearly 20% of microprolactinomas resolve during long-term dopamine agonist treatment.

PEARLS & CONSIDERATIONS

COMMENTS

- Patients must be monitored for several yrs after surgery because up to 50% of

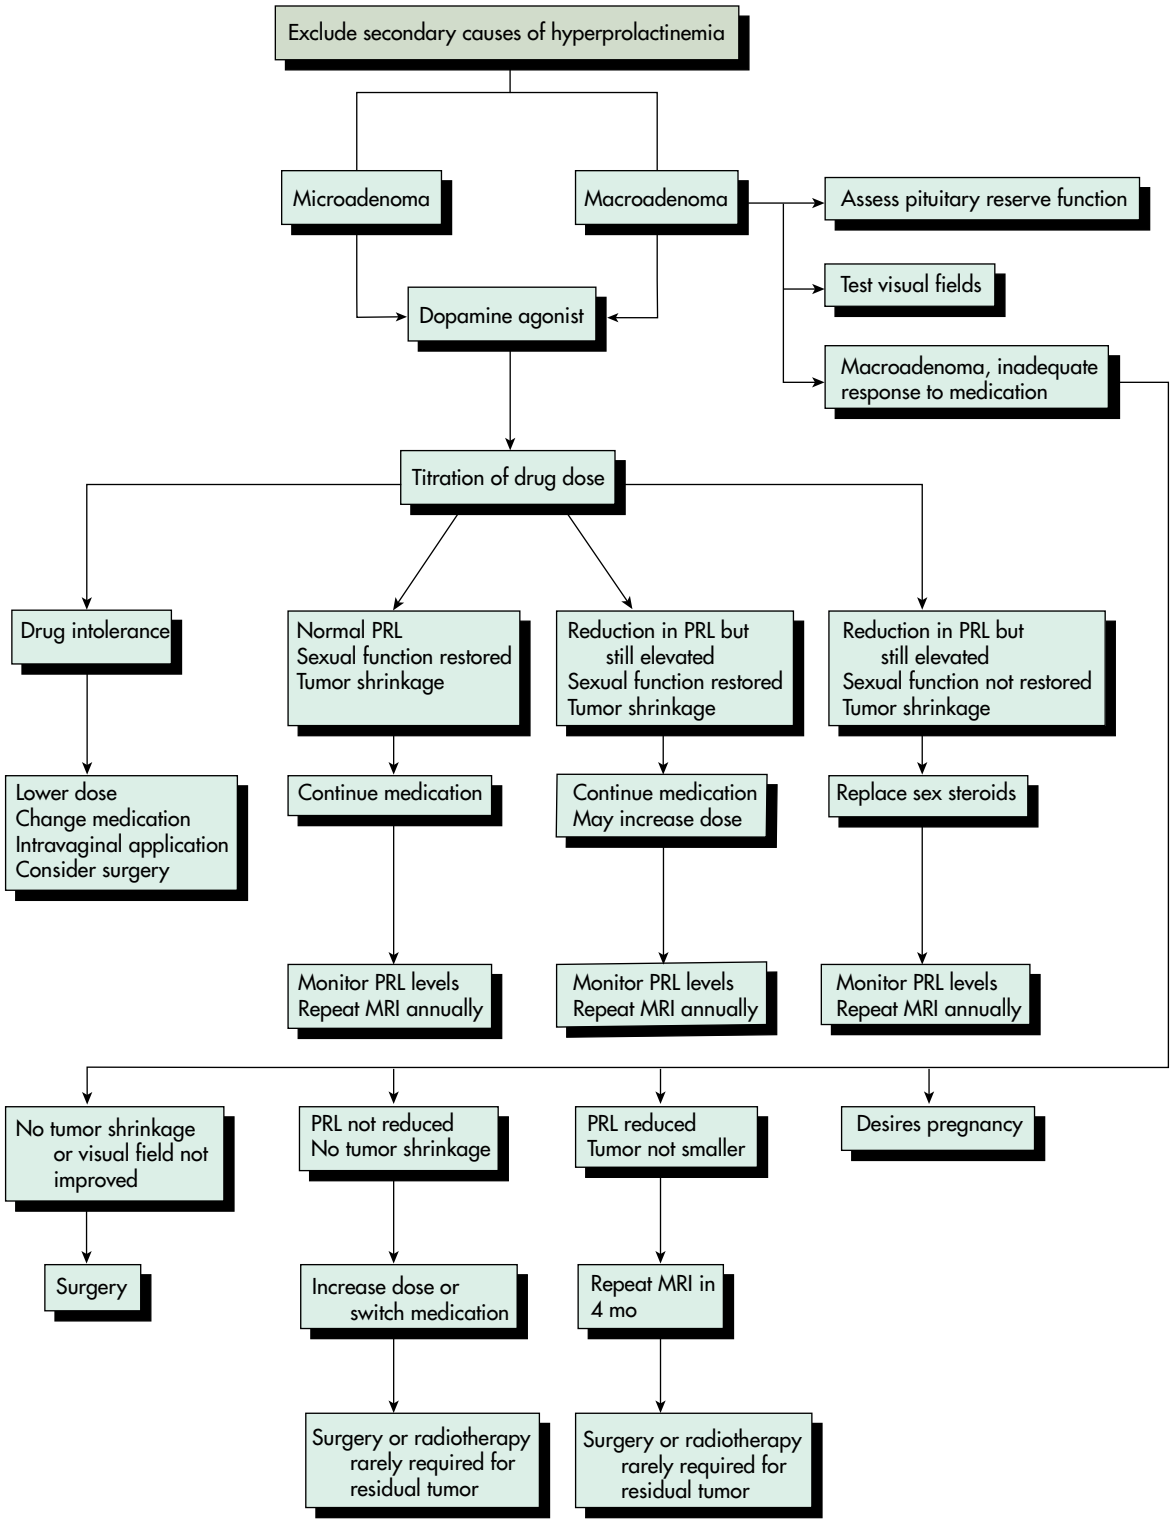

FIG. 2 Prolactinoma management. After secondary causes of hyperprolactinemia have been excluded, subsequent management decisions are based on clinical imaging and biochemical criteria. *MRI,* Magnetic resonance imaging; *PRL,* prolactin. (Modified from Larsen PR et al: *Williams textbook of endocrinology,* ed 11, Philadelphia, 2008, Saunders.)

microadenomas and nearly 90% of macroadenomas can recur.

- Pituitary microadenomas are found in 10.9% of autopsies, and 44% of these microadenomas are prolactinomas.

Pronator Syndrome

BASIC INFORMATION

DEFINITION

Pronator syndrome is a form of compression neuropathy of the median nerve in the proximal forearm caused primarily by the pronator teres muscle; however, other areas of entrapment can also be encountered (Fig. E1). Occasionally, only the anterior interosseous motor branch is affected, causing a specific motor palsy of the median nerve.

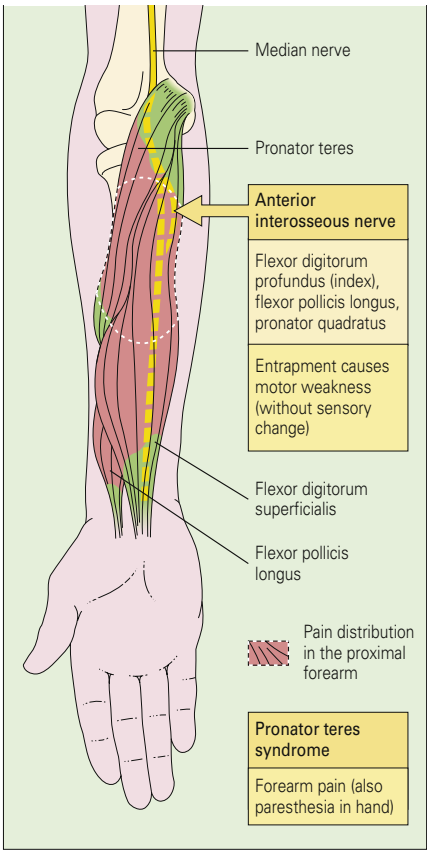

FIG. E1 Forearm entrapment regions. The median nerve may be compressed at several locations in the forearm, most commonly as it traverses the pronator teres muscle. The anterior interosseus branch of the median nerve is solely for motor, and thus entrapment produces no sensory deficit. (From Hochberg MC et al [eds]: Rheumatology, ed 3, St Louis, 2003, Mosby.)

SYNONYM

Kiloh-Nevin syndrome (anterior interosseous syndrome)

ICD-10CM CODES

G56.10	Other lesions of median nerve, unspecified upper limb
G56.90	Unspecified mononeuropathy of unspecified upper limb

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Rare (comprises <1% of median nerve entrapment disorders); most common in dominant arm.

PREDOMINANT SEX: Males are affected more often than females.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Forearm discomfort and fatigue, often resulting from repetitive pronation.
- Insidious onset.
- Nocturnal paresthesias are not typical.
- Vague numbness in hand, primarily in thumb and index finger, may be present, similar to carpal tunnel syndrome.
- Distinguished from carpal tunnel syndrome by paresthesias and/or numbness in the palmar cutaneous branch of the median nerve.
  - Palmar cutaneous branch supplies the radial palm including the thenar eminence.
- Tenderness and enlargement of the pronator teres may be present.
- Tinel sign may be positive at the site of compression in the proximal forearm.
- Although there are no reliable provocative tests, painful paresthesias may occasionally be elicited with forced pronation of the forearm against resistance.
- Motor impairment is rare.

Anterior interosseous nerve (AIN) syndrome:

- Forearm pain and weakness.
- Patient may be unable to form a circle when trying to pinch the index finger and thumb because of the inability to flex distal phalanges of thumb and index finger using the flexor pollicis longus and flexor digitorum profundus to the index finger, respectively.
- Sensation to the hand is not affected.

ETIOLOGY

- Localized anatomic compression
- Trauma
- Traumatic cutdown or phlebotomy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Carpal tunnel syndrome
- Cervical disk syndrome with radiculopathy
- AIN syndrome
- Brachial plexopathy
- Tendon rupture
- Tendinitis

WORKUP

- Electrodiagnostic studies may be helpful but are not required; they are indicated if symptoms persist >4 to 6 wk or if motor weakness is suspected. Often these tests are normal or inconclusive.
- Plain radiography to rule out bony abnormalities causing compression.

TREATMENT

- Rest, activity modification, bracing of forearm, sling
- Flexor muscle stretching exercises, physical therapy
- Nonsteroidal antiinflammatory medications
- Corticosteroid injection

DISPOSITION

Patients whose symptoms are mainly subjective often respond to nonsurgical management. Motor deficits may not be reversible despite surgery. Six mo to a yr of nonoperative therapy is recommended.

REFERRAL

Surgical referral in cases of failed medical management or when motor weakness is present.

PEARLS & CONSIDERATIONS

COMMENTS

Prognosis for recovery is good. When indicated, surgical intervention is most effective if the compression can be confirmed by objective testing.

BASIC INFORMATION

DEFINITION & CLASSIFICATION

Prostate cancer is a neoplasm involving the prostate. Various classifications have been developed to evaluate malignancy potential and prognosis.

- The degree of malignancy varies with the stage:
  1. Stage A: Confined to the prostate, no nodule palpable.
  2. Stage B: Palpable nodule confined to the gland.
  3. Stage C: Local extension.
  4. Stage D: Regional lymph nodes or distant metastases.
- In the Gleason classification (Box E1 and Fig. E1), two histologic patterns are independently assigned numbers 1 to 5 (best to least differentiated). These numbers are added to give a total tumor score between 2 and 10. Prognosis is best for highly differentiated tumors (e.g., Gleason score 2-4) compared with most poorly differentiated tumors (Gleason score 7-10).
- Another commonly used classification is the Tumor-Node-Metastasis (TNM) classification of prostate cancer (Table 1).
- Table 2 summarizes the definition of risk groups and biopsy criteria.

ICD-10CM CODES

C61 Malignant neoplasm of prostate
D07.5 Carcinoma in situ of prostate

EPIDEMIOLOGY & DEMOGRAPHICS

- Prostate cancer has surpassed lung cancer as the most common nonskin cancer in men.
- In the United States, more than 220,000 new cases are diagnosed yearly, and nearly 30,000 males die from prostate cancer each year (second leading cause of death from cancer in U.S. men).
- Incidence of prostate cancer increases with age: Uncommon <50 yr; 80% of new cases are diagnosed in patients aged ≥65 yr. Widespread prostate-specific antigen (PSA) testing has doubled the incidence of prostate cancer and the lifetime risk for prostate cancer to approximately 16%. Prostate cancer is also diagnosed earlier, and the incidence of clinically "silent" T_1 tumors has increased from 17% in 1989 to 48% in 2001 since the advent of PSA screening. Currently, approximately 80% of prostate cancer cases are diagnosed as localized disease and only 4% as metastatic disease.
- Prostate cancer is found at autopsy in more than half of U.S. men older than 50 yr but is the cause of death in only 3%.
- Average age at time of diagnosis is 72 yr.
- Blacks in the United States have the highest incidence of prostate cancer in the world (one in every nine males).
- Incidence is low in Asians.
- Approximately 9% of all prostate cancers may be familial. Obesity is a risk factor for prostate cancer. High-fat, low-fiber diet increases risk. High insulin levels may also increase the risk of prostate cancer. Dietary supplementation with vitamin E has been reported to significantly increase the risk of prostate cancer among healthy men. Linkage studies have implicated chromosome 17p21-22 as a possible location of a prostate-cancer susceptibility gene. Germline mutations in *HOXB13* are associated with a significantly increased risk of hereditary prostate cancer.
- Mortality rates of prostate cancer have declined substantially in the past 15 yr from 34% in 1990 to <20% currently.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Generally silent disease until it reaches advanced stages.
- Bone pain and pathologic fractures may be initial symptoms of prostate cancer.
- Local growth can cause symptoms of outflow obstruction.
- Digital rectal examination (DRE) may reveal an area of increased firmness; 10% of patients will have a negative DRE.
- Prostate may be hard, fixed, with extension of tumor to the seminal vesicles in advanced stages.

TABLE 1 Prostate Cancer

T Stage		
T_x	Primary tumor is not assessable	
T_0	There is no evidence of primary tumor	
T_1	Tumor is not clinically palpable or detected with imaging	
	T_{1a}	*An incidental histological finding in ≤5% of resected tissue (e.g., TURP)*
	T_{1b}	*An incidental histological finding in >5% of resected tissue (e.g., TURP)*
	T_{1c}	*Tumor is identified by needle biopsy*
T_2	Prostate-confined tumor that is clinically palpable or detected with imaging	
	T_{2a}	*Tumor involves ≤1/2 of one prostate lobe*
	T_{2b}	*Tumor involves >1/2 of one prostate lobe (but not both lobes)*
	T_{2c}	*Tumor involves both lobes*
T_3	There is tumor extension through the prostate capsule	
	T_{3a}	*Unilateral or bilateral tumor extension through the prostate capsule*
	T_{3b}	*Seminal vesical involvement*
T_4	Tumor invades structures other than the seminal vesicles (e.g., the bladder neck, rectum, or pelvic wall)	
N Stage		
N_x	The lymph nodes are not assessable	
N_0	There is no tumor spread	
N_1	There is tumor spread to one or more regional pelvic nodes	
M Stage		
M_0	There is no tumor spread beyond the regional pelvic nodes	
M_1	There is tumor spread beyond the regional pelvic nodes	
	M_{1a}	*Tumor spread to nodes outside of the pelvis*
	M_{1b}	*Tumor spread to bones*
	M_{1c}	*Tumor spread to other organs (e.g., lung, liver and brain) ± bone involvement*

From Grant, LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Benign prostatic hypertrophy
- Prostatitis
- Prostate stones

LABORATORY TESTS

- Measurement of PSA is controversial in early diagnosis of prostate cancer. PSA screening is associated with psychological harm, and its potential benefits remain uncertain. In asymptomatic men with no history of prostate cancer, screening using PSA does not reduce all-cause mortality or death from prostate cancer. Normal PSA is found in >20% of patients with prostate cancer, whereas only 20% of men with PSA levels between 4 ng/ml and 10 ng/ml have prostate cancer. Most guidelines encourage a shared decision-making approach between patient and physician regarding PSA testing. Available evidence favors clinician discussion of the pros and cons of PSA screening with average-risk men aged 65 to 69 yr. Only men who express a definite preference for screening should have PSA testing. Rather than widespread annual PSA screening, a reasonable approach may be to focus on high-risk men (those with PSA levels ≥2 ng/ml at age 60). The American Cancer Society recommends offering the PSA test and DRE yearly to men aged ≥50 yr who have a life expectancy of at least 10 yr. Earlier testing, starting at age 40 to 45 yr, is recommended for men at high risk (e.g., blacks, men with family history of prostate cancer). An isolated elevation in PSA level should be confirmed several weeks later before proceeding with further

TABLE 2 Definition of Risk Groups

Risk Group	Clinical Stage	PSA (ng/ml)	Gleason Score	Biopsy Criteria
Low	T_{1a} or T_{1c}	<10	2-6	Unilateral or <50% of core involved
Intermediate	T_{1b}, T_{1c}, or T_{2a}	<10	3 + 4 = 7	Bilateral
High	T_{1b}, T_{1c}, T_{2b}, or T_3	10-20	4 + 3 = 7	>50% of core involved or perineural invasion or ductal differentiation
Very high	T_4	>20	8-10	Lymphovascular invasion or neuroendocrine differentiation

From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

testing, including prostate biopsy. Screening for prostate cancer in men aged ≥75 yr is controversial and generally not recommended. The American College of Physicians (ACP) recommends that clinicians should not screen for prostate cancer using the PSA in average-risk men under age 50, men over age 69, or men with a life expectancy of <10 to 15 yr. The U.S. Preventive Services Task Force (USPSTF) recommends against PSA-based screening for prostate cancer in all age groups. According to the USPSTF:

1. The magnitude of harms from screening (e.g., falsely high PSA levels, psychological effects, unnecessary biopsies, overdiagnosis of indolent tumors) is "at least small."
2. The magnitude of treatment-associated harms (i.e., adverse effects of surgery, radiation, and hormonal therapy) is "at least moderate."
3. The 10-yr mortality benefit of PSA-based prostate cancer screening is "small to none."
4. The overall balance of benefits and harms results in "moderate certainty that PSA-based screening has no net benefit."

- Free PSA: The use of serum free PSA for prostate screening has been proposed by some urologists as a means to decrease unwarranted biopsies without missing a significant number of prostate cancers. This approach is based on the higher free PSA in men with benign prostatic hyperplasia and the higher protein-bound PSA levels in men with prostate cancer. For example, in men with total PSA levels of 4 to 10 ng/ml, the cancer probability is 0.25, but if the percentage of free PSA is ≤17%, the probability of cancer increases to 0.45.
- PSA velocity: The rate of increase of serum PSA over time (PSA velocity) can aid in the diagnosis of prostate cancer. A yearly PSA velocity >0.75 ng/ml increases the likelihood of later malignancy when total PSA is still within normal range. Proper interpretation of PSA velocity requires at least three PSA measurements over an 18-mo period because most PSA variations are physiologic. Recent trials have cast a doubt on the value of PSA velocity by showing that adding PSA velocity as a trigger for biopsy did not improve predictive accuracy beyond that of using PSA threshold values alone.
- Age-adjusted PSA: There is evidence that the current threshold of 4.0 ng/ml is inadequate for younger men, because in a recent study 22% of men with PSA levels between 2.6 and 4.0 were found to have prostate cancer. The concept of age-related cutoffs remains controversial. Lowering the upper limit of normal for PSA would improve sensitivity but decrease specificity.
- Prostatic acid phosphatase can be used for evaluation of nonlocalized disease.
- Prostate cancer gene 3 *(PCA3)* is overexpressed in prostate cancer cell, and high levels are suggestive of prostate cancer. Measurement of *PCA3* in urine specimens collected after digital exams is helpful to make decisions about prostate biopsy in men with elevated PSA.
- Transrectal biopsy and fine-needle aspiration of prostate can confirm the diagnosis. Indications for biopsy include an abnormal PSA level, an abnormal DRE, or a previous biopsy specimen that showed prostatic intraepithelial neoplasia or prostatic atypia. The number of cores taken is patient specific, typically including a minimum of 10 cores. Prostate volume negatively affects cancer detection rate (23% in glands >50 cm^3, 38% in glands <50 cm^3).

IMAGING STUDIES (FIGS. E2 THROUGH E5)

- Bone scan is useful to evaluate bone metastasis (present or eventually develops in almost 80% of patients). However, according to the American Urological Association (AUA), the routine use of bone scanning is not required for staging of prostate cancer in asymptomatic men with clinically localized cancer if the PSA level is ≤20 ng/ml.
- CT scan, MRI, and transrectal ultrasonography may be useful in selected patients to assess extent of prostate cancer. High-resolution MRI with magnetic nanoparticles has been used for the detection of small and otherwise undetectable lymph node metastases in patients with prostate cancer. However, according to the AUA, transrectal ultrasonography adds little to the combination of PSA and DRE. Similarly, CT and MRI imaging are generally not indicated for cancer staging in men with clinically localized cancer and PSA <25 ng/ml. With regard to pelvic lymph node dissection in staging, the AUA states that it may not be required in patients with PSA levels <10 ng/ml and when PSA level is <20 ng/ml and the Gleason score is <6.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Watchful waiting is reasonable in selected patients with early-stage (T_{1a}) and projected life expectancy <10 yr or in patients with focal and moderately differentiated carcinoma.

ACUTE GENERAL Rx

- Therapeutic approach varies with the following:
  1. Stage of the tumor
  2. Patient's life expectancy
  3. General medical condition
  4. Patient's treatment preference (e.g., patient may be opposed to orchiectomy)
- The optimal treatment of clinically localized prostate cancer is unclear. It is important to remember that all forms of treatment have potential adverse effects. Management requires careful consideration of the potential benefits and harms of intervention, the patient's age, health status, and individual preferences. A treatment algorithm for prostate cancer is described in Fig. 6. Table 3 summarizes recommended treatment based on risk group and life expectancy.
  1. Radical prostatectomy is generally performed in patients with localized prostate cancer and life expectancy >10 yr. Radical prostatectomy reduces disease-specific mortality, overall mortality, and the risks of metastasis and local progression. The absolute reduction in the risk of death after 10 yr is small, but the reductions in the risks of metastasis and local tumor progression are substantial. A 29 yr follow-up comparing radical prostatectomy with watchful waiting showed that men with clinically detected, localized prostate cancer and a long life expectancy benefited from radical prostatectomy with a mean 2.9 yr of life gained. Postoperative complications of radical prostatectomy include urinary incontinence (10% to 20% depending on degree of neurovascular bundle and urethral preservation, patient age, and correct mucosal apposition) and erectile dysfunction (percentage >50% and varies with patient age, preoperative erectile dysfunction, stage of tumor at time of surgery, and preservation of neurovascular bundle). Lower complication rates occur in hospitals that perform a large number of prostatectomies. Fewer men will have postsurgical erectile dysfunction after unilateral or bilateral nerve-sparing surgery. In men undergoing prostatectomy, robotic-assisted laparoscopic surgery represents an alternative to open retropubic radical prostatectomy. Despite advertisements that suggest that there

TABLE 3 Recommended Treatment

Risk Group	Life Expectancy (Yr)	Recommended Treatment
Low	0-5	AS, HT
	5-10	AS, RT, HT, 0
	>10	RP, RT, AS, 0
Intermediate*	0-5	AS, HT, RT, 0
	5-10	RT, HT, RP, 0
	>10	RP, RT, 0, HT
High*	0-5	AS, RT + HT, 0
	5-10	RT + HT, HT, RP, 0
	>10	RT + HT, RP + RT + HT, HT
Very high*	0-5	AS, RT + HT, 0
	5-10	H, RT + HT, ST
	>10	RT + HT, RP + RT + HT, HT, ST, IT

AS, Active surveillance; *HT,* hormone therapy; *IT,* investigational multimodal therapy; *0,* others; *RP,* radical prostatectomy; *RT,* radiation therapy; *ST,* systemic therapy.
*If there is more than a 20% probability of positive lymph nodes, AS, HT, ST + HT.
From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

are fewer complications after robotic surgery, data show that sexual dysfunction occurs postoperatively in about 88% of patients who have undergone robotic-assisted or conventional prostatectomy and that incontinence problems are more prevalent (33%) with robotic surgery than with open retropubic radical prostatectomy (RPP) (27%). Trials have shown that prostatectomy is preferred over "watchful waiting" in patients with localized prostate cancer detected by PSA if the PSA level is >10 ng/ml. In this subgroup, the 10-yr mortality is 48.4% with prostatectomy versus 61.6% with watchful waiting. In men who have low-risk disease (PSA level <10 mcg/L, stage $<T_{2a}$, Gleason score ≤3 + 3), and <6% risk for prostate cancer–specific death at 15 yr, watchful waiting (WW) and active surveillance (AS) are reasonable and underutilized options.

TABLE 4 Major Circulating Androgens

Source	Androgen	Amount Produced/Day (mg)	Relative Potency	Relative Potency/Amount Produced
Testes	Testosterone	6.6	100	15.2
Testes and peripheral tissues	Dihydrotestosterone	0.3	160-190	533-633
Adrenal glands	Androstenedione	1.4	39	27.9
Adrenal glands	Dehydroepiandrosterone	29	15	0.5

From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

2. Radiation therapy (external-beam irradiation or brachytherapy with implantation of radioactive pellets [iodine-125 or palladium-103 seeds] into the prostate gland) represents an alternative in patients with localized prostate cancer, especially poor surgical candidates or patients with a high-grade malignancy. The efficacy of brachytherapy is comparable to external radiation. In patients receiving external-beam radiation, a total dose of 79.2 Gy (high dose) compared with a total dose of 70.2 Gy (conventional dose) has been reported to lower the risk of recurrence without increased risk of morbidity and mortality. Newer radiation treatments such as intensity-modulated radiation therapy (IMRT) and proton therapy are becoming increasingly popular and replacing the older technique of conformal radiation therapy over the past 10 yr. Trials have shown that among patients with nonmetastatic prostate cancer, the use of IMRT compared with conformal therapy is associated with less gastrointestinal morbidity and fewer hip fractures but more erectile dysfunction; IMRT compared with proton therapy is associated with less GI morbidity. Patients with localized prostate cancer and high risk for extraprostatic disease and disease recurrence (e.g., Gleason score ≤7 with multiple positive biopsy cores and clinical stage T_{1b}-T_{2b}) may benefit (increased overall survival) with the addition of 6 mo of androgen suppression therapy to radiation therapy.
3. Watchful waiting is reasonable in patients who are too old or too ill to survive longer than 10 yr. If the cancer progresses to the point where it becomes symptomatic, palliation can be attempted with several methods. Conservative management is also reasonable for patients with Gleason score of 2 to 4 because these patients do not have a shortened life expectancy and treatment is associated with long-term side effects. Watchful waiting also appears to be safe in older men with less-aggressive disease. Individual preferences play a central role in the decision whether to treat or to pursue active surveillance.

- Patients with advanced disease and projected life expectancy <10 yr are candidates for radiation therapy and hormonal therapy (diethylstilbestrol, luteinizing hormone–releasing hormone analogues, antiandrogens, bilateral orchiectomy).
- Recommended treatment of patients with regional metastatic prostate cancer with projected life expectancy ≥10 yr includes radiation therapy and hormonal therapy.
- Prostate cancer is an androgen-receptor-dependent disease, and the blocking of androgen-receptor signaling is an effective treatment modality. Table 4 summarizes major circulating androgens. Androgen deprivation therapy (ADT) is the mainstay of treatment for metastatic prostate cancer. Adverse effects of ADT include decreased libido, impotence, hot flashes, osteopenia with increased fracture risk, metabolic alterations, and changes in mood and cognition. Adjuvant treatment with luteinizing hormone-releasing hormone (LHRH) agonists (goserelin, leuprolide, or triptorelin) plus antiandrogens (flutamide, bicalutamide, or nilutamide), when started simultaneously with external-beam radiation, improves local control and survival in patients with locally advanced prostate cancer. Pamidronate inhibits osteoclast-mediated bone resorption and prevents bone loss in the hip and lumbar spine in men receiving treatment for prostate cancer. Gonadotropin-releasing hormone (GnRH) receptor antagonists can be used for rapid medical castration of men with advanced prostate cancer. Degarelix is an injectable GnRH agonist useful to suppress testosterone in patients with prostate cancer who are not good candidates for LHRH agonists and refuse surgical castration. Assessment of bone density and treatment with once-weekly oral alendronate can prevent and improve the bone loss that occurs in men receiving ADT for prostate cancer.
- Docetaxel plus prednisone or docetaxel plus estramustine can be used in metastatic hormone–refractory prostate cancer. Newer treatments for hormone–refractory prostate cancer (castration-resistant cancer) include immunotherapy with sipuleucel and cabazitaxel, a microtubule inhibitor that interferes with cell mitosis and replication. Both agents can prolong survival but adverse effects can be severe and both agents are very expensive. Abiraterone is an oral agent that blocks biosynthesis of androgens by inhibiting CYP17, an enzyme required for androgen biosynthesis. It has been FDA approved for oral treatment, in combination with prednisone, of metastatic castration-resistant prostate cancer in patients previously treated with docetaxel.
- Enzalutamide is a newer nonsteroidal antiandrogen. Trials have shown it to be highly effective in extending survival in patients with metastatic castration-resistant prostate cancer. It can be used sequentially with other agents such as docetaxel, abiraterone, cabazitaxel, and immunotherapy. Radium-223, an alpha emitter, selectively targets bone metastases and has been found effective in improving survival in men with castration-resistant prostate cancer and bone metastases.
- The polyadenosine diphosphate [ADP]-ribose) polymerase (PARP) inhibitor has shown a high response rate in patients whose prostate cancers were no longer responding to standard treatments and who had defects in DNA-repair genes.

CHRONIC Rx

- Patients should be monitored at 3- to 6-mo intervals with clinical examination and PSA for the first yr, then every 6 mo for the second yr, then yearly if stable. For patients who have undergone radical prostatectomy, a rising PSA level suggests evidence of residual or recurrent prostate cancer. A recent study revealed that if the PSA level remains undetectable 3 to 5 yr after radical prostatectomy, the probability of biochemical recurrence is extremely low, and it is reasonable to stop PSA monitoring. [1]Salvage radiotherapy may potentially cure patients with disease recurrence after radical prostatectomy. Recent trials have shown that addition of 24 mo of antiandrogen therapy with daily bicalutamide to salvage radiation therapy results in significantly higher rates of long-term overall survival and lower incidences of metastatic prostate cancer and death from prostate cancer than radiation therapy plus placebo.[2]
- Chest radiography and bone scan should be performed yearly or sooner if patient develops symptoms.

TABLE 5 Common Pain Syndromes in Metastatic Castration-Resistant Prostate Cancer

Pain Syndrome	Initial Management	Other Therapeutic Alternatives
Localized bone pain	Pharmacologic pain management	Surgical stabilization of pathologic fractures or extensive bone erosions
	Localized radiotherapy (special attention to weight-bearing areas, lytic metastasis, and extremities)	Epidural metastasis and cord compression should be evaluated in all patients with focal back pain
		Radiopharmaceuticals should be considered if local radiation therapy fails
Diffuse bone pain	Pharmacologic pain management	Corticosteroids
	"Multispot" or wide-field radiotherapy	Bisphosphonates or RANK ligand inhibitors
	Radiopharmaceuticals	Calcitonin
		Chemotherapy
Epidural metastasis and cord compression	High-dose corticosteroids	Pharmacologic pain management
	Radiation therapy	Physical therapy for recovery of neurologic function
	Surgical decompression and stabilization are indicated in high-grade epidural compressions, extensive bone involvement, or recurrence after irradiation.	
Nerve plexopathies caused by direct tumor extension or previous therapy (rare)	Pharmacologic pain management	Tricyclic antidepressants (amitriptyline)
	Radiation therapy (if not previously used)	Anticonvulsants (gabapentin, pregabalin)
	Neurolytic procedures (nerve blocks)	
Miscellaneous neurogenic causes: Postherpetic neuralgia, peripheral neuropathies	Complete neurologic evaluation	Tricyclic antidepressants (amitriptyline)
	Pharmacologic pain management	Anticonvulsants (gabapentin, pregabalin)
	Discontinuation of neurotoxic drugs: Docetaxel, platinum compounds	
Other uncommon pain syndromes: Extensive skull metastasis with cranial nerve/skull base involvement, extensive painful liver metastasis, or pelvic masses	Radiation therapy	Chemotherapy
	Pharmacologic pain management	Intrathecal chemotherapy may ameliorate symptoms of meningeal involvement
	Corticosteroids (cranial nerve involvement)	

RANK, Receptor activator of nuclear factor-κB.

DISPOSITION

- Prognosis varies with the stage of the disease and the Gleason classification (see "Definition"). For patients between ages 65 and 69 yr at diagnosis and a Gleason score of 2 to 4, the probability of dying from prostate cancer 15 yr after diagnosis is 0.06 and that of dying from other causes is 0.56. If the Gleason score is 7 to 10, the probability of dying from prostate cancer increases to 0.72 and from other causes varies from 0.25 to 0.36.
- The ploidy of the tumor also has prognostic value; prognosis is better with diploid tumor cells and worse with aneuploid tumor cells.
- For grade 1 tumors, the extended 10-yr, disease-specific survival is similar for patients with prostatectomy (94%), radiotherapy (90%), and conservative management (93%); survival rate is better with surgery than with radiotherapy or conservative management in patients with grade 2 or 3 localized prostate cancer.
- Expression of the gene *EZH2* has been identified as an important factor in the determination of the aggressiveness of prostate cancer. A recent study revealed that expression of the *EZH2* gene may be a better predictor of clinical failure than Gleason score, tumor stage, or surgical margin status. Testing for EZH2 protein in prostate cancer tissue may be useful to determine prognosis and direct treatment.
- Preoperative PSA level and PSA velocity have prognostic significance. Men whose PSA level increases by >2.0 mcg/ml during the year before the diagnosis of cancer may have a relatively high risk of death from prostate cancer despite undergoing radical prostatectomy.
- Extraprostatic disease is detected at radical prostatectomy in 38% to 52% of patients and is associated with a risk of disease recurrence, progression, and death. In these patients, adjuvant radiotherapy results in significantly reduced risk of PSA relapse and disease recurrence; however, the improvements in metastases-free survival and overall survival are not statistically significant. Table 5 summarizes common pain syndromes in metastatic castration-resistant prostate cancer.
- The Prostate Cancer Prevention trial revealed that the use of 5-alpha-reductase inhibitors lowers the incidence of prostate cancer but also increases the incidence of high-grade tumors (Gleason score >7). It is possible that these agents delay diagnosis of prostate cancer by lowering PSA levels and decreasing prostate size. The trade-off inherent in using 5-alpha-reductase inhibitors for prostate cancer prevention is risk of one additional high-grade cancer in order to avert three or four lower-grade cancers. Based on these results, the FDA's Oncologic Drugs Advisory Committee concluded that finasteride and dutasteride do not have a favorable risk-benefit profile for chemoprevention of prostate cancer in healthy men.
- Patients undergoing prostatectomy are more likely to have urinary incontinence than those undergoing radiotherapy at 2 yr and 5 yr. However, at 15 yr there are no significant relative differences in disease-specific functional outcomes among men undergoing prostatectomy or radiotherapy.
- Bone health is a significant concern in men with prostate cancer. Trials involving bisphosphonates and denosumab reveal that both improve bone mineral density (BMD) in men with nonmetastatic prostate cancer receiving androgen deprivation therapy. Denosumab has also been shown to reduce the risk of vertebral fractures.

BOX E1 2005 International Society of Urological Pathology Modified Gleason System

Pattern 1
Circumscribed nodule of closely packed but separate, uniform, rounded to oval, medium-sized acini (larger glands than pattern 3)

Pattern 2
Like pattern 1, fairly circumscribed, yet at the edge of the tumor nodule there may be minimal infiltration
Glands are more loosely arranged and not quite as uniform as Gleason pattern 1

Pattern 3
Discrete glandular units
Typically smaller glands than seen in Gleason pattern 1 or 2
Infiltrates in and among nonneoplastic prostate acini
Marked variation in size and shape

Pattern 4
Fused microacinar glands
Ill-defined glands with poorly formed glandular lumens
Large cribriform glands
Cribriform glands
Hypernephromatoid

Pattern 5
Essentially no glandular differentiation, composed of solid sheets, cords, or single cells
Comedocarcinoma with central necrosis surrounded by papillary, cribriform, or solid masses

From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

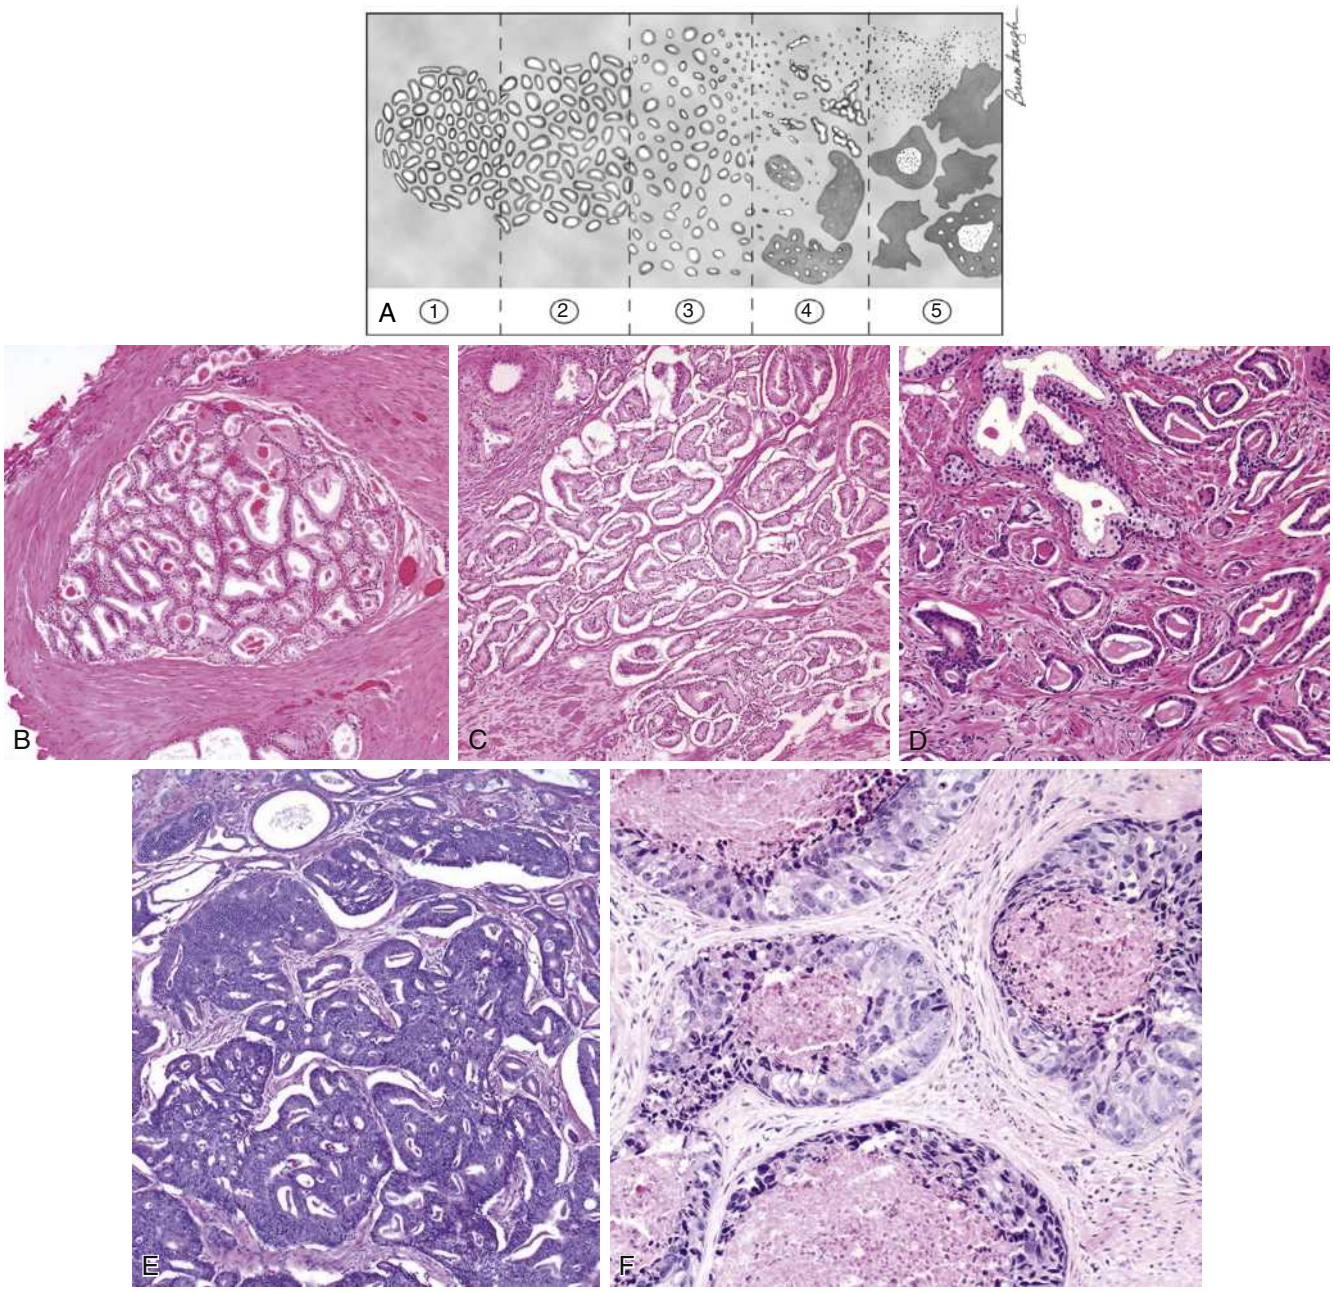

FIG. E1 The Gleason grading system. (A) Schematic diagram of the Gleason grading system. **(B)** Gleason pattern 1: Well-circumscribed nodule of closely packed glands. **(C)** Gleason pattern 2: Nodule with more loosely arranged glands. **(D)** Gleason pattern 3: Small glands with an infiltrative pattern between benign glands. **(E)** Gleason pattern 4: Large irregular cribriform glands. **(F)** Gleason pattern 5: Solid nests of tumor with central comedonecrosis. FIG. E3 Multi-parametric MR images of a 64-yr-old man with a PSA level of 13 ng/ml and 1 negative TRUS biopsy session, showing a typical case of a peripheral zone tumor. With MR-guided biopsy a GS 4 + 4 = 8 was found. **(A)** Axial T2-weighted image. **(B)** Axial ADC map. **(C)** Axial DWI with b = 1400. **(D)** Axial DCE image. (From Adam A, Dixon AK, Gillard JH, Schaefer-Prokop CM: *Grainger and Allison's diagnostic radiology,* ed 6, 2015, Elsevier. In Grant, LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, 2019, Elsevier.)

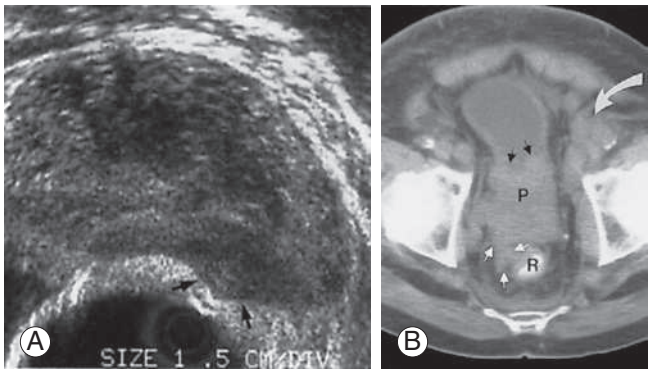

FIG. E4 (A) Stage T_3 prostate carcinoma. TRUS demonstrating an ill-defined hypoechoic area (arrows) within the peripheral zone. The tumor is causing a localized bulge of the prostatic outline beyond the expected contour of the gland. This is the most reliable finding in diagnosing transcapular invasion. **(B)** CT demonstration of prostatic carcinoma with regional lymph node metastasis. The prostate gland (P) is markedly enlarged, and there is direct tumor extension into the perirectal region (small white arrows), rectum (R), and the bladder base (small black arrows). Pronounced left external iliac adenopathy is present (curved arrow). (From Adam A, Dixon AK, Grainger RG, Allison DJ: *Grainger & Allison's diagnostic radiology,* ed 5, 2017, Churchill Livingstone. In Grant, LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, 2019, Elsevier.)

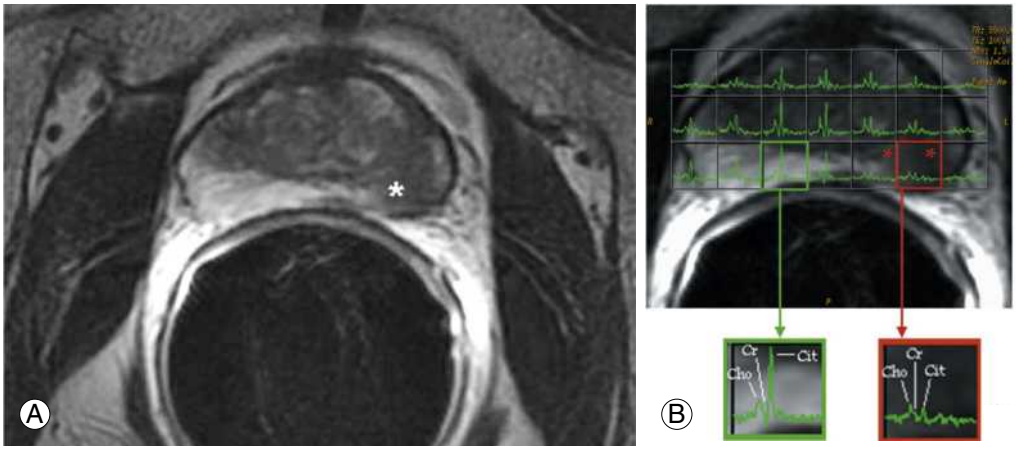

FIG. E5 MRI and 3D 1 H MR spectroscopy of prostate carcinoma. (A) Axial T2WI (endorectal coil), with **(B)** superimposed MR spectroscopic grid and corresponding spectral array to the superimposed grid. The tumor (*) is seen as a low SI in the left peripheral gland. The corresponding MR spectroscopic grid shows concordant results with abnormal metabolism in this area: Green box, healthy tissue ▸ red box, cancer ▸ Cho, choline ▸ Cr, creatine ▸ Cit, citrate. (From Adam A, Dixon AK, Grainger RG, Allison DJ: *Grainger & Allison's diagnostic radiology,* ed 5, 2017, Churchill Livingstone. In Grant, LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, 2019, Elsevier.)

BASIC INFORMATION

DEFINITION

Prostatitis refers to inflammation of the prostate gland. There are four major categories (Table 1):

1. Acute bacterial prostatitis (type I)
2. Chronic bacterial prostatitis (type II)
3. Chronic prostatitis/pelvic pain syndrome (CP/CPPS) (type III): Subdivided into type IIIA (inflammatory) and IIIB (noninflammatory)
4. Asymptomatic inflammatory prostatitis (type IV)

ICD-10CM CODES
N41.0 Acute prostatitis
N41.1 Chronic prostatitis

EPIDEMIOLOGY & DEMOGRAPHICS

- 50% of men will have symptoms of prostatitis in their lifetime.
- Prostatitis accounts for >8% of visits to urologists and 1% of visits to primary care physicians.
- The prevalence of chronic bacterial prostatitis is 5% to 10%.
- CP/CPPS is the most common of the clinically defined prostatitis syndromes, with prevalence ranging from 9% to 12% of men.
- Acute bacterial prostatitis accounts for 10% of all cases of prostatitis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute bacterial prostatitis:
  1. Sudden or rapidly progressive onset of:
     a. Dysuria.
     b. Frequency.
     c. Urgency.
     d. Nocturia.
     e. Perineal pain that may radiate to the back, rectum, or penis.
  2. Hematuria or a purulent urethral discharge may occur.
  3. Occasionally urinary retention complicates the course.
  4. Fever, chills, and signs of sepsis can also be part of the clinical picture.
  5. On rectal examination the prostate is typically tender.
- Chronic bacterial prostatitis:
  1. Characterized by positive culture of expressed prostatic secretions. May cause symptoms such as suprapubic, low back, or perineal pain; mild urgency, frequency, and dysuria with urination; and possibly recurrent urinary tract infections.
  2. May be asymptomatic when the infection is confined to the prostate.
  3. May present as an increase in severity of baseline symptoms of benign prostatic hypertrophy (BPH).
  4. When cystitis is also present, urinary frequency, urgency, and burning may be reported.
  5. Hematuria may be a presenting complaint.
  6. In elderly men, new onset of urinary incontinence may be noted.
- CP/CPPS:
  1. Presents similarly with pain in the pelvic region lasting >3 mo. Symptoms also can include pain in the suprapubic region, low back, penis, testes, or scrotum.
  2. The symptoms can be of variable severity and may include lower urinary tract symptoms, sexual dysfunction, and reduced quality of life.

ETIOLOGY

- Acute bacterial prostatitis:
  1. Acute, usually gram-negative infection of the prostate gland. *E. coli* is the most commonly isolated organism.
     a. Generally associated with cystitis.
     b. Results from the ascent of bacteria into the urethra.
  2. Occasionally the route of infection is hematogenous or a lymphatogenous spread of rectal bacteria.
  3. Consider *Neisseria gonorrhoeae* or *Chlamydia trachomatis* in young patients (age <35 yr) with risk of sexually transmitted disease (STD).
- Chronic bacterial prostatitis:
  1. Often asymptomatic. *E. coli* is the most commonly isolated organism.
  2. Exacerbation of symptoms of BPH caused by the same mechanism as in acute bacterial prostatitis.
- CP/CPPS:
  1. Type IIIA: Refers to symptoms of prostatic inflammation associated with the presence of white blood cells in prostatic secretions with no identifiable bacterial organism.
  2. *Chlamydia* infection may be etiologically implicated in some cases.
  3. Type IIIB: Refers to symptoms of prostatic inflammation with no or few white blood cells in the prostatic secretion. Its cause is multifactorial (Fig. 1).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- BPH with lower urinary tract symptoms
- Prostate cancer
- Interstitial cystitis/bladder pain syndrome
- Pelvic floor dysfunction
- Bladder cancer
- Urolithiasis
- UTI
- Proctitis

WORKUP

- Rectal examination:
  1. Tender prostate most suggestive of acute bacterial prostatitis
  2. Enlarged prostate common in chronic bacterial prostatitis
  3. Normal prostate is consistent with chronic bacterial prostatitis and CP/CPPS
- Expression of prostatic secretions by prostate massage is contraindicated in acute bacterial prostatitis but is appropriate in the other three situations.

LABORATORY TESTS

- Urinalysis
- Urine culture and sensitivity
- Bacterial localization studies can be performed but are cumbersome and impractical in most clinical settings
- Cell count and culture of expressed prostatic secretions
- Prostate-specific antigen (PSA) is not used to diagnose prostatitis and is not recommended unless a nodule is present on digital examination. A rapid rise over baseline should raise the possibility of prostatitis even in the absence of symptoms. In such cases, a follow-up PSA after treatment of prostatitis is appropriate
- Complete blood count and blood cultures if fever, chills, or signs of sepsis exist

TABLE 1 Classification System for the Prostatitis Syndromes

Traditional	National Institutes of Health	Description
Acute bacterial prostatitis	Category I	Acute infection of the prostate gland
Chronic bacterial prostatitis	Category II	Chronic infection of the prostate gland
N/A	Category III Chronic pelvic pain syndrome (CPPS)	Chronic genitourinary pain in the absence of uropathogenic bacteria localized to the prostate gland employing standard methodology
Nonbacterial prostatitis	Category IIIA Inflammatory CPPS	Significant number of white blood cells in expressed prostatic secretions, postprostatic massage urine sediment (VB3), or semen
Prostatodynia	Category IIIB Noninflammatory CPPS	Insignificant number of white blood cells in expressed prostatic secretions, postprostatic massage urine sediment (VB3), or semen
N/A	Category IV Asymptomatic inflammatory prostatitis (AIP)	White blood cells (and/or bacteria) in expressed prostatic secretions, postprostatic massage urine sediment (VB3), semen, or histologic specimens of prostate gland

From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

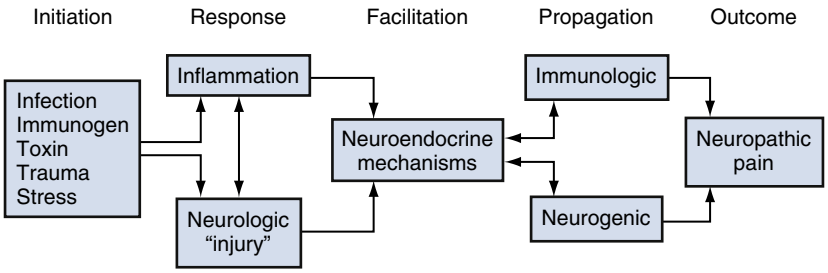

FIG. 1 The cause and pathogenesis of chronic prostatitis/chronic pelvic pain syndrome (category III chronic pelvic pain syndrome) appears to involve a pluricausal, multifactorial mechanism. An initiating stimulus, such as infection, reflux of some toxic or immunogenic urine substance, or perineal or pelvic trauma, starts a cascade of events in an anatomically or genetically susceptible man, resulting in a local response of inflammation or neurogenic injury or both. Further interrelated immunologic, neuropathic, endocrinologic, and psychologic mechanisms propagate or sustain the chronicity of the initial (or ongoing) event. The final outcome is the clinical manifestation of chronic perineal or pelvic pain and associated symptoms with local and central neuropathic mechanisms involving areas outside the prostate or pelvic area. (From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.)

BOX 1 Suggested Therapies for Chronic Prostatitis and Chronic Pelvic Pain Syndrome (National Institutes of Health Category III)

Recommended

1. α-Blocker therapy as part of a multimodal treatment strategy for newly diagnosed, α-blocker–naive patients who have voiding symptoms
2. Antimicrobial therapy trial for selected newly diagnosed, antimicrobial-naive patients
3. Selected phytotherapies: Cernilton and quercetin
4. Multimodal therapy directed by clinical phenotype
5. Directed physiotherapy. Although level 1 evidence is not available, evidence from multiple weak trials and vast clinical experience strongly suggests benefit for selected patients

Not Recommended

1. α-Blocker monotherapy, particularly in patients previously treated with α-blockers
2. Antiinflammatory monotherapy
3. Antimicrobial therapy as primary therapy, particularly for patients in whom treatment with antibiotics has previously failed
4. 5α-Reductase inhibitor monotherapy; can be considered in older patients with coexisting benign prostatic hyperplasia
5. Most minimally invasive therapies such as transurethral needle ablation (TUNA), laser therapies
6. Invasive surgical therapies such as transurethral resection of the prostate (TURP) and radical prostatectomy

Requiring Further Evaluation

1. Low-intensity shock wave treatment
2. Acupuncture
3. Biofeedback
4. Invasive neuromodulation (e.g., pudendal nerve modulation)
5. Electromagnetic stimulation
6. Botulinum toxin A injection
7. Medical therapies including mepartricin, muscle relaxants, neuromodulators, and immunomodulators

Modified from Nickel JC et al: Male chronic pelvic pain syndrome (CPPS). In Chapple C, Abrams P [eds]: *Male lower urinary tract symptoms (LUTS). An international consultation on male LUTS, Fukuoka, Japan, Sept 30–Oct 4, 2012*, Montreal, 2013, Société Internationale d'Urologie. From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

Rx TREATMENT

- Acute bacterial prostatitis:
  1. Uncomplicated (with risk of STD, age <35 yr): Ceftriaxone 250 mg IM × 1 dose *or* cefixime 400 mg PO × 1 *then* doxycycline 100 mg bid × 10 days.
  2. Uncomplicated with low risk of STD: Levofloxacin 500 mg qid or ciprofloxacin 500 mg bid × 10 to 14 days.
- Chronic bacterial prostatitis:
  1. First-line choice is a quinolone (ciprofloxacin or levofloxacin) for 4 wk.
  2. Trimethoprim-sulfamethoxazole (TMP-SMX) is second-line choice for 1 to 3 mo if the organism is sensitive. Tissue penetration for TMP-SMX is not as good as quinolones, and there is evidence of increasing uropathogenic resistance.
- CP/CPPS:
  1. Suggested therapies for CP/CPPS are summarized in Box 1.

BASIC INFORMATION

DEFINITION

Pruritus ani refers to an intense chronic itching of the anus and perianal skin.

SYNONYM

Anal neurodermatitis

ICD-10CM CODE
L29.0 Pruritus ani

EPIDEMIOLOGY & DEMOGRAPHICS

- Any age can be affected
- Occurs in 1% to 5% of the population
- Male:female predominance of 4:1
- Many of these patients may not present to care
- More common in ages 40 to 60s

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Anal itching
- Anal fissures
- Hemorrhoids
- Excoriations
- Pinworms
- Fecal incontinence

ETIOLOGY

Anorectal diseases and fecal contamination:
- Diarrhea
- Anal incontinence
- Prolapsed internal hemorrhoids
- Fissures
- Fistulae
- Rectal prolapse
- Malignancy: Bowen disease, epidermoid cancer, perianal Paget disease

Infections:
- Fungal: Candidiasis, dermatophytes
- Parasitic: Pinworms, scabies
- Bacterial: *Staphylococcus aureus,* erythrasma
- Lymphogranuloma venereum, granuloma inguinale, chancroid
- Molluscum contagiosum
- Herpes, gonococcal syphilis, human papillomavirus, trichomoniasis

Local irritants:
- Moisture, obesity, excessive perspiration
- Soaps, hygiene products
- Toilet paper: Perfumed, dyed
- Underwear: Irritating fabrics, detergents
- Anal creams, suppositories
- Dietary: Coffee, beer, acidic foods
- Drugs: Mineral oil, ascorbic acid, hydrocortisone sodium succinate, quinine, colchicine

Dermatologic diseases:
- Inverse psoriasis
- Atopic dermatitis
- Seborrheic dermatitis
- Hidradenitis suppurativa

Squamous cell carcinoma or adenocarcinoma
- Contact dermatitis

Section II also describes the various causes of pruritus ani.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Allergies
- Anxiety
- Dermatologic conditions
- Infections
- Parasites
- Diabetes mellitus
- Chronic liver disease
- Neoplasia
- Proctalgia fugax

WORKUP

- Detailed history regarding bowel habits, hygiene, use of perfumed products, changes in diet, and medical history
- Inspection of perianal area
- Possible biopsy to exclude neoplasia
- Palpation of inguinal lymph nodes (if present suggestive of neoplasia)
- Microscopic inspection of scrapings
- Colposcopy

LABORATORY TESTS

- CBC, comprehensive metabolic panel (CMP) thyroid stimulating hormone (TSH)
- Urinalysis
- Cultures
- Stool for ova and parasites
- Tape test
- HIV test if risk factors are present
- Glucose tolerance test, if necessary

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of tight, nonbreathable clothing and underclothing
- Discontinuation or curtailment of coffee, beer, citrus fruits, tomatoes, chocolate, and tea. Dietary modification is frequently recommended, although its effectiveness has not been established. Cleansing of anal area after bowel movements with a premoistened pad or tissue and avoidance of perfumes and dyes present in toilet paper and soaps
- Avoidance of excessive perspiration
- Aggressive management of fecal leakage or incontinence to avoid soiling of perianal skin

ACUTE GENERAL Rx

- Minimization of frequent loose stools with antidiarrheals and fiber agents if appropriate
- Use of a 1% hydrocortisone cream sparingly bid during the acute phase of pruritus ani but not for >2 wk to avoid atrophy
- Protective ointments such as zinc oxide may be helpful
- For nighttime symptoms, an antihistamine taken orally to help quell itching
- Treatment of predisposing factors, such as parasites, diabetes, liver disease, hemorrhoids, and other infections

CHRONIC Rx

- Possible complications: Excoriation and secondary bacterial infection; must be treated aggressively
- Longstanding, intractable pruritus ani: Good response to topical capsaicin (depletes substance P) or intracutaneous injections of methylene blue (kills nerve endings), or steroid injections

DISPOSITION

- Usually good results with total resolution of symptoms
- In some, persistent and recurrent symptoms—these patients should be carefully reassessed for an underlying cause, and may require additional laboratory testing

REFERRAL

To colorectal specialist if conservative measures fail or if patient experiences rectal bleeding or change in bowel movements

Pruritus Vulvae ALG

BASIC INFORMATION

DEFINITION

Pruritus vulvae refers to intense itching of the female external genitalia.

SYNONYMS

Lichen simplex chronicus
Atopic dermatitis
Squamous cell hyperplasia
Eczema

ICD-10CM CODES

L28.0 Lichen simplex chronicus
L29.2 Pruritus vulvae
L29.3 Anogenital pruritus, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- A disorder that can affect women at any age, including children.
- Lichen simplex is a common cause of itching in the anogenital area.
- Postmenopausal women: Frequently affected because of hypoestrogenic state (thinned skin is more susceptible to irritants).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Unrelenting, intense itching or burning of the vulva or anogenital skin.
- Scratching provides initial relief, but chronic scratching and rubbing exacerbates the sensation of itching.
- Itching can wake patients from sleep, and nighttime scratching is common.
- Physical findings often include erythema; erythematous plaques; papules; thickened, sometimes leathery-appearing skin; erosions and fissures from scratching; and pigment change (hyperpigmentation and hypopigmentation).

ETIOLOGY

- Severe pruritus is probably caused by triggering of terminal nerve fibers in a disrupted epidermal barrier layer (caused by inflammation, irritants, infection, scratching, etc.).
- The severe itching and skin changes in lichen simplex are the end result of chronic scratching and rubbing. This is in response to a number of initiating triggers, including environmental causes, infectious causes, and other underlying or associated skin conditions. Noninfectious causes of itching are more common in chronic itching. Environmental causes include heat, tight clothing, sweat, urine, moist toilet wipes, menstrual or urinary incontinence pads, panty liners, benzocaine, contraceptive gels, vaginal medications, feminine hygiene products, and soap.
- Infectious causes of itching include yeast, herpes simplex, condylomata acuminata, and molluscum contagiosum.
- Other causes:
  1. Neoplasms such as vulvar intraepithelial neoplasia (VIN), Paget disease, and squamous cell carcinoma
  2. Vulvar or vaginal atrophy
  3. Infestations with scabies, pediculosis pubis, or pinworms
- Children typically have nonspecific pruritus, lichen sclerosus, bacterial infections, or pinworm infestation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Contact or irritant dermatitis
- Vaginitis (yeast, trichomonas)
- Vulvar dermatoses, including lichen sclerosus, lichen planus, psoriasis
- VIN
- Pinworms
- Vulvar cancer
- Syringoma of the vulva

WORKUP

- Inspection of vulva and perianal area for skin texture change, erythema, papules, fissures, ulcerations, erosions, induration, or plaques.
- Must rule out infections, including trichomoniasis, candidiasis, and bacterial vaginosis with vaginal exam.

LABORATORY TESTS

- pH and wet prep of saline and potassium hydroxide of vaginal discharge
- Vaginal cultures
- Biopsy when needed (punch biopsy commonly used), especially if symptoms persist despite therapy, or if diagnosis is unclear
- Tape test to look for pinworms

TREATMENT

NONPHARMACOLOGIC THERAPY

- Stop scratching.
- Avoid excessive washing: Use plain water to gently wash.
- Wear loose-fitting clothing.
- Soak at comfortable temperature, and then apply barrier such as petrolatum or zinc oxide paste.
- Cool gel packs.
- Avoid perfumes; feminine hygiene products, including pads (if possible); benzocaine; antibiotic ointments; and body creams over vulvar area because they can cause irritation.
- Reduce stress and address psychological component.

ACUTE GENERAL Rx

- Local application of corticosteroids:
  1. One of the high- or medium-potency corticosteroids (such as 0.05% clobetasol ointment or 0.05% fluocinonide ointment) can be used to relieve itching.
  2. Apply to vulva twice daily for 2 to 4 wk, then once daily for 2 to 4 wk, and then three times weekly for 2 to 4 wk.
- Once itching is controlled, high-potency steroid can be discontinued and patient can be switched to hydrocortisone preparation to use intermittently.
- Stop itching and scratching, especially nighttime scratching, with hydroxyzine or diphenhydramine (1 to 25 mg, can increase to 50 mg) before bedtime.
- Selective serotonin reuptake inhibitors (SSRIs) may be helpful.
- Need to treat other underlying problems:
  1. Yeast infection: Any of the vaginal antifungal creams or fluconazole 150 mg every 3 days for three doses. Children and menopausal women not on estrogen are less likely to have yeast as cause.
  2. Trichomoniasis or bacterial vaginosis: Metronidazole 500 mg PO bid for 7 days.
  3. Antibiotics for superimposed infection—dicloxacillin 250 to 500 mg four times daily for 10 days, or treatment based on culture results.
  4. Urinary tract infection: Treatment of specific organism.
  5. Vaginal estrogen replacement therapy if atrophy is the cause of pruritus or burning.
  6. Pinworms: Mebendazole 100 mg 1 tablet at diagnosis and repeated in 1 to 2 wk; also treat other members in family aged >2 yr.
  7. Lichen sclerosus: High-potency topical steroid ointment such as clobetasol propionate ointment 0.05% applied twice daily until skin appearance/texture improves (several mo), and then can decrease to 3 times weekly.

CHRONIC Rx

- If not relieved by topical measures: Intradermal injection of triamcinolone (10 mg/ml diluted 2:1 saline); 0.1 ml of the suspension injected at 1-cm intervals and tissue gently massaged.
- If symptoms still uncontrollable: Consider systemic steroids, prednisone, or prednisolone, 40 mg daily for 7 days and then 20 mg daily for 7 days.

DISPOSITION

Usually controlled with conservative measures and topical steroids.

REFERRAL

- To a gynecologist for further workup if conservative measures do not give relief.
- When burning rather than itching predominates, the patient should be evaluated for vulvar dermatoses, vulvodynia, or signs of sensory neuropathy.

Psittacosis

BASIC INFORMATION

DEFINITION

Psittacosis is a systemic infection caused by the bacterium *Chlamydophila psittaci* (formerly known as *Chlamydia psittaci*) and is predominantly transmitted by birds.

SYNONYMS

Ornithosis
Parrot pneumonia

ICD-10CM CODE
A70 *Chlamydia psittaci* infections

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- In 2014, only eight cases were reported in the U.S. compared with an average of 10 cases (range 2 to 21) reported annually from 2005 to 2011. However, there was an outbreak of 13 cases in 2018 in Georgia and Virginia among poultry workers in two separate poultry slaughterhouses owned by the same corporation.
- True incidence is probably higher because infections may be subclinical.
- Highest incidence among pet owners and people working with birds.

PEAK INCIDENCE: Age 30 to 60 yr
PREVALENCE (IN U.S.):

- Low among humans.
- More than 130 avian species serve as hosts of the bacterium, and between 5% and 8% of birds, including poultry, seagulls, and geese, carry the organism.
- Most human infections are from birds of the order Psittaciformes, which includes cockatiels, parrots, cockatoos, and budgerigars.

PREDOMINANT SEX: Equal sex distribution
PREDOMINANT AGE: More common in adults

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation period of 5 to 15 days
- Subclinical infection
- Onset abrupt or insidious
- Most common symptoms:
  1. Fever
  2. Myalgias
  3. Chills
  4. Cough
- Most common clinical syndrome: Atypical pneumonia with fever, headache, dry cough, and a chest radiograph more dramatically abnormal than the physical examination
- Ranges from mild disease to respiratory failure and death, although this is extremely unusual
- Other clinical presentations:
  1. Mononucleosis-like syndrome
  2. Typhoidal form
- Most frequent physical findings:
  1. Fever
  2. Pharyngeal erythema
  3. Rales
  4. Hepatomegaly
- Less common findings:
  1. Somnolence
  2. Confusion
  3. Relative bradycardia
  4. Pleural rub
  5. Adenopathy
  6. Splenomegaly
  7. Horder spots (pink blanching maculopapular rash)
- Besides the lungs, other specific end-organ involvement:
  1. Pericarditis
  2. Myocarditis
  3. Endocarditis
  4. Hepatitis
  5. Joints
  6. Kidneys (glomerulonephritis)
  7. Central nervous system

ETIOLOGY

- *C. psittaci* is an obligate intracellular bacterium.
- Infection is usually spread by the respiratory route from infected birds, by direct contact or aerosolization of dried feces or bird feather dust, and rarely from a bite.
- There is a history of exposure to birds in 85% of patients, mostly with birds as pets.
- Strains from turkeys and psittacine birds are most virulent for human beings.
- Cows, goats, and sheep are occasionally implicated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- *Legionella*
- *Mycoplasma*
- *Chlamydophila pneumoniae*
- Viral respiratory infections
- Typhoid fever
- Viral hepatitis
- Aseptic meningitis
- Mononucleosis

WORKUP

- Complete blood count, and renal and liver function tests
- *Chlamydophila* serology
- Chest x-ray
- Special immunostaining of respiratory secretions

LABORATORY TESTS

- White blood count is normal or slightly elevated
- ESR and C-reactive protein are generally elevated
- Mild liver function abnormalities are common (50%)
- Blood cultures are almost always negative
- Highly infectious in cultures and thus a biohazard to laboratory workers, and so specialized laboratories are required
- Studies on respiratory secretions:
  1. Direct immunofluorescent antibody of respiratory secretions with monoclonal antibodies to chlamydial antigens
  2. *Chlamydophila* lipopolysaccharide antigen by enzyme immunoassay
  3. Polymerase chain reaction can be done on respiratory secretions and also possibly on blood, sputum, and even urine
- Serologic studies:
  1. Complement-fixing (CF) antibodies
  2. Microimmunofluorescence (MIF) antibody test: Specialty labs only
  3. Possible false-negative results and cross-reaction with other chlamydial species with both techniques

IMAGING STUDIES

- Chest x-ray is abnormal in 50% to 90% with a variety of patterns.
- Pleural effusions are common.

TREATMENT

ACUTE GENERAL Rx

- Doxycycline (100 mg PO bid) for 10 to 14 days after fever declines *or*
- Tetracycline (500 mg PO qid)
- Macrolides, such as erythromycin or azithromycin, are considered second-line agents in adults but first-line agents in children
- Quinolones, such as ciprofloxacin and moxifloxacin, are effective in vitro, but more studies are needed for clinical use

CHRONIC Rx

In the rare cases of endocarditis, combination of heart valve replacement and prolonged antibiotic course may be the treatment of choice.

DISPOSITION

- Mortality rate is low (0.7%)
- Poor prognostic factors:
  1. Advanced age
  2. Leukopenia
  3. Severe hypoxemia
  4. Renal failure
  5. Confusion
  6. Multilobe pulmonary involvement
- Possible reinfection

REFERRAL

- To infectious disease expert:
  1. Complicated atypical pneumonia or other end-organ involvement
  2. Suspicion of an outbreak
- To pulmonologist for diagnostic bronchoscopy

PEARLS & CONSIDERATIONS

COMMENTS

- Hospitalized patients do not require specific isolation precautions.
- Any confirmed or suspected case of psittacosis should be reported to public health authorities.
- Recent evidence indicates that *C. psittaci* may be associated with induction of a rare form of lymphoma found in the ocular adnexa; case reports have described regression of ocular lymphoma with antibiotic treatment for *C. psittaci.*

BASIC INFORMATION

DEFINITION

Psoriasis is a chronic skin disorder characterized by excessive proliferation of keratinocytes, resulting in the formation of thickened scaly plaques, itching, and inflammatory changes of the epidermis and dermis. Psoriasis is also associated with cardiovascular, metabolic, and neuropsychiatric effects. The various forms of psoriasis include plaque (most common), guttate, erythrodermic, pustular, inverse, and arthritis variants.

ICD-10CM CODES

L40	Psoriasis
L40.0	Psoriasis vulgaris
L40.1	Generalized pustular psoriasis
L40.4	Guttate psoriasis
L40.8	Other psoriasis
L40.9	Psoriasis unspecified
L40.54	Psoriatic juvenile arthropathy

EPIDEMIOLOGY & DEMOGRAPHICS

- Psoriasis affects 2% to 4% of the world's population. Most patients have limited psoriasis involving <5% of their body surface.
- There is a strong association between psoriasis and human leukocyte antigens (HLAs) B13, B17, and B27 (pustular psoriasis).
- Peak age of onset is bimodal (age 30 to 39 yr and at age 60 yr). Mean age at diagnosis is 34 yr.
- Men and women are affected equally. Approximately 20% of patients with psoriasis also have psoriatic arthritis. Median time from development of joint symptoms to diagnosis of psoriatic arthritis is 5 yr. Nail psoriasis affects over 50% of patients with psoriasis and can occur with any of the subtypes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Approximately 85% of patients with psoriasis have mild-to-moderate disease.
- The primary psoriatic lesion is an erythematous papule topped by a loosely adherent scale. Scraping the scale results in several bleeding points *(Auspitz sign).*
- Chronic plaque psoriasis generally manifests with symmetric, sharply demarcated, erythematous, silver-scaled patches affecting primarily the intergluteal folds, elbows, scalp, fingernails, toenails, and knees (Figs. 1 and 2). This form accounts for 80% of psoriasis cases. Psoriasis may also involve the forehead, particularly contiguous to the scalp (Fig. E3).
- Psoriasis can also develop at the site of any physical trauma (sunburn, scratching). This is known as *Koebner phenomenon.*
- Nail involvement is common (pitting of the nail plate), resulting in hyperkeratosis, onychodystrophy with onycholysis (Fig. E4).
- Pruritus is variable; soreness and bleeding may occur.
- Joint involvement can result in sacroiliitis and spondylitis.
- Guttate psoriasis is generally preceded by streptococcal pharyngitis and manifests with multiple droplike lesions on the extremities and the trunk.
- Erythrodermic psoriasis is characterized by widespread cutaneous erythema and scaling.
- Pustular psoriasis manifests with widespread pustules. Localized forms may affect palms and soles.
- Inverse psoriasis is characterized by red and sharply demarcated thinner patches involving intertriginous areas (axillae, inguinal areas).
- Adverse effect on psychological and social functioning, with affected persons often feeling stigmatized.

ETIOLOGY

- Unknown, but there is a strong genetic component and high heritability. There are at least nine chromosomal loci with linkage to psoriasis. These loci are called psoriasis susceptibility 1 through 9 (PSORS1-PSORS9). PSORS1 locus in the major histocompatibility complex (MHC) region on chromosome 6 is considered the most important susceptibility locus and is believed to account for 35% to 50% of the heritability of the disease.
- Familial clustering (genetic transmission with a dominant mode with variable penetrants).
- One third of persons affected have a positive family history.
- A high prevalence of celiac disease has been noted in patients with psoriasis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Contact dermatitis
- Atopic dermatitis
- Stasis dermatitis
- Tinea
- Nummular dermatitis
- Candidiasis
- Mycosis fungoides, Sezary syndrome
- Cutaneous systemic lupus erythematosus
- Secondary and tertiary syphilis
- Drug eruption
- Dermatomyositis (DM)

FIG. 1 Psoriasis. Variably sized erythematous plaques with moderately thick overlying scale. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. 2 Typical plaques of psoriasis with thick, micaceous scale overlying erythema. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

- Lupus erythematosus (LE)
- Seborrheic dermatitis
- Pityriasis rosea
- Lichen planus
- Pityriasis rubra pilaris

WORKUP

- Diagnosis is clinical. Blood work is rarely needed. A rapid plasma regain test is useful when ruling out syphilis. Antinuclear antibody (ANA) and anti-Ro and anti-La antibodies are helpful in ruling out subacute cutaneous lupus.
- Skin biopsy is rarely necessary.

LABORATORY TESTS

Generally not necessary for diagnosis

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Sunbathing generally leads to improvement.
- Eliminate triggering factors (e.g., stress, certain medications [e.g., lithium, beta-blockers, antimalarials]). Severe emotional stress tends to aggravate psoriasis.
- Patients with psoriasis benefit from a daily bath in warm water followed by application of a cream or ointment moisturizer. Regular use of an emollient moisturizer limits evaporation of water from the skin and allows the stratum corneum to rehydrate itself.
- Psoralen and ultraviolet A (PUVA) therapy (see "General Rx").
- Local hyperthermia has been used successfully to clear psoriatic plaques, but relapse is common.
- Occlusive treatment with surgical tape or dressings is effective as monotherapy or in combination with topical medications.
- Avoidance of tobacco. Smoking tobacco may worsen psoriasis.

GENERAL Rx

Therapeutic options vary according to the extent of disease. Approximately 70% to 80% of all patients can be treated adequately with topical therapy.

- Patients with limited disease (<20% of the body) can be treated with the following:
  1. Topical steroids: Disadvantages are brief remissions, expense, and decreased effect with continued use. Salicylic acid can be compounded by pharmacist in concentrations of 2% to 10% and used in combination with a corticosteroid to decrease the amount of scale.
  2. Calcipotriene: A vitamin D analogue effective for moderate plaque psoriasis. Adults should comb the hair, apply solution to the lesions, and rub it in, avoiding uninvolved skin. Disadvantages include its cost and potential burning and skin irritation. It should not be used concurrently with salicylic acid because calcipotriene is inactivated by the acidic nature of salicylic acid. Taclonex ointment and Enstilar aerosol foam formulation are a combination of calcipotriene and the high-potency corticosteroid betamethasone dipropionate. They are well tolerated and more effective than either agent used alone but also much more expensive.
  3. Tar products (Estar, liquor carbonis detergens [LCD], Psorigel) can be used overnight and are most effective when combined with ultraviolet B (UVB) light (Goeckerman regimen).
  4. Anthralin: Useful for chronic plaques; can result in purple-brown staining; best used with UVB light.
  5. Retinoids such as tazarotene 0.05%, 0.1% cream or gel, are effective in thinning plaques but are expensive and can cause irritation.
  6. Other useful measures include tape or occlusive dressing, UVB and lubricating agents, and interlesional steroids.
- Therapeutic options for persons with generalized disease (affecting >20% of the body) and for those with inadequate response to topical agents:
  1. UVB light exposure three times a wk: This therapy does not require administration of a systemic drug (unlike psoralen plus ultraviolet A [PUVA]), but to be effective, it requires removal of scale with keratolytic agents and emollients.
  2. Oral PUVA administered two to three times weekly is effective for generalized disease. It is often considered in patients for whom narrow-band UVB therapy is ineffective. However, many PUVA treatments are required, necessitating frequent office visits, and it may be associated with phototoxicity, such as erythema and blistering, and increased risk of skin cancer.
- Systemic treatments include methotrexate 25 mg/wk for severe psoriasis. Etretinate (a synthetic retinoid) is most effective for palmar-plantar pustular psoriasis. Dose is 0.5 to 1 mg/kg/day. It can cause liver enzyme and lipid abnormalities and is teratogenic.
- Apremilast is a phosphodiesterase type-4 inhibitor used in moderate to severe plaque psoriasis. Side effects include diarrhea, nausea, headache, and worsening depression.
- Cyclosporine is also effective in severe psoriasis; however, relapses are common.
- Chronic plaque psoriasis may be treated with alefacept, a recombinant protein that selectively targets T lymphocytes. Treatment with alefacept for 12 wk (0.025, 0.075, or 0.150 mg/kg of body weight IV weekly) may result in significant improvement. Some patients also demonstrate a sustained clinical response after the cessation of treatment. This medication is very expensive (a 12-wk course can cost >$8000).
- Biologic therapies are now routinely used when traditional systemic agents are ineffective or poorly tolerated. Screening for tuberculosis is necessary before initiating treatment with these agents. Active, serious infection is a contraindication to the use of biologics.
- Tumor necrosis factor (TNF) inhibitors (adalimumab [Humira], etanercept [Enbrel], infliximab [Remicade]): Trials revealed a reduction in severity of plaque psoriasis. Efalizumab, a humanized monoclonal antibody that inhibits the activation of T cells, has also been reported to produce significant improvement in plaque psoriasis treatment period. Adalimumab has been reported to be effective for joint and skin manifestations of psoriasis.
- Newer biologic agents in patients with moderate to severe plaque psoriasis are ustekinumab (Stelara; an interleukin-12 and interleukin-23 blocker), brodalumab (SILIQ), ixekizumab (Taltz), secukinumab (Cosentyx) anti–interleukin-17 receptor antagonists, and guselkumab (Tremfya), risankizumab (Skyrizi), and tildrakizumab (ILUMYA) interleukin-23 blockers. Cost is a limiting factor with all these agents.

DISPOSITION

The course of psoriasis is chronic, and the disease may be refractory to treatment.

REFERRAL

- Dermatology referral is recommended in all patients with generalized disease.
- Hospital admission may be necessary for severe diffuse or poorly responsive psoriasis. The Goeckerman regimen combines daily application of tar with UVB exposure and can result in prolonged remissions.

PEARLS & CONSIDERATIONS

COMMENTS

Psoriasis is more emotionally than physically disabling for most patients. Counseling may be indicated, particularly when it affects younger patients.

FIG. E3 Psoriasis often involves the forehead, particularly contiguous to the scalp. Note the eyelid and brow involvement. Given the yellowish scaling, this has been called "sebopsoriasis." (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

FIG. E4 Nail psoriasis. Several fingers show severe onycholysis with oil spots and nail pitting, accentuated where the pits trapped old nail polish. Having just a few nails involved is common. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Psoriatic arthritis (PsA) is an inflammatory arthropathy, often included in a class of disorders called the *seronegative spondyloarthropathies (SpA),* a family of diseases characterized by inflammation of the spine, peripheral joints, and entheses (sites of insertion of tendon into bone). Both the Moll and Wright and CASPAR classification criteria are described in Table1.

ICD-10CM CODES

L40.5+	Arthropathic psoriasis
L40.54	Psoriatic juvenile arthropathy
L40.52	Psoriatic arthritis mutilans

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 6 per 100,000 per yr
PREVALENCE: One to two per 1000 in the general population. Variable estimates of 4% to 30% of patients with underlying psoriasis
PREDOMINANT SEX: Equal male-to-female distribution
PREDOMINANT AGE: Symptom onset generally between age 30 to 55

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Psoriasis precedes arthritis in 67% of cases by an average of 8 to 10 yr.
- Arthritis precedes psoriasis or occurs concomitantly in 33% of patients.
- Arthritis, dactylitis, spondylitis, and enthesitis are main features.
- On examination, about 15% of patients will have psoriasis without prior diagnosis of skin disease.
- Arthritis is inflammatory, commonly characterized by prolonged morning stiffness, improvement with activity, joint erythema, warmth, or swelling.
- There are five classically described patterns of joint involvement (Box 1).
- Some patients may present with more than one pattern, and patterns can evolve over time. The distal interphalangeal (DIP) joints (Fig. E1) and spine are each affected in 40% to 50% of cases. It is rare to have spondyloarthritis alone, and it usually occurs with peripheral involvement.
- Dactylitis, also known as "sausage digit," refers to diffuse swelling of a finger or toe (Fig. E2); it is fairly common and occurs in approximately 30% to 40% of patients during the disease course. It is associated with increased risk of radiographic joint damage.
- Enthesitis commonly occurs at the Achilles and plantar fascia (Fig. E3), and swelling and tenderness may be seen on exam. Subclinical disease may be evident by ultrasonography.
- Dystrophic changes of the nails (pitting, onycholysis, leukonychia) may occur in association with joint inflammation in involved digits.
- Spondyloarthritis may include sacroiliitis but is generally less likely to cause fusion to the extent seen in ankylosing spondylitis. More common to have asymmetric sacroiliac joint involvement (usually bilateral in ankylosing spondylitis).
- Ocular inflammation including conjunctivitis and uveitis can be seen.

ETIOLOGY

Remains unknown, but felt to be interplay of genetic, immunologic, and environmental factors. Fig. E4 illustrates the pathogenetic pathways in PsA. There is a higher frequency of HLA-B12, HLA-B17, HLA_B57, HLA-Cw*0602 in PsA. Those with PsA versus psoriasis alone have higher frequency of HLA-B7, HLA-B27.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rheumatoid arthritis (RA)
- Erosive osteoarthritis
- Crystalline arthritis, including gout and pseudogout
- Other seronegative spondyloarthropathies, which include reactive arthritis, enteropathic arthritis, and ankylosing spondylitis (also see differential diagnosis of SpA in Section III)

WORKUP

- Diagnosis is generally made on clinical grounds based on history, exam, and radiographic findings given lack of specific lab findings. An algorithm for the diagnosis of psoriatic arthritis is described in Fig. 5.
- Early diagnosis can be difficult to establish when the joint symptoms develop before skin and nail findings.

LABORATORY TESTS

- No specific diagnostic lab tests.
- Acute phase reactants such as ESR and CRP may be elevated, although less commonly than in patients with rheumatoid arthritis.
- Anemia of chronic disease may be seen.
- Rheumatoid factor (RF) and anti-CCP are generally negative but can be present in up to 15% of patients.
- *HLA-B27* is significantly more common in patients with axial inflammation.
- Arthrocentesis generally demonstrates inflammatory synovial fluid without crystals.

BOX 1 Subtypes of Psoriatic Arthritis

- Distal interphalangeal joint–predominant arthritis (10%)
- Symmetric polyarthritis–predominant arthritis (5%-20%)
- Asymmetric oligoarthritis or monoarthritis (70%-80%)
- Axial disease predominant (spondylitis, sacroiliitis, or both) (5%-20%)
- Arthritis mutilans (rare)

From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

TABLE 1 Classifications of Psoriatic Arthritis

	CASPAR*		
Moll and Wright	**Points**	**Category**	**Description**
Presence of PsO and an inflammatory arthritis (peripheral arthritis and/or sacroiliitis or spondylitis)	2	Current PsO	Psoriatic skin or scalp disease confirmed by a dermatologist or rheumatologist; history of PsO from the patient, family physician, dermatologist, rheumatologist, or other qualified practitioner; patient-reported history of PsO in a first- or second-degree relative
	1	Personal or family history of PsO	
The (usual) absence of serologic tests for RF	1	Psoriatic nail dystrophy on current physical examination	Includes onycholysis, pitting, and hyperkeratosis
	1	Negative test for RF	ELISA or nephelometry preferred (no latex) using the local laboratory reference range
	1	Current dactylitis or history of dactylitis documented by a rheumatologist	Swelling of the entire digit
	1	Radiographic evidence of juxtaarticular new bone formation	Ill-defined ossification near joint margins in the hand or foot, excluding osteophyte formation on plain radiographs

*Psoriatic arthritis is diagnosed when three or more points are assigned in the presence of inflammatory articular disease (joint, spine, or entheseal).
CASPAR, Classification Criteria for the Study of Psoriatic Arthritis; *ELISA,* enzyme-linked immunosorbent assay; *PsO,* psoriasis; *RF*, rheumatoid factor.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

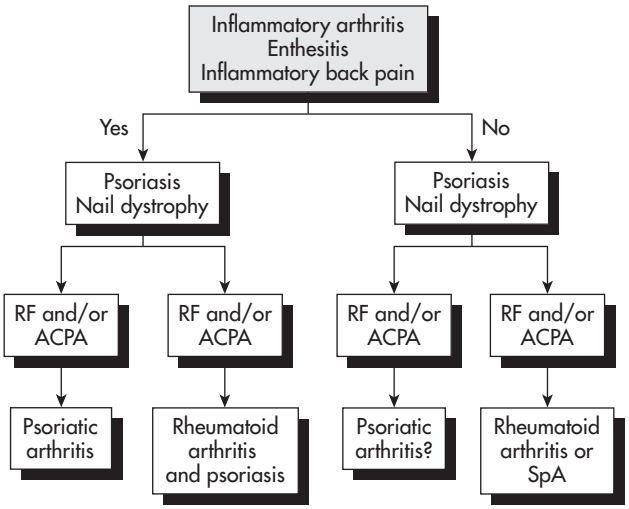

FIG. 5 Algorithm to be used in the diagnosis of individual patients presenting with possible psoriatic arthritis. Some patients may present with typical articular manifestations of psoriatic arthritis but in the absence of skin or nail disease. They can be diagnosed as having definite psoriatic arthritis only when psoriasis subsequently develops. *ACPA,* Anticitrullinated protein antibody; *RF,* rheumatoid factor; *SpA,* spondyloarthropathy. (From Firestein GS et al: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

IMAGING STUDIES

Radiographic findings of involved joints may include soft tissue swelling, joint space narrowing, subluxation, erosive changes, and new bone formation (periostitis, fusion). As opposed to RA, see more asymmetric joint involvement and DIP joint changes.

Severe digital erosive change with adjacent heterotopic bone formation may give rise to "pencil in cup" deformity. Can see whittling of the phalanges.

With axial involvement can see sacroiliac joint changes (sclerosis, erosions, pseudo-widening, ankylosis) and bridging vertebral syndesmophytes.

Musculoskeletal ultrasonography can be used in the evaluation of enthesitis or arthritis.

MRI may be helpful in further evaluation of sacroiliac and spinal involvement.

Rx TREATMENT

PHARMACOLOGIC THERAPY

The choice of therapeutic agent depends on the type of clinical manifestations, as not all agents are effective for all manifestations. For example, enthesis and spinal involvement are not responsive to traditional oral disease-modifying agents such as methotrexate or leflunomide but are responsive to tumor necrosis factor blocking agents (TNFi).

- NSAIDs may be used for mild or limited disease.
- Intraarticular corticosteroid injections can be used as adjunctive rx for involved joints.
- Oral glucocorticoids should generally be avoided, given increased risk for development of erythrodermic or pustular psoriasis.
- In patients with active peripheral joint disease, elevated acute phase reactants, or evidence of changes on imaging, traditional DMARDs such as methotrexate, sulfasalazine, and leflunomide should be considered early on, though data supporting their use is limited.
- Apremilast is an oral phosphodiesterase 4 (PDE 4) inhibitor and is safe to use, especially in those with multiple comorbidities. Can also be beneficial for enthesitis and dactylitis.
- In patients with peripheral arthritis who fail to respond to nonbiologic DMARDs, escalation of therapy should be considered. All five TNFi are FDA-approved to treat psoriatic arthritis (etanercept, infliximab, adalimumab, golimumab, certolizumab pegol). In those resistant to a TNFi, a second TNFi can be tried. If adequate response is still not achieved, a different mechanism of action (IL-17i, IL-12/23 blockade) can be tried.
- Secukinumab, an IL-17 inhibitor, is approved to treat psoriasis, PsA, and AS. Ixekizumab, an anti-IL-17 monoclonal antibody, can also be used to treat psoriasis, PsA, and now AS. Brodalumab, an anti-IL17RA monoclonal antibody, treats psoriasis alone currently. Guselkumab, an anti-IL23 antibody, is also only approved for psoriasis.
- Ustekinumab is a human IgG monoclonal antibody that binds to the p40 subunit of interleukin (IL)-12 and -23 and is approved to treat psoriasis, psoriatic arthritis, and Crohns.
- Abatacept (selective T-cell costimulation modulator) was approved to treat PsA, but has shown limited efficacy in treatment of psoriasis but can help peripheral arthritis. Tofacitinib (oral Janus kinase inhibitor) has also been approved.
- In patients with predominantly axial disease not responsive to NSAIDs, TNFi or IL17i can be tried. For enthesitis/dactylitis TNFi, IL17i, IL12/23, and apremilast can be considered.

REFERRAL

Rheumatology, dermatology

PEARLS & CONSIDERATIONS

- Patients frequently have a positive family history of psoriasis or psoriatic arthritis.
- Severity of skin psoriasis and activity of inflammatory arthritis can be discordant.

BASIC INFORMATION

DEFINITION

Psychosis is a state in which external reality is distorted by delusions and/or hallucinations (a delusion is a fixed false idiosyncratic belief; a hallucination is a false auditory, visual, olfactory, tactile, or taste perception).

Psychosis is a key finding in many mental illnesses, such as brief psychotic disorder, delusional disorder, schizoaffective disorder, schizophrenia, schizophreniform disorder, or shared psychotic disorder. Psychosis can also present as part of the evolution of a mood disorder (depression and bipolar disorder), a sign of an underlying medical condition, or a manifestation of a toxic state, i.e., abuse of substances or withdrawal state.

ICD-10CM CODES	
F05	Delirium not induced by alcohol and other psychoactive substances
F06.0	Organic hallucinosis
F09	Unspecified organic or symptomatic mental disorder
F10.5	Psychotic disorder due to psychoactive substance use
F30.2 and F31.2	Manic episode with psychosis and bipolar affective disorder with psychosis
F32.3	Major depressive disorder, single episode, severe with psychotic features
DSM-5 CODES	
Depends on specific diagnosis	

EPIDEMIOLOGY & DEMOGRAPHICS

1-yr prevalence: 4.5 per 1000. The (demographics of) psychosis depends on the underlying disorder.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

History:

- Past and current medical history important to identify potential medical etiologies
- Medication use
- Use of illicit substances or alcohol
- Identification of functional and social impairment
- Behavior that is odd or unpredictable; patient may be acting based on misinterpretation of their reality or false perceptions (delusions or hallucinations)

Examination:

- Examine for symptoms of:
  1. Mood disorder: Delusions or hallucinations are usually congruent with the mood (e.g., auditory hallucinations in a depressed patient may tell the patient what a terrible person he is)
  2. Altered or disorganized thought pattern: Usually reflected in disorganized speech (including word salad, thought blocking, rhyming, clang associations) or disorganized behavior
  3. Lack of insight into problems
  4. Signs of Parkinson disease, dementia

ETIOLOGY

- Involves an interaction among:
  1. Dopaminergic overactivity (particularly in the mesocortical, mesolimbic, and nigrostriatal systems)
  2. Environmental, social, or childhood factors
  3. Genetic predisposition

DIAGNOSIS

WORKUP

- Evaluate for potential confounding factors
- Underlying mental disorder: Schizophrenia, major depression, brief psychotic disorder, delusional disorder, schizoaffective disorder, schizophreniform disorder
- Underlying personality disorder: Borderline, paranoid, schizoid, schizotypal
- Underlying medical conditions: Infections ranging from urinary tract infections (UTIs) to HIV/AIDS, Parkinson disease, Huntington disease, leprosy, malaria, sarcoidosis, systemic lupus erythematosus, prion disease, hypoglycemia, postpartum state, cerebrovascular event, temporal lobe epilepsy, brain neoplasm
- Medications: Systemic steroids, anticonvulsants, antiparkinsonian medications, some chemotherapy, scopolamine
- Underlying dementia: Alzheimer disease, Lewy body dementia, vascular dementia
- Illicit drugs (usually with chronic use; can be caused by intoxication or withdrawal): lysergic acid diethylamide (LSD), phencyclidine (PCP), cocaine, gamma-hydroxybutyrate (GHB; withdrawal), alcohol, amphetamines, and marijuana. New substances of abuse (e.g., "bath salts," synthetic cannabinoids) may not be detected by current toxicology panels
- Traumatic brain injury
- Intensive care unit stay: Hypoxia, decreased cardiac output, infection, medications, sleep deprivation, alteration of diurnal cycle, sensory deprivation or overload, pain
- Emotional stress

LABORATORY TESTS

Consider checking chemistry panel (calcium), complete blood count, UA, liver function tests, cortisol, HIV, rapid plasma reagin, thyroid-stimulating hormone, vitamin B_{12} and folate levels, indirect unconjugated bilirubin, serum antinuclear antibody (ANA), serum angiotensin converting enzyme, toxicology screen, lumbar puncture (LP).

IMAGING STUDIES

Consider chest x-ray (rule out sarcoid), electroencephalography, head CT or MRI.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cognitive-behavioral therapy
- Social and behavioral skills training
- Training for self-management of disease
- Aforementioned strategies favored over psychoanalytic techniques given the relative inability for abstract thought and lack of insight in psychotic patients
- Family intervention, including education and strategies to reduce emotional expression
- Counseling for substance abuse

ACUTE GENERAL Rx

- Antipsychotics (first or second generation equally effective but different in side effect profile) consider combining with anticholinergics like benztropine to reduce motor side effects if such arise; low doses should control first episode. Use with caution in elderly patients because adverse effects limit effectiveness. Second-generation antipsychotics are also useful starting with low doses. Alternative formulations are available; e.g., rapid injectable form or oral disintegrating tablets. Obtain baseline lab work including lipid profile, glucose/A1c, CBC.
- Benzodiazepines for nonspecific sedation if agitation is severe.
- Discontinue offending medication if present.

CHRONIC Rx

Second-generation antipsychotics may reduce the incidence of tardive dyskinesia but may increase incidence of metabolic disorders compared with first-generation antipsychotics. Multicenter trials showed similar efficacy between first and second generation. Consider economic factors, including insurance formulary, when selecting a maintenance regimen.

DISPOSITION

Prognosis varies according to etiology of psychosis. In general, the more severe and longer the psychotic episode, the worse the prognosis.

REFERRAL

Patient should be admitted for acute stabilization if actively psychotic to prevent harm to self and others as well as ensure administration of medications.

PEARLS & CONSIDERATIONS

- Delusions and/or hallucinations are hallmarks of psychosis.
- Rule out medical or drug causes of psychosis.
- Antipsychotics are the mainstay of acute and chronic treatment.
- Brief psychotic disorder DSM-5 298.8 (F23) (brief reactive psychosis), which is a psychotic response to a severe stressor, usually responds well to low-dose neuroleptic treatment.
- Consider alternatives to antipsychotics in elderly or intellectually disabled patients (see "Nonpharmacologic Therapy").

BASIC INFORMATION

DEFINITION

Acute cardiogenic pulmonary edema (ACPE) is a clinically observed consequence of increased capillary leakage of fluid into the interstitial space in the pulmonary vasculature, resulting in the constellation of clinical signs and symptoms of decreased gaseous exchange in the alveoli.

SYNONYMS

Cardiogenic pulmonary edema (CPE)
Acute cardiogenic pulmonary edema (ACPE)
Acute decompensated heart failure (ADHF) with pulmonary edema
Acute diastolic heart failure with pulmonary edema
Acute systolic heart failure with pulmonary edema

ICD-10CM CODES

I50.1	Left ventricular failure
J68.1	Pulmonary edema due to chemicals, gases, fumes and vapors
J81.0	Acute pulmonary edema
J81.1	Chronic pulmonary edema

EPIDEMIOLOGY & DEMOGRAPHICS

- The prevalence of heart failure (HF) is estimated around 6.5 million people and is expected to increase to 8 million by the yr 2030.
- In 2012, 1.7 million HF-related visits to U.S. physician offices, and half a million emergency department visits were reported.
- Within 30 days, 25% to 30% of these patients are readmitted with recurrent ADHF.
- In-hospital mortality rate is 10% to 20%, particularly when associated with acute MI.

CLINICAL PRESENTATION

- Altered mental status
- Dyspnea (exertional or at rest, paroxysmal nocturnal dyspnea, orthopnea)
- Cough and wheezing (cardiac asthma)
- Diaphoresis, cold and clammy skin
- Perioral and peripheral cyanosis
- Pink, frothy sputum

PHYSICAL EXAMINATION FINDINGS

- Hypertension (in cardiogenic shock could be hypotensive)
- Tachycardia
- Elevated jugular venous pressure with hepatojugular reflex
- Bilateral pulmonary rales/decreased or absent air entry
- S3 gallop/S4 and or laterally displaced apex
- Abdominal distention/ascites
- Peripheral edema
- Weight gain

ETIOLOGY

Common causes of acute pulmonary edema include the following:

- Acute myocardial infarction
- Poor dietary compliance or medication nonadherence
- Atrial and ventricular arrhythmias
- Valvular heart disease (mitral, aortic, tricuspid, and pulmonary valve disease)
- Renal and liver disease
- Endocrine (thyrotoxicosis, obesity, metabolic syndrome, diabetes)
- Toxin mediated (cocaine, alcohol, chemotherapy agents, ephedra)
- Peripartum cardiomyopathy/heart failure of pregnancy
- Infections (myopericarditis, endocarditis, HIV, Chagas)
- Uncontrolled hypertension
- Structural heart disease (ventricular septal defect, infiltrative heart disease, hypertrophic cardiomyopathy)
- Pulmonary embolism
- Box 1 summarizes common causes of cardiogenic and noncardiogenic pulmonary edema

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Noncardiogenic pulmonary edema (see Fig. E1 and Table 1)
- Viral pneumonitis and other pulmonary infections
- Pulmonary embolism
- Exacerbation of asthma/chronic obstructive pulmonary disease
- High altitude pulmonary edema (HAPE)
- Sarcoidosis
- Pulmonary fibrosis
- Lymphangitic carcinomatosis

BOX 1 Common Causes of Cardiogenic and Noncardiogenic Pulmonary Edema

Cardiogenic Pulmonary Edema
- Acute exacerbation of heart failure
- Acute valve dysfunction (e.g., mitral valve chordae tendineae rupture)
- Arrhythmia/myocardial infarction
- Hypertensive crisis
- Fluid overload following aggressive volume resuscitation (e.g., postoperative)
- Ventricular septal rupture
- Pericardial tamponade

Noncardiogenic Pulmonary Edema
- Direct lung injury
  - Pneumonia
  - Gastric aspiration
  - Toxic inhalation
  - Negative pressure related (e.g., strangulation)
- Indirect causes of lung injury
  - Sepsis
  - Trauma
  - Pancreatitis
  - Multiple blood transfusions
  - Burn injury

From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.

LABORATORY TESTS

- Arterial blood gases (ABGs): Respiratory and metabolic acidosis, decreased Pa_{O_2}, increased Pa_{CO_2}, low pH. (NOTE: The patient may initially show respiratory alkalosis as a result of hyperventilation in attempts to maintain Pa_{O_2}.)
- BNP and NT-pro BNP add diagnostic value to the history and physical examination as evidenced in the Breathing Not Properly (BNP) study.
- Cardiac biomarkers: Troponin T or I if suspicion for acute coronary syndrome.
- Basic metabolic profile: Assess for electrolyte abnormalities; renal failure can dictate diuretic choice.
- Complete blood count: Anemia can trigger acute pulmonary edema.
- Glucose, Hb A1C, fasting lipid profile, TSH for risk stratification.
- Urinalysis and urine toxicology if indicated.

IMAGING STUDIES

- ECG: May elucidate the specific cause of the pulmonary edema. Causes may include ischemia/infarct, arrhythmias, LV hypertrophy, atrial enlargement.
- Chest x-ray (Fig. 2):
  1. Bilateral interstitial and alveolar infiltrates
  2. Cephalization of the pulmonary vessels
  3. Kerley B lines; fluffy perihilar infiltrates
  4. Pleural effusions
  5. Enlarged cardiac silhouette
- Echocardiogram:
  1. Assess left and right ventricular systolic/diastolic function.
  2. Structural abnormalities (VSD, LV rupture).
  3. Evaluate valvular abnormalities.
  4. Engorged inferior vena cava (IVC) and IVC plethora, based on bedside ultrasound, suggests elevated filling pressures.
- Computed tomography of the chest; may differentiate between cardiogenic and noncardiogenic pulmonary edema.
- Right heart catheterization (RHC): Helps to differentiate between different types of shock and to guide tailored therapy (inotrope and pressor infusion) in cardiogenic shock. The ESCAPE trial failed to demonstrate the utility of pulmonary artery catheters in acute decompensated heart failure.
- Lung ultrasound has emerged as a tool to diagnose pulmonary edema. It is easy to use, accessible, noninvasive, and has a high accuracy. B lines and pleural effusions are suggestive of pulmonary edema.

TREATMENT

ACUTE GENERAL Rx (FIG. 3)

Nonpharmacologic treatment:

- Heart failure teaching.
- Sodium restriction in ACC/AHA class C and D heart failure patients has conflicting data.
- Restrict 1.5 to 2 L of free water in the setting of hyponatremia.

TABLE 1 Distinguishing Cardiogenic and Noncardiogenic Pulmonary Edema

	History	Exam	Labs	Imaging	Pulmonary Artery Catheter
Cardiogenic	Heart disease Renal disease Uncontrolled HTN Edema Orthopnea Recent administration of IV fluids or blood products	Heart failure exam findings: Distended neck veins S3 heart sound Dependent edema Elevated blood pressure Cool extremities	↑BNP >1200 pg/ml ↑Creatinine (in setting of volume overload) ↑Troponin	CXR: CMG Pleural effusions Kerley B lines TEE: ↓LVEF Diastolic filling defect Severe mitral or aortic valvular disease Pericardial effusion with tamponade VSD	PCWP >18 mm Hg Prominent V-waves (mitral regurgitation) Elevation and equilibration of right atrial pressure, pulmonary artery diastolic and PCWP (tamponade physiology) CVP >12 mm Hg

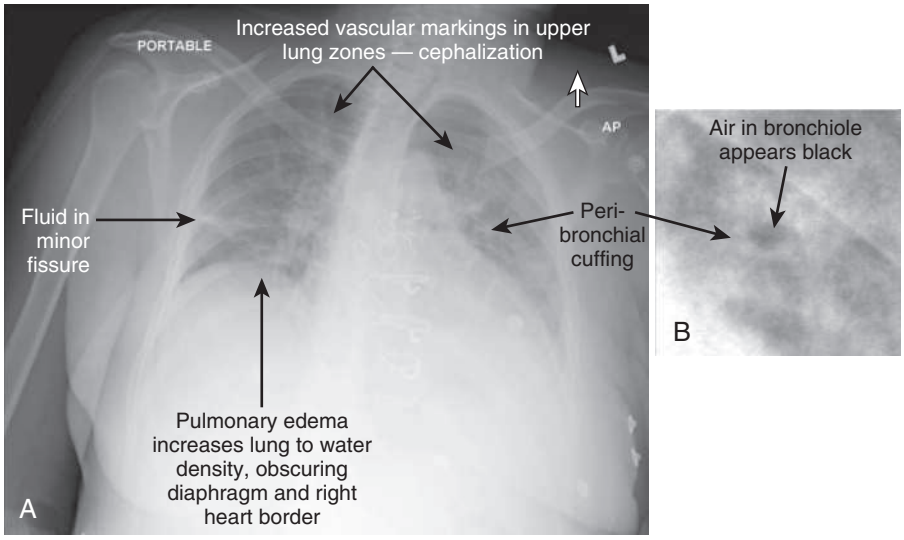

FIG. 2 Pulmonary edema. A, Anterior-posterior chest x-ray. **B,** Close-up from **A.** This 53-yr-old female with end-stage renal disease missed dialysis and presented to the emergency department. Her examination demonstrated bilateral rales. Her x-ray shows mild cardiomegaly, bilateral interstitial opacities, and cephalization of the pulmonary vascular markings. The minor fissure appears thickened. These findings are consistent with pulmonary edema. In addition, peribronchial cuffing is present. As discussed elsewhere, this is a nonspecific thickening of the bronchial wall that can occur from edema in the setting of heart failure, asthma, viral illness, or even infections such as pertussis. The thickened wall appears white, whereas the air-filled bronchiole appears black and has a circular short-axis cross section. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

- Risk factor modification (blood pressure and sugar control).
- Oxygen supplementation if signs of hypoxia are present.
- Noninvasive ventilation (continuous positive airway pressure [CPAP]) or bilevel noninvasive positive-pressure ventilation [NPPV]) reduces dyspnea and may reduce the need for endotracheal intubation. They improve oxygenation and lower carbon dioxide. Positive pressure ventilation (invasive or noninvasive) decreases preload and afterload and reduces the work of breathing, while positive end expiratory pressure improves oxygenation.

Pharmacologic treatment-afterload reducers:

- Loop diuretics such as furosemide, torsemide, bumetanide, and ethacrynic acid are the cornerstones of the treatment of volume overload. Intravenous treatment might be required in acute pulmonary edema. There is no difference in symptoms or kidney function whether the diuretic is given as a bolus versus continuous infusion (DOSE trial; NEJM March 3, 2011).
- Nitrates: Particularly useful if the patient has concomitant chest pain or is hypertensive.
  1. Nitroglycerin: 0.4 to 0.8 mg SL or nitroglycerin spray may be given immediately on arrival and repeated every 5 min up to three times if the patient remains symptomatic and blood pressure remains stable.
  2. 2% nitroglycerin ointment: 1 to 3 inches out of the tube applied continuously; absorption may be erratic.
  3. IV nitroglycerin for refractory chest pain or and hypertension: Start at 0.2 to 0.4 mcg/kg/min.
- Nitroprusside is useful for afterload reduction in severe hypertension, acute mitral regurgitation, or acute aortic regurgitation.
  1. Start at low-dose 0.5 μg/kg/min with an arterial line in place.
  2. Monitor for cyanide toxicity.
- ACE inhibitors, angiotensin II receptor blockers, aldosterone antagonist, and sacubitril-valsartan are vasodilators with long-term mortality benefit in patients with heart failure with reduced ejection fraction.
- Ultrafiltration/aquapheresis if diuretic resistant.

Pharmacologic-vasopressors:

- Patients with profound hypotension benefit from vasopressors.
  1. Norepinephrine: It is a powerful vasoconstrictor with small inotropic effect.

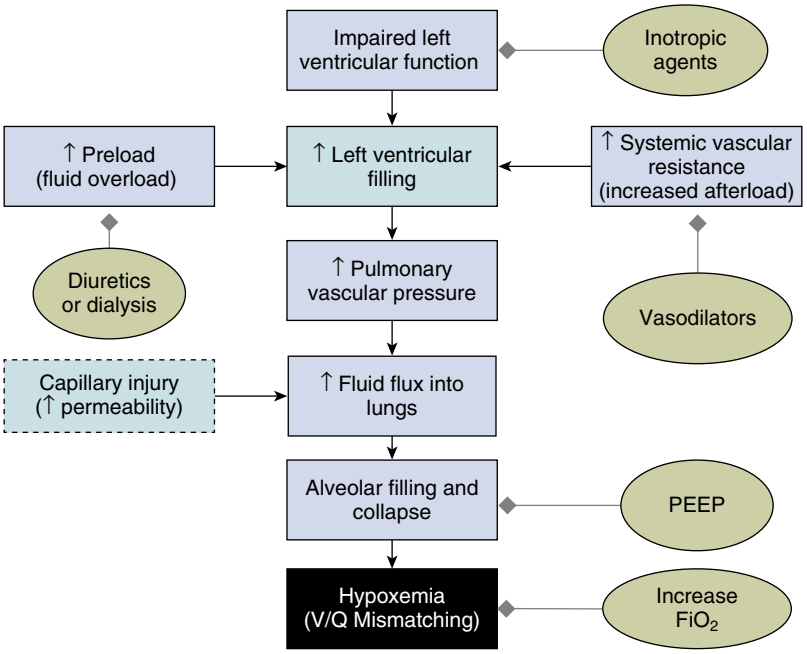

FIG. 3 Acute management of pulmonary edema. This schematic represents basic mechanisms distinguishing cardiogenic and noncardiogenic pulmonary edema and the contributing factors *(blue boxes)* that ultimately lead to impaired gas exchange *(black box)*. The *green circles* represent treatments that are available in the intensive care unit setting to reduce pulmonary edema or to mitigate its adverse consequences. *FiO2*, Fraction of inspired oxygen; *PEEP*, post end-expiratory pressure; *V/Q,* ventilation/perfusion. (From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.)

2. Dopamine: Low doses (0.5 to 3 μg/kg/min) increase blood flow to coronary, renal, and cerebral beds. Intermediate doses (3 to 10 μg/kg/min) increase cardiac contractility while high doses (10 to 20 μg/kg/min) have a pressor effect.

Pharmacologic-inotropes:

- Dobutamine: Potent inotrope, mild chronotropic effects. Dose ranges from 2.5 to 20 mcg/kg/min.
- Phosphodiesterase inhibitors (amrinone, milrinone, and enoximone [not available in U.S.]) may be useful in refractory cases. Milrinone may be associated with increased hypotension and new atrial arrhythmias with increased mortality in patients with ischemia.

Mechanical support:

- Intraaortic balloon pump (IABP): Decreases afterload, increases coronary blood flow.
- Impella: Axial-flow pump on a pigtail catheter that crosses the aortic valve and unloads the left ventricle.
- Tandem heart device: Oxygenated blood is pumped from the left atrium into the femoral artery. It can provide 3.5 to 4.5 L/min of cardiac output.
- Extracorporeal membrane oxygenation (ECMO) as a bridge to heart transplant.
- Durable mechanical circulatory support are advanced therapies that can be considered for those in cardiogenic shock refractory to medical therapy.

DISPOSITION

Admit to ICU/CCU if:

- Need for intubation
- Signs and symptoms of hypoperfusion
- SpO_2 <90% despite supplemental oxygen
- Use of accessory muscles/RR >25/min
- Heart rate <40 or >130, SBP <90

PEARLS & CONSIDERATIONS

COMMENTS

Accumulated evidence still favors the use of noninvasive ventilation, especially CPAP, in patients with ACPE, especially as this therapy reduces dyspnea and helps correct metabolic abnormalities more rapidly than standard oxygen therapy. The role of morphine in the treatment of ACPE has come into question.

BASIC INFORMATION

DEFINITION

Pulmonary embolism (PE) refers to the lodging of a thrombus or other embolic material from a distant site in the pulmonary circulation. A classification of acute pulmonary embolism is described in Table 1.

SYNONYMS

Pulmonary thromboembolism
PE

ICD-10CM CODES

I26	Pulmonary embolism
I26.01	Septic pulmonary embolism with acute cor pulmonale
126.09	Other pulmonary embolism with acute cor pulmonale
126.90	Septic pulmonary embolism without acute cor pulmonale
126.99	Other pulmonary embolism without acute cor pulmonale
127.82	Chronic pulmonary embolism
Z86.711	Personal history of pulmonary embolism

EPIDEMIOLOGY & DEMOGRAPHICS

- 650,000 cases of PE occur in the U.S. each yr (increased incidence in women and with advanced age); annually, as many as 100,000 people in the U.S. die from acute PE, and the diagnosis is often not made until after autopsy. The incidence of PE is increasing with the increasing use of spiral CT scans, with a lower severity of illness and lower mortality, suggesting the increase is caused by earlier diagnosis.
- More than 90% of pulmonary emboli originate in the deep venous system of the lower extremities.
- Pulmonary thromboembolism is associated with >200,000 hospitalizations. 8% to 10% of victims of PE die within the first hour.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most common symptom: Dyspnea (82% to 85%)
- Tachypnea (30% to 60%)
- Cough (30% to 40%)
- Wheezing (20%)
- Chest pain: May be nonpleuritic or pleuritic (infarction) (40% to 49%)
- Syncope (massive PE) (10% to 14%)
- Fever, diaphoresis, apprehension
- Hemoptysis (2%)
- Evidence of DVT may be present (e.g., swelling and tenderness of extremities)
- Cardiac examination may reveal: Tachycardia (23%), increased pulmonic component of S2, murmur of tricuspid insufficiency, right ventricular heave, right-sided S3
- Pulmonary examination: May demonstrate rales, localized wheezing, friction rub

ETIOLOGY

- Thrombus, fat, or other foreign material
- Risk factors for PE:
  1. Prolonged immobilization, reduced mobility
  2. Postoperative state, major surgery
  3. Trauma to lower extremities, immobilizer, or cast
  4. Estrogen-containing birth control pills, hormone replacement therapy
  5. Prior history of DVT or PE
  6. CHF
  7. Pregnancy and early puerperium
  8. Visceral cancer (lung, pancreas, alimentary and genitourinary tracts)
  9. Spinal cord injury
  10. Advanced age
  11. Obesity
  12. Hematologic disease (e.g., factor V Leiden mutation, antithrombin III deficiency, protein C deficiency, protein S deficiency, lupus anticoagulant, polycythemia vera, dysfibrinogenemia, paroxysmal nocturnal hemoglobinuria, acquired protein C resistance without factor V Leiden, G20210A prothrombin mutation)
  13. COPD, diabetes mellitus, acute medical illness
  14. Prolonged air travel
  15. Central venous catheterization
  16. Autoimmune diseases (SLE, IBD, RA)

TABLE 1 Classification of Acute Pulmonary Embolism

Category (Frequency)	Presentation	Therapy
Massive PE (5%-10%)	Systolic blood pressure <90 mm Hg or poor tissue perfusion or multisystem organ failure plus extensive thrombosis, such as "saddle" PE or right or left main pulmonary artery thrombus	Anticoagulation (usually with high-dose intravenous UFH), plus advanced therapy: Systemic thrombolysis, pharmacomechanical catheter–directed therapy, surgical embolectomy, and/or inferior vena cava (IVC) filter.
Submassive PE, high risk (15%)	Hemodynamically stable but moderate or severe RV dysfunction or enlargement, coupled with biomarker elevation indicative of RV microinfarction and/or RV pressure overload	Anticoagulation until decision made regarding implementation of advanced therapy; controversy centers on this group. For systemic thrombolysis, reducing the rate of cardiovascular collapse and death must be balanced against the increased rate of hemorrhagic stroke.
Submassive PE, low risk (5%-10%)	Hemodynamically stable with RV dysfunction or biomarker elevation, but not both	Anticoagulation followed by "watch and wait." Implement advanced therapy if there is clinical deterioration.
Small to moderate PE (70%)	Normal hemodynamics and normal RV size and function	Anticoagulation and consider brief hospital stay or entirely home therapy.

PE, Pulmonary embolism; *RV*, right ventricular; *UFH*, unfractionated heparin.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Myocardial infarction
- Pericarditis
- Pneumonia
- Pneumothorax
- Chest wall pain
- GI abnormalities (e.g., peptic ulcer, esophageal rupture, gastritis)
- CHF
- Pleuritis
- Anxiety disorder with hyperventilation
- Pericardial tamponade
- Dissection of aorta
- Asthma

WORKUP

- Recent guidelines from the Clinical Guidelines Committee of the American College of Physicians for the Evaluation of Patients with Suspected Acute Pulmonary Embolism recommend the following:[1]
  1. Use of validated clinical prediction rules to estimate pretest probability in patients in whom acute PG is being considered.
  2. Not obtaining a D-dimer measurement or imaging studies in patients with low pretest probability of PE and who meet all pulmonary embolism rule-out criteria.
  3. Obtaining a high-sensitivity D-dimer measurement as the initial diagnostic test in patients who have an intermediate pretest probability of PE or in patients with low pretest probability of PE who do not meet all pulmonary embolism rule-out criteria. Clinicians should not use imaging studies as the initial test in patients who have a low or intermediate pretest probability of PE.
  4. Use age-adjusted D-dimer thresholds (age × 10 ng/ml rather than a generic 500 ng/ml) in patients older than 50 yr to determine whether imaging is warranted.
  5. Clinicians should not obtain any imaging studies in patients with a D-dimer level below the age-adjusted cutoff.

TABLE 2 Wells Score for Pulmonary Embolism*

Characteristic	Points
Risk Factors	
Previous pulmonary embolism or deep venous thrombosis	1.5
Immobilization or surgery in the previous 4 wk	1.5
Cancer	1
Clinical Findings	
Hemoptysis	1
Heart rate >100/min	1.5
Clinical signs of deep venous thrombosis	3
Other	
Alternative diagnosis is less likely than pulmonary embolism	3

Interpretation of total score: 0-1 point, low probability; 2-6 points, moderate probability; 7 or more points, high probability.

*Wells PS et al: Derivation of a simple clinical model to categorize patients probability of pulmonary embolism: increasing the models utility with the SimpliRED d-dimer, *Thromb Haemost* 83:416-420, 2000.

TABLE 3 Revised Geneva Score for Pulmonary Embolism*

Characteristic	Points
Risk Factors	
Age >65 yr	1
Previous pulmonary embolism or deep venous thrombosis	3
Surgery (under general anesthesia) or fracture (of lower limbs) within 1 mo	2
Cancer (active or considered cured <1 yr)	2
Clinical Findings	
Unilateral leg pain	3
Hemoptysis	2
Heart Rate	
75-94 beats/min	3
≥95 beats/min	5
Pain on palpation of lower-limb deep veins and unilateral edema	4

Interpretation of total score: 0-3 points, low probability; 4-10 points, moderate probability; ≥11 points, high probability.

*Le Gal G et al: Prediction of pulmonary embolism in the emergency department: the revised Geneva score, *Ann Intern Med* 144:165-171, 2006.

From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.

6. CTPA should be obtained in patients with high pretest probability of PE. Ventilation-perfusion scans should be reserved for patients who have a contraindication to CTPA or if CTPA is not available.
7. A D-dimer measurement should not be obtained in patients with a high pretest probability of PE.

- Clinical assessment alone is insufficient to diagnose or rule out PE. It is also important to remember that no single noninvasive test has both high sensitivity and high specificity for PE. Consequently, in addition to clinical assessment, most patients require an imaging test to diagnose PE. An integrated diagnostic approach to PE is illustrated in Fig. 1.

The Wells prediction rules (Table 2) and the revised Geneva score (Table 3) can be used to estimate the probability of PE. In the Wells prediction rules, each of the following findings is assigned a score:

1. Clinical signs/symptoms of deep vein thrombosis (score = 3.0).
2. No alternate diagnosis as likely or more likely than PE (score = 3.0).
3. Heart rate >100/min (score = 1.5).
4. Immobilization or surgery in last 4 wk (score = 1.5).
5. Previous history of DVT or PE (score = 1.5).
6. Hemoptysis (score = 1.0).
7. Cancer actively treated within last 6 mo (score = 1.0).

- The probability of PE is high if total score is >6, moderate if 2 to 6; and low if <2.
- The modified Wells score divides PE as likely (>4 points) or unlikely (<4 points).
- A low clinical probability of PE in association with a normal plasma D-dimer measurement essentially rules out PE, and further imaging is not needed. If clinical probability is intermediate or high, and/or the D-dimer measurement is abnormal, further workup with imaging is needed.
- The YEARS algorithm is a risk-adjusted D-dimer tool to rule out DVT that allows a threshold of 1000 ng/ml in patients without signs of DVT, no hemoptysis, and in whom PE is considered not to be the most likely diagnosis.
- CT pulmonary angiography (CTPA) (Fig. 2) is an excellent diagnostic modality (83% sensitivity and 96% specificity).
- V/Q scan is reserved for patients with clinically significant contrast allergies or renal insufficiency, or when CTPA is not available.
- Pulmonary angiogram (gold standard) can confirm the diagnosis in equivocal cases, but is rarely used.
- Serial compressive duplex ultrasonography of lower extremities can be used in patients with "low-probability" lung scan and high clinical suspicion (see "Imaging Studies"). It is useful if positive; negative results do not exclude PE.

LABORATORY TESTS

- ABGs may reveal hypoxemia and respiratory alkalosis (decreased Pa_{O_2} and Pa_{CO_2} and increased pH); normal results do not rule out PE.
- Alveolar-arteriolar (A-a) oxygen gradient, a measure of the difference in oxygen concentration between alveoli and arterial blood, may be elevated. However, a normal A-a gradient does not rule out PE.
- High-sensitivity plasma D-dimer measurement: D-dimer assays by ELISA detect the presence of plasmin-mediated degradation products of fibrin that contain cross-linked D fragments in the whole blood or plasma. A normal plasma D-dimer level is useful to exclude PE in patients with a low pretest probability of PE. However, it cannot be used to "rule in" the diagnosis because it increases with many other disorders (e.g., metastatic cancer, trauma, sepsis, postoperative state). Plasma D-dimer can also be used in conjunction with lower-extremity compression ultrasonography in patients with

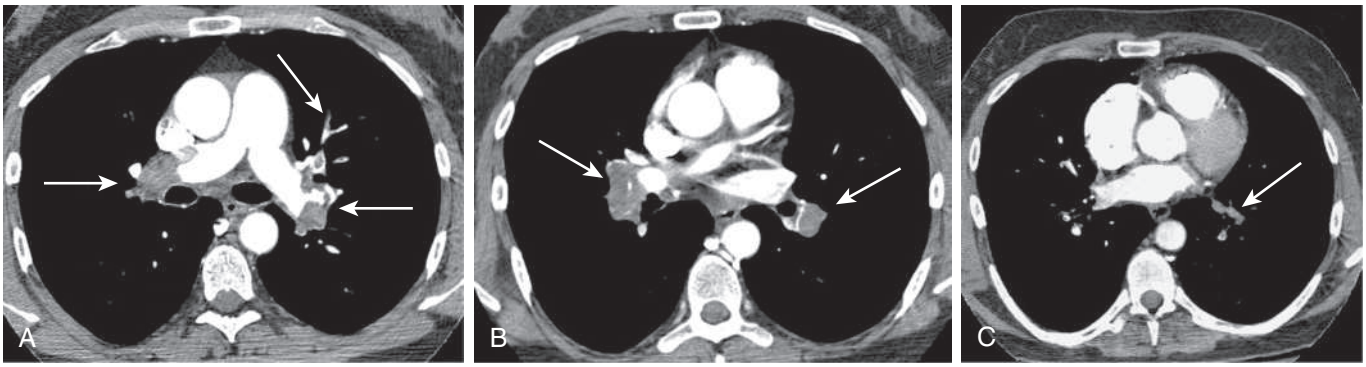

FIG. 2 A 46-yr-old woman presented with acute shortness of breath and hypoxia. Chest radiograph was normal. A, Chest computed tomography shows a low-attenuation filling defect in left and right main pulmonary arteries *(arrows)* and left upper lobe segmental artery *(arrow),* representing massive pulmonary embolism. Emboli extend to left and right interlobar arteries (*arrows),* as well as a left lower lobe segmental artery *(arrow),* seen in **B** and **C,** respectively. (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.)

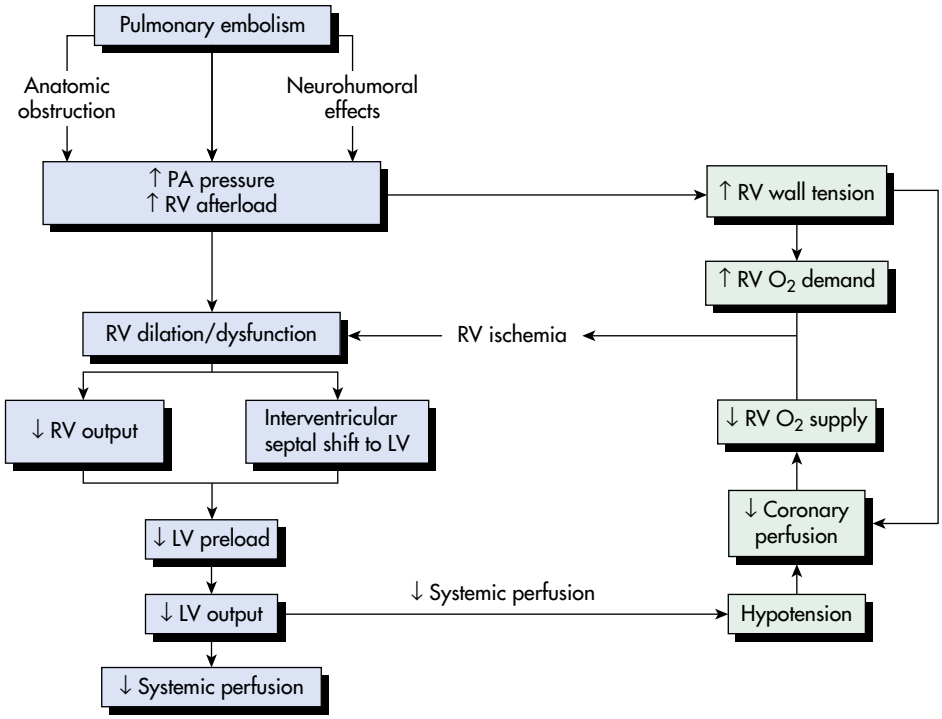

FIG. 3 Pathophysiology of right ventricular dysfunction and its deleterious effects of causing decreased systemic arterial pressure, decreased coronary perfusion, and deteriorating ventricular function. *LV,* Left ventricle/ventricular; *PA,* pulmonary artery; *RV,* right ventricle/ventricular. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

indeterminate V/Q and spiral CT scans. Absence of DVT and presence of a normal D-dimer level in these settings generally rule out clinically significant PE.

- Elevated cardiac troponin levels also occur in patients with PE because of right ventricular dilation and myocardial injury; therefore, PE should be considered in the differential diagnosis of all patients presenting with chest pain or dyspnea and elevated cardiac troponin levels.
- Elevated serum BNP levels in patients with acute PE may reflect RV overload. The pathophysiology of RV dysfunction in PE is illustrated in Fig. 3.
- ECG is abnormal in 85% of patients with acute PE. Frequent abnormalities are sinus tachycardia; nonspecific ST-segment or T-wave changes; S-1, Q-3, T-3 pattern (10% of patients); S-1, S-2, S-3 pattern; T-wave inversion in V_1 to V_6; acute RBBB; new-onset atrial fibrillation; ST segment depression in lead II; right ventricular strain. A right ventricular strain pattern on ECG in patients with PE and normal blood pressure is associated with adverse short-term outcome and adds incremental prognostic value to echocardiographic evidence of right ventricular function.

IMAGING STUDIES

- Chest x-ray may be normal; suggestive findings include elevated diaphragm, pleural effusion, dilation of pulmonary artery, infiltrate or consolidation, abrupt vessel cut-off, oligemia distal to the PE (*Westermark sign*), or atelectasis. A wedge-shaped consolidation in the middle and lower lobes is suggestive of a pulmonary infarction and is known as *Hampton hump.*
- CT angiography is an accurate, noninvasive tool in the diagnosis of PE at the main, lobar, and segmental pulmonary artery levels. A major advantage of CT angiography over standard pulmonary angiography is its ability to diagnose intrathoracic disease other than

PE that may account for the patient's clinical picture. It is also less invasive, less costly, and more widely available. Its major shortcoming is its poor sensitivity for subsegmental emboli.

- V/Q Lung scan (in patient with normal chest x-ray examination): This test must be interpreted within the pretest probability of having a PE.
  1. A normal lung scan rules out PE.
  2. A ventilation-perfusion mismatch is suggestive of PE, and a lung scan interpretation of high probability is confirmatory (Fig. E4).
  3. If the clinical suspicion of PE is high and the lung scan is interpreted as low probability, moderate probability, or indeterminate, a pulmonary arteriogram is diagnostic; a positive arteriogram confirms diagnosis; a positive compressive duplex ultrasonography for DVT obviates the need for an arteriogram, because treatment with IV anticoagulants is indicated in these patients; the overall sensitivity of compressive ultrasonography for DVT in patients with PE is 29%, specificity 97%; adding ultrasonography in patients with a nondiagnostic lung scan prevents 9% of angiographies; however, this improvement in efficacy is achieved at the cost of unnecessary anticoagulant therapy in 26% of patients who have false-positive ultrasonography results.
- Angiography: Pulmonary angiography is the historic gold standard; however, it is invasive, expensive, and not readily available in some clinical settings. False-positive pulmonary angiograms may result from mediastinal disorders such as radiation fibrosis and tumors.
- Gadolinium-enhanced magnetic resonance angiography (MRA/MRV) of the pulmonary arteries has a moderate sensitivity and high specificity for the diagnosis of PE at experienced centers, but obtaining acceptable images is technically challenging and should only be performed if other imaging tests are contraindicated.
- Echocardiography: Useful for identifying patients with PE who may have poor prognosis. Moderate or severe hypokinesis, persistent pulmonary hypertension, patent foramen ovale, and free-floating right heart thrombus are markers for increased risk of death or recurrent thrombosis. Such patients should be considered for thrombolysis or embolectomy.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Correction of risk factors (see "Etiology") to prevent future PE.

ACUTE GENERAL Rx

Patients with acute PE should be initially stratified according to risk so that higher-risk therapies (e.g., thrombolysis, embolectomy) are offered to patients with the greatest chance of benefit.

- Anticoagulants are recommended as initial therapy in patients with small to moderate PE.
- Oral rivaroxaban, a factor Xa inhibitor (15 mg bid for 3 wk, then 20 mg/d), has been studied as a treatment for DVT and for PE, without prior parenteral therapy. For both DVT and PE, treatment with rivaroxaban alone was noninferior to treatment with LMWH followed by a vitamin K antagonist with regard to the endpoint of recurrent venous thromboembolism. Use of rivaroxaban should be avoided in patients with severe renal failure.
- Apixaban, a Factor Xa inhibitor (10 mg twice a day for a week, followed by 5 mg twice a day), is also approved for the treatment of acute PE based on the data in the AMPLIFY and AMPLIFY-EXT trials, in which apixaban met its noninferiority mark in terms of efficacy and improved safety compared to warfarin.
- Unfractionated heparin (UFH) (IV or subcutaneous), subcutaneous low-molecular-weight heparin (LMWH), or subcutaneous fondaparinux can be used for the initial treatment for at least 5 days when used with warfarin or dabigatran. If IV unfractionated heparin is used, a bolus dose (80 U/kg) followed by a weight-based (18 U/kg/hr) continuous infusion to achieve therapeutic anti-factor Xa (or aPTT) levels should be used. LMWH and fondaparinux should be avoided in patients with severe renal failure.
- Thrombolytic agents (urokinase, tPA, streptokinase): Provide rapid resolution of clots with increased risk of major bleeding (up to 3% incidence of intracranial hemorrhage); thrombolytic agents are the treatment of choice in patients with massive PE who are hemodynamically unstable and with no contraindication to their use. Fig. 5 describes treatment of submassive pulmonary embolism. Fig. 6 illustrates the approach to "high-risk" submassive pulmonary embolus with right ventricular injury. The use of thrombolytic agent in the treatment of hemodynamically stable

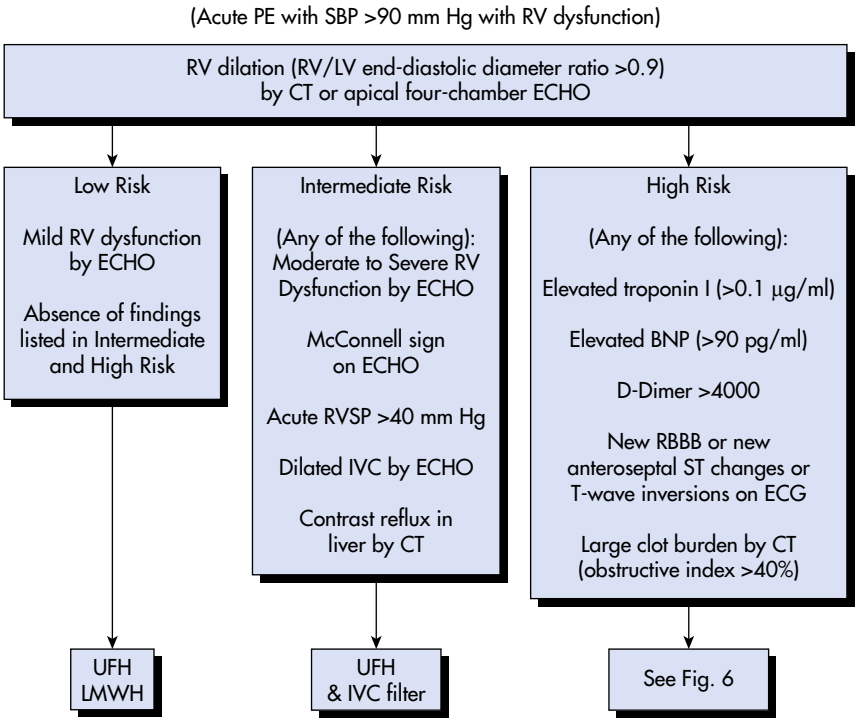

FIG. 5 Submassive pulmonary embolus algorithm. *BNP,* Brain natriuretic peptide; *CT,* computed tomography; *ECG,* electrocardiogram; *ECHO,* echocardiogram; *IVC,* inferior vena cava; *LMWH,* low-molecular-weight heparin; *PE,* pulmonary embolism; *RBBB,* right bundle branch block; *RV,* right ventricle; *RV/LV,* right ventricle/left ventricle; *RVSP,* right ventricular systolic pressure; *SBP,* systolic blood pressure; *UFH,* unfractionated heparin. patients with acute submassive PE remains controversial, although there is some evidence that half-dose tPA has some efficacy. Use of the thrombolytic agents alteplase (100 mg IV over 2-hr period) in normotensive patients with moderate or severe right ventricular dysfunction identified by ECG has been advocated by some physicians. Use of alteplase in conjunction with heparin has been shown to improve the clinical course of stable patients who have acute submassive PE without internal bleeding, mainly by reducing need for subsequent thrombolytic use. Additional studies are needed to confirm these findings before recommending routine use of this therapeutic approach. The Pulmonary Embolism Thrombolysis (PEITHO) trial revealed that in patients with intermediate risk of pulmonary embolism, fibrinolytic therapy prevented hemodynamic compensation but increased the risk of major hemorrhage and stroke.

- Long-term treatment for PE not associated with malignancy can be carried out with warfarin therapy or rivaroxaban.
- For PE associated with malignancy, LMWH is recommended for long-term therapy.
- For PE occurring in the setting of a reversible risk factor, anticoagulation should be continued for 3 mo. For patients with an unprovoked PE, longer-term anticoagulation should be considered, and indefinite long-term anticoagulation should be used in patients with recurrent unprovoked PE. Important factors to consider in the decision to extend anticoagulation include the patient's risk of bleeding and patient preferences after an informed discussion of risks and benefits.
- If thrombolytics and anticoagulants are contraindicated (e.g., GI bleeding, recent CNS surgery, recent trauma) or if the patient continues to have recurrent PE despite anticoagulation therapy, vena caval interruption is indicated by transvenous placement of an inferior vena caval filter.
- In older adults, IVC filters are associated with higher 30-day and 1-yr mortality (11.6% and 20.5%, respectively, versus 9.3% and 13.4% in those who do not); however, these patients tend to be sicker than those who are not.
- Acute pulmonary artery surgical embolectomy or catheter-based thrombectomy may be indicated in a patient with massive PE who cannot receive thrombolytic therapy. Pulmonary embolectomy is also recommended for those whose critical status does not allow sufficient time for thrombolytic therapy to be effective and for those who remain unstable after receiving fibrinolysis.

CHRONIC Rx

- Elimination of risk factors (see "Etiology").
- Patients with unprovoked DVT/PE have a high rate of recurrent VTE. Longer durations of chronic anticoagulation after unprovoked DVT/PE result in lower rates of recurrent DVT/PE while on anticoagulation, but benefits are lost once anticoagulation is halted. The use of indefinite anticoagulation in selected individuals with apparently unprovoked DVT/PE must be weighed against ongoing bleeding risk and other factors.
- Aspirin (100 mg daily) is superior to placebo in preventing recurrence of venous thromboembolism in patients with a first-ever unprovoked venous thromboembolism (VTE) who had already completed 6 to 18 mo of oral anticoagulation. This suggests that aspirin could be offered as an alternative to oral anticoagulants for prevention of recurrent VTE in patients who refuse to or cannot continue oral anticoagulant therapy but who have a high risk of recurrent VTE.
- Trials involving extending the treatment time of the novel oral anticoagulants (rivaroxaban, dabigatran, and apixaban) all showed superior

TABLE 4 Stratification of Risk of Death Associated with Pulmonary Embolism and Severity-Adjusted Treatment*

Early Risk of Death	Risk Factor: Shock or Hypotension (on Clinical Examination)	Risk Factor: Right Ventricular Dysfunction (on Echocardiography or Multidetector CT)	Risk Factor: Myocardial Injury (on Cardiac Troponin Testing)	Recommended Treatment
High	Present	Present†	NA‡	Unfractionated heparin plus thrombolysis or embolectomy
Intermediate§	Absent	Present	Present	Low-molecular-weight heparin or fondaparinux; as a rule, no early thrombolysis; monitor clinical status and right ventricular function
Low	Absent	Absent	Absent	Low-molecular-weight heparin or fondaparinux; consider outpatient treatment

CT, Computed tomography; *RV,* right ventricle.
*Adapted with modifications from the 2008 Guidelines on the Diagnosis and Management of Acute Pulmonary Embolism of the European Society of Cardiology. NA denotes not applicable.
†If RV function is normal on echocardiography, or if a CT scan shows no RV dilation in a patient with hemodynamic compromise and clinically suspected pulmonary embolism, an alternative diagnosis should be sought.
‡Troponin test results do not influence risk assessment or treatment in hemodynamically compromised patients with acute pulmonary embolism.
§Although it has been suggested that normotensive patients with both RV dysfunction and myocardial injury have a higher risk of death than those with only one of these risk factors, there is currently no definitive proof that they should receive more aggressive treatment.
From Konstantinides S: Acute pulmonary embolism, *N Engl J Med* 359:2804-2813, 2008.

TABLE 5 Original and Simplified Pulmonary Embolism Severity Index (PESI)

Variable	Original PESI	Simplified PESI
Age	Age, in yr	1 (if age >80 yr)
Male sex	+10	—
History of cancer	+30	1
History of heart failure	+10	1 for either or both of these items
History of chronic lung disease	+10	
Pulse >110 beats/min	+20	1
Systolic blood pressure <100 mm Hg	+30	1
Respiratory rate >30 breaths/min	+20	—
Temperature <36 °C	+20	—
Altered mental status	+60	—
Arterial oxyhemoglobin saturation (SaO_2) <90%	+20	1
30-DAY MORTALITY RISK STRATA (BASED ON THE SUM OF POINTS)		
LOW-RISK PESI	**LOW-RISK sPESI**	
Class I: <65 Points	**0 Points**	
(event rate 95% CI, 0-1.6)	(event rate 95% CI, 0-2.1)	
Class II: 66-85 Points		
(event rate 95% CI, 1.7-3.5)		
HIGH-RISK PESI	**HIGH-RISK sPESI**	
Class III: 86-105 Points	**≥1 Point**	
(event rate 95% CI, 3.2-7.1)	(event rate 95% CI, 8.5-13.2)	
Class IV: 106-125 Points		
(event rate 95% CI, 4.0-11.4)		
Class V: >125 Points		
(event rate 95% CI, 10.0-24.5)		

CI, Confidence interval; *PESI,* Pulmonary Embolism Severity Index; *sPESI,* Simplified Pulmonary Embolism Severity Index.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

efficacy and reduced morbidity compared to placebo as well as similar rate of major bleeding (though increased all bleeding).

DISPOSITION

- Mortality can be reduced to <10% by rapid and effective treatment. Stratification of risk of death associated with PE and severity-adjusted treatment is described in Table 4. Indicators of poor prognosis include hemodynamic instability/hypotension, signs of RV dysfunction, elevated BNP, elevated troponin, thrombus burden, coexisting DVT, and right ventricular thrombus. The Pulmonary Embolism Severity Index (PESI) is summarized in Table 5.
- Mortality from recurrent pulmonary emboli is 8% with effective treatment and >30% in patients with untreated pulmonary emboli.

PEARLS & CONSIDERATIONS

COMMENTS

- Use of clinical prediction rules in association with D-dimer testing may reduce the use of unnecessary imaging in patients in whom PE is unlikely. A combination of a low clinical pretest probability and a D-dimer level less than 1000 mg per milliliter can identify patients at low risk for pulmonary embolism.[3]
- Massive PE (PE associated with hypotension, shock, or circulatory arrest) remains the clearest situation in which thrombolytics should be employed. Submassive PE (PE associated with right ventricular dysfunction or injury but without hypotension) remains an area of controversy with regard to thrombolytic use.
- A recent prospective study revealed that suspected pulmonary embolism in pregnant patients can be ruled out by using a pregnancy-adapted YEARS diagnostic algorithm across all trimesters of pregnancy. The three following criteria from the YEARS algorithm were used: (1) Clinical signs of deep-vein thrombosis, (2) hemoptysis, (3) pulmonary embolism as the most likely diagnosis. A D-dimer level was also obtained. PE was ruled out if none of the three criteria were met and the D-dimer level was <1000 mg/ml or if one or more of the three criteria were met and the D-dimer level was <500 mg/ml.[2]

BASIC INFORMATION

DEFINITION

Pulmonary hypertension (PH) is defined as the presence of an elevated mean pulmonary arterial pressure (PAP) ≥20 mm Hg at rest (previously ≥25 mm Hg). Pulmonary hypertension is classified into five major groups: pulmonary arterial hypertension (Group 1), pulmonary hypertension due to left heart disease (Group 2), pulmonary hypertension due to lung disease (Group 3), pulmonary hypertension due to chronic thromboembolic disease (Group 4), and miscellaneous (Group 5).

Pulmonary arterial hypertension (PAH) is a syndrome defined as mean pulmonary pressure ≥20 mm Hg with pulmonary capillary wedge pressure <15 mm Hg and a pulmonary vascular resistance ≥3 Wood units on right heart catheterization. Idiopathic pulmonary arterial hypertension (IPAH) is diagnosed when PAH is present without any apparent cause. It is a highly morbid disease characterized by progressive obliteration of precapillary arterioles. This topic will mostly focus on pulmonary arterial hypertension.

SYNONYMS

PH
Pulmonary arterial hypertension
Idiopathic pulmonary arterial hypertension
IPAH
Associated pulmonary arterial hypertension
PAHA, also known as secondary pulmonary hypertension
Heritable pulmonary arterial hypertension
HPAH
Group I pulmonary hypertension

ICD-10CM CODES
I27.0 Primary pulmonary hypertension
I27.2 Other secondary pulmonary hypertension

EPIDEMIOLOGY & DEMOGRAPHICS

- IPAH is rare, occurring in one to two cases per 1 million people per yr, with an overall prevalence estimated at 15 to 50 per 1 million.
- IPAH is more common in women than men (3:1), usually presenting in the third to fourth decades of life.
- In adults the most common cause of pulmonary hypertension is due to left-sided heart disease (Group 2).
- Prevalence of secondary PAH could range from 8% to 12% in cases of scleroderma, 0.5% of HIV, 23% to 53% of mixed connective tissue disorders, and 1% to 4% cases of systemic lupus erythematosus.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Insidious, may go undetected for yrs
- Exertional dyspnea most common presenting symptom (60%)
- Fatigue and weakness
- Anorexia/abdominal pain
- Syncope, classically exertion-related or after a warm shower with peripheral vasodilation
- Chest pain
- Hoarse voice from compression of recurrent laryngeal nerve by an enlarged pulmonary artery (Ortner syndrome)
- Hemoptysis
- Rarely, palpitations due to atrial fibrillation or atrial flutter
- Loud P2 component of the second heart sound and paradoxical splitting of second heart sound
- Right-sided S4
- Jugular venous distention
- Abdominal distention and ascites
- Prominent parasternal (right ventricular [RV]) impulse
- Holosystolic tricuspid regurgitation murmur heard best along the left fourth parasternal line that increases in intensity with inspiration
- Peripheral edema
- Features of the physical exam pertinent to the evaluation of pulmonary hypertension are summarized in Table 1

ETIOLOGY

- The etiology of IPAH is unknown.
- APAH (associated PAH) has several known risk factors: connective tissue disorders such as systemic sclerosis, portal hypertension and liver cirrhosis, appetite-suppressant drugs (e.g., fenfluramine), and infections, including schistosomiasis and HIV disease. High altitude, schistosomiasis, and HIV disease are common causes of PH worldwide; however, pulmonary venous hypertension from left ventricular failure and PH related to COPD are more common causes of PH in developed nations.
- Several genetic abnormalities have been associated with HPAH (heritable PAH), many of which are mutations in the genes that code for members of the tumor growth factor-beta family of receptors (BMPR-II, ALK-1, endoglin) on chromosome 2q33.
- Up to 25% of patients with IPAH have abnormal BMPR-II structure or function, while up to 80% of hereditary PAH is due to mutations in BMPR-II.
- Mutations in *KCNK3, SMAD9,* and *CAV1* have also been associated with both familial and idiopathic pulmonary arterial hypertension.
- Heritable PAH is an autosomal-dominant disease with variable penetrance, affecting only about 10% to 20% of carriers.
- Several factors play a role in the pathogenesis of PAH, including a genetic predisposition, endothelial cell dysfunction, abnormalities in vasomotor control, thrombotic obliteration of the vascular lumen, and vascular remodeling through cell proliferation and matrix production.
- SSRI use in late pregnancy is associated with increased persistent PAH in newborns.
- The updated clinical classification of pulmonary hypertension is described in Table 2.

DIAGNOSIS

- PAH is a hemodynamic diagnosis involving the detection of elevated pressure in the pulmonary arteries and elevated pulmonary vascular resistance in the pulmonary vascular bed, occurring in the absence of significant pulmonary venous hypertension.
- Right-sided heart catheterization must be performed in all patients suspected of having PAH to establish the diagnosis and to assess pulmonary hemodynamics including reactivity response to vasodilators.
- One of the most challenging differential diagnoses of IPAH is heart failure with preserved EF (HFpEF). In such patients, the PCWP may be at the higher limit of normal at rest. Exercise or fluid challenge at the time of right heart catheterization can result in disproportionate rise in PCWP, which favors group 2 pulmonary hypertension.
- IPAH is a diagnosis of exclusion; causes that lead to groups 2 to 5 pulmonary hypertension must be ruled out. TTE, HR-CT, PFT, and V/Q scan must be performed before the diagnosis of IPAH is established and treatment started.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is as listed under "Etiology." Table 3 summarizes distinguishing pulmonary arterial hypertension from heart failure with preserved ejection fraction.

EVALUATION

- Consists of establishing the diagnosis and etiology.
- Echocardiography with Doppler technique can provide a noninvasive but limited estimation of systolic PAP. Common findings include tricuspid regurgitation, right heart enlargement, abnormal movement of septum and, rarely, pericardial effusion. However, the diagnosis of PH cannot be established by echocardiography alone, as echocardiography can overestimate or underestimate PAP.
- ECG shows RV enlargement, strain pattern, and right axis deviation.
- Chest radiograph (Fig. 1) shows enlarged central pulmonary arteries and right heart enlargement. Chest radiography is abnormal in 90% of patients at diagnosis.
- A normal chest radiograph does not rule out the diagnosis. High-resolution computed tomography (CT) (Fig. E2) can assist in the evaluation for emphysema or interstitial lung disease. Ventilation-perfusion lung scan has high sensitivity for chronic thromboembolic disease. CT angiography is less sensitive for diagnosing chronic thromboembolic disease. The diagnosis can be confirmed by pulmonary angiography, which has high specificity. Pulmonary angiography is also useful in identifying patients who can benefit from pulmonary endarterectomy (PEA).
- Cardiac magnetic resonance imaging (CMR) can provide accurate noninvasive evaluation of the right ventricular size, morphology, and function.

TABLE 1 Features of the Physical Examination Pertinent to the Evaluation of Pulmonary Hypertension

Sign	Implication
PHYSICAL SIGNS THAT REFLECT THE SEVERITY OF PULMONARY HYPERTENSION	
Accentuated pulmonary component of S_2 (audible at the apex in >90%)	High pulmonary pressure that increases force of pulmonic valve closure
Early systolic click	Sudden interruption of opening of the pulmonary valve into a high-pressure artery
Midsystolic ejection murmur	Turbulent transvalvular pulmonary outflow
Left parasternal lift	High right ventricular pressure and hypertrophy present
Right ventricular S4 (in 38%)	High right ventricular pressure and hypertrophy present
Increased jugular A wave	Poor right ventricular compliance
PHYSICAL SIGNS THAT SUGGEST MODERATE TO SEVERE PULMONARY HYPERTENSION	
Moderate to severe pulmonary hypertension	
Holosystolic murmur that increases with inspiration	Tricuspid regurgitation
Increased jugular V waves	
Pulsatile liver	
Diastolic murmur	Pulmonary regurgitation
Hepatojugular reflux	High central venous pressure
Advanced pulmonary hypertension with right ventricular failure	
Right ventricular S3 (in 23%)	Right ventricular dysfunction
Distention of jugular veins	Right ventricular dysfunction or tricuspid regurgitation, or both
Hepatomegaly	Right ventricular dysfunction or tricuspid regurgitation, or both
Peripheral edema (in 32%)	
Ascites	
Low blood pressure, diminished pulse pressure, cool extremities	Reduced cardiac output, peripheral vasoconstriction
PHYSICAL SIGNS THAT SUGGEST A POSSIBLE UNDERLYING CAUSE FOR OR ASSOCIATIONS WITH PULMONARY HYPERTENSION	
Central cyanosis	Abnormal ventilation-perfusion ratio, intrapulmonary shunt, hypoxemia, pulmonary-to-systemic shunt
Clubbing	Congenital heart disease, pulmonary venopathy
Cardiac auscultatory findings, including systolic murmurs, diastolic murmurs, opening snap, and gallop	Congenital or acquired heart or valvular disease
Rales, dullness, or decreased breath sounds	Pulmonary congestion or effusion, or both
Fine rales, accessory muscle use, wheezing, protracted expiration, productive cough	Pulmonary parenchymal disease
Obesity, kyphoscoliosis, enlarged tonsils	Possible substrate for disordered ventilation
Sclerodactyly, arthritis, telangiectasia, Raynaud phenomenon, rash	Connective tissue disorder
Peripheral venous insufficiency or obstruction	Possible venous thrombosis
Venous stasis ulcers	Possible sickle cell disease
Pulmonary vascular bruits	Chronic thromboembolic pulmonary hypertension
Splenomegaly, spider angiomas, palmar erythema, icterus, caput medusae, ascites	Portal hypertension

From McLaughlin VV et al: ACCF/AHA 2009 expert consensus document on pulmonary hypertension: a report of the American College of Cardiology Foundation Task Force on Expert Consensus Documents and the American Heart Association developed in collaboration with the American College of Chest Physicians; American Thoracic Society, Inc., and the Pulmonary Hypertension Association, *J Am Coll Cardiol* 53:1573, 2009; In Mann DL et al: *Braunwald's heart disease,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 2 Updated Clinical Classification of Pulmonary Hypertension

1 PAH
- 1.1 Idiopathic PAH
- 1.2 Heritable PAH
- 1.3 Drug- and toxin-induced PAH
- 1.4 PAH associated with:
  - 1.4.1 Connective tissue disease
  - 1.4.2 HIV infection
  - 1.4.3 Portal hypertension
  - 1.4.4 Congenital heart disease
  - 1.4.5 Schistosomiasis
- 1.5 PAH long-term responders to calcium channel blockers
- 1.6 PAH with overt features of venous/capillaries (PVOD/PCH) involvement
- 1.7 Persistent PH of the newborn syndrome

2 PH due to left heart disease
- 2.1 PH due to heart failure with preserved LVEF
- 2.2 PH due to heart failure with reduced LVEF
- 2.3 Valvular heart disease
- 2.4 Congenital/acquired cardiovascular conditions leading to postcapillary PH

3 PH due to lung disease and/or hypoxia
- 3.1 Obstructive lung disease
- 3.2 Restrictive lung disease
- 3.3 Other lung disease with mixed restrictive/obstructive pattern
- 3.4 Hypoxia without lung disease
- 3.5 Developmental lung disorders

4 PH due to pulmonary artery obstructions
- 4.1 Chronic thromboembolic PH
- 4.2 Other pulmonary artery obstructions

5 PH with unclear and/or multifactorial mechanisms
- 5.1 Hematologic disorders
- 5.2 Systemic and metabolic disorders
- 5.3 Others
- 5.4 Complex congenital heart disease

TABLE 3 Distinguishing Pulmonary Arterial Hypertension (PAH) from Heart Failure with Preserved Ejection Fraction (HFpEF)

Characteristic	PAH More Likely	HFpEF More Likely
Age	Younger	Older
Comorbid conditions—DM, HTN, CAD, obesity (metabolic syndrome)	Often absent	Often multiple present
Symptoms—PND, orthopnea	Often absent	Often present
Cardiac examination	RV heave, loud P_2, TR murmur	Sustained LV impulse, LS4
CXR	Clear lung fields	Pulmonary vascular congestion, pleural effusions, pulmonary edema
Chest CT	Often clear lungs	Mosaic perfusion pattern, ground-glass opacities consistent with chronic interstitial edema
ECG	RAD, RVE	LAE, LVE, atrial fibrillation, no RAD
Natriuretic peptides	Often elevated	Often elevated
Echo—LAE, LVH	Absent	Often present
Echo—diastolic dysfunction	Grade 1 common	Grade 2, 3 common
Echo—right ventricle	Often enlarged, may share the apex	Often normal, mildly enlarged
Echo—pericardial effusion	Sometimes	Rare

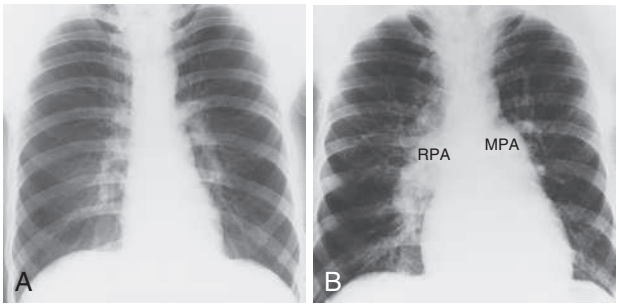

FIG. 1 Progressive pulmonary arterial hypertension. This patient initially presented with a relatively normal chest radiograph **(A).** However, several yrs later **(B)** there is increasing heart size and marked dilation of the main pulmonary artery *(MPA)* and right pulmonary artery *(RPA).* Rapid tapering of the arteries as they proceed peripherally is suggestive of pulmonary hypertension and is sometimes referred to as pruning. (From Mettler FA [ed]: *Primary care radiology,* Philadelphia, 2000, WB Saunders.)

- Pulmonary function tests may show obstructive (airway disease) and/or restrictive disease (parenchymal disease) depending on etiology. Diffusion capacity of carbon monoxide in the lung is reduced due to pulmonary vascular destruction in PAH.
- In asymptomatic patients the severity of pulmonary arterial hypertension (PAH) disease should be evaluated in a systematic and consistent manner, using a combination of World Health Organization (WHO) functional class (FC), exercise capacity, and echocardiographic, laboratory, and hemodynamic variables to inform therapeutic decisions.
- Right heart catheterization is required to assess pulmonary hemodynamics, exclude shunts and left heart disease, and perform acute vasoreactivity response testing.
- Symptomatic patients with PAH, in the absence of contraindications, should undergo acute vasoreactivity testing using a short-acting agent at a center with experience in the performance and interpretation of vasoreactivity testing.
- Screening for the presence of PAH with Doppler echocardiography is warranted in individuals with a known predisposing genetic mutation or first-degree relative with IPAH, connective tissue diseases (especially scleroderma), congenital heart disease with left-to-right shunt, HIV, sickle cell disease, or portal hypertension undergoing evaluation for orthotopic liver transplantation.
- Determining the degree of functional impairment, as assessed by the WHO functional classification system (Classes I-IV) and the 6-min walk test (6MWT), is a useful way to monitor disease progression and assess response to treatment.
- The longitudinal evaluation of patients with pulmonary arterial hypertension is summarized in Table 4.

LABORATORY AND DIAGNOSTIC TESTS

- Complete blood count is usually normal in PAH but may show secondary polycythemia.
- Arterial blood gases show low PO_2 and oxygen saturation.
- Overnight oximetry and/or sleep study to rule out sleep apnea or hypopnea.
- Other blood tests: Antinuclear antibody (ANA), antineutrophil cytoplasmic antibodies (ANCA), anti-Scl-70, anticentromere, antitopoisomerase, anti-Ro, anti-La, anti-RNA polymerase III, ribonucleoprotein antibody levels, and rheumatoid factor (RF) to screen for underlying connective tissue disease, HIV serology, liver function tests, and antiphospholipid antibodies.
- Brain natriuretic peptide (BNP) level can provide prognostic information, with elevation in BNP level being associated with increased mortality.
- Ventilation-perfusion lung scan has high sensitivity for chronic thromboembolic PAH. The diagnosis should be confirmed by pulmonary angiography, which has high specificity.

Rx TREATMENT (FIG. 3)

- Most of the evidence in management of PAH is limited to IPAH/HPAH. There is some evidence in treatment of APAH associated with connective tissue disease, especially scleroderma, and congenital heart disease. The recommendations for treating PAH associated with other causes are limited to case studies and expert opinions.
- There is some evidence for the use of advanced therapies for sarcoidosis-associated PH. The heterogeneity of sarcoid-associated PH complicates the interpretation.

GENERAL MEASURES AND TREATMENT:

- Patients should be encouraged to remain active within symptom limits and avoid excessive physical activity.
- Exercise training appears to be beneficial for patients with PH. It is associated with improved exercise capacity, muscular function, quality of life, and possibly right ventricular function and pulmonary hemodynamics.
- PAH is a contraindication to pregnancy as it carries a 30% to 50% mortality risk.
- PAH patients have a higher risk of death from infections and should receive age-appropriate vaccines as well as be vaccinated against influenza and pneumococcal pneumonia.
- Although there are no randomized data to suggest that long-term O_2 therapy is beneficial, oxygen administration has shown to

TABLE 4 Longitudinal Evaluation of Patients with Pulmonary Arterial Hypertension*

	Low Risk	High Risk
Clinical course	Stable; no increase in symptoms and/or decompensation	Unstable; increase in symptoms and/or decompensation
Physical examination	No evidence of right-sided heart failure	Signs of right-sided heart failure
Functional class†	I/II	IV
6MW distance†	>400 m	<300 m
Echocardiogram	RV size/function normal	RV enlargement/dysfunction
Hemodynamics	RAP normal CI normal	RAP high CI low
BNP	Nearly normal/remaining stable or decreasing	Elevated/increasing
Treatment	Oral therapy	Intravenous prostacyclin and/or combination treatment
Frequency of evaluation	Every 3-6 mo‡	Every 1-3 mo
FC assessment	Every clinic visit	Every clinic visit
6MW distance	Every clinic visit	Every clinic visit
Echocardiogram§	Yearly or center dependent	Every 6-12 mo or center dependent
BNP¶	Center dependent	Center dependent
RHC	Clinical deterioration and center dependent	Every 6-12 mo or clinical deterioration

BNP, Brain natriuretic peptide; *CI,* cardiac index; *FC,* functional class; *IV,* intravenous; *RAP,* right atrial pressure; *RV,* right ventricle; *6MW,* 6-min walk.

*For patients in the high-risk category, consider referral to a PAH specialty center for consideration of advanced therapies, clinical trials, and/or lung transplantation.

†The frequency of follow-up evaluation for patients in functional class III and/or 6MW distance between 300 and 400 m would depend on a composite of detailed assessments of the other clinical and objective characteristics listed.

‡For patients who remain stable with established therapy, follow-up assessments can be performed by referring physicians or PH specialty centers.

§Echocardiographic measurement of pulmonary artery systolic pressure is an estimation only, and it is strongly advised that its evaluation not be relied on as the sole parameter to make therapeutic decisions.

¶The usefulness of serial BNP levels to guide management in individual patients has not been established.

From McLaughlin VV et al: ACCF/AHA 2009 expert consensus document on pulmonary hypertension. A report of the American College of Cardiology Foundation Task Force on Expert Consensus Documents and the American Heart Association developed in collaboration with the American College of Chest Physicians; American Thoracic Society, Inc.; and the Pulmonary Hypertension Association, *J Am Coll Cardiol* 53:1573, 2009.

From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

reduce PVR. Ambulatory O_2 may be considered for exercise-induced desaturations to maintain oxygen saturations of >90%.

- Diuretics (e.g., furosemide 40 to 80 mg qd) improve dyspnea by reducing preload and peripheral edema. Avoid excessive diuresis in patients who are preload dependent.
- Digoxin has been used in patients with IPAH with inconclusive benefits. It can be considered in patients who develop atrial tachyarrhythmia. There is no conclusive data regarding the use of beta-blockers, ACE inhibitors, or ARB in IPAH unless required by comorbidities such as concurrent hypertension or cardiomyopathy.
- Evidence for the use of oral anticoagulation with warfarin for IPAH is derived mostly from retrospective single-center experience. Data from RCT and registries remain heterogenous and inconclusive. A large multicenter observational longitudinal registry of patients with IPAH (REVEAL Registry) assessed the effect of warfarin treatment on survival and found no benefit; it also found poorer survival in patients with PAH associated with systemic sclerosis. Generally, patients with IPAH who are undergoing IV prostaglandin therapy are anticoagulated if there are no contraindications to anticoagulation, as they are at high risk for catheter-related thrombosis. There are no data regarding the role of novel oral anticoagulants in IPAH.
- Iron deficiency with or without anemia is common and is associated with reduced exercise capacity; it should be closely monitored and replenished as needed.

CHRONIC Rx

Calcium channel blocker (CCB):

- Acute vasoreactivity response testing should be done in all patients at the time of right heart catheterization. Epoprostenol, adenosine, or nitric oxide is generally used to assess the response. A positive response is a fall in mean PAP of ≥10 mm Hg to a value of <40 mm Hg, with increased or unchanged cardiac output. Fewer than 10% of patients are responders in IPAH, and they are the only patients who can be safely treated with this type of therapy. Acute vasoreactivity study is not recommended for patients in groups 2 to 5.
- The positive responders may benefit from treatment with calcium channel blockers (diltiazem, amlodipine, or nifedipine). All patients should be reassessed in 6 to 8 wk to demonstrate sustained benefit from the calcium channel blocker.
- CCBs should not be used empirically to treat PAH in the absence of demonstrated acute vasoreactivity because of potential severe side effects.
- If patients do not show an adequate response, additional PAH therapy should be started.

PROSTANOIDS

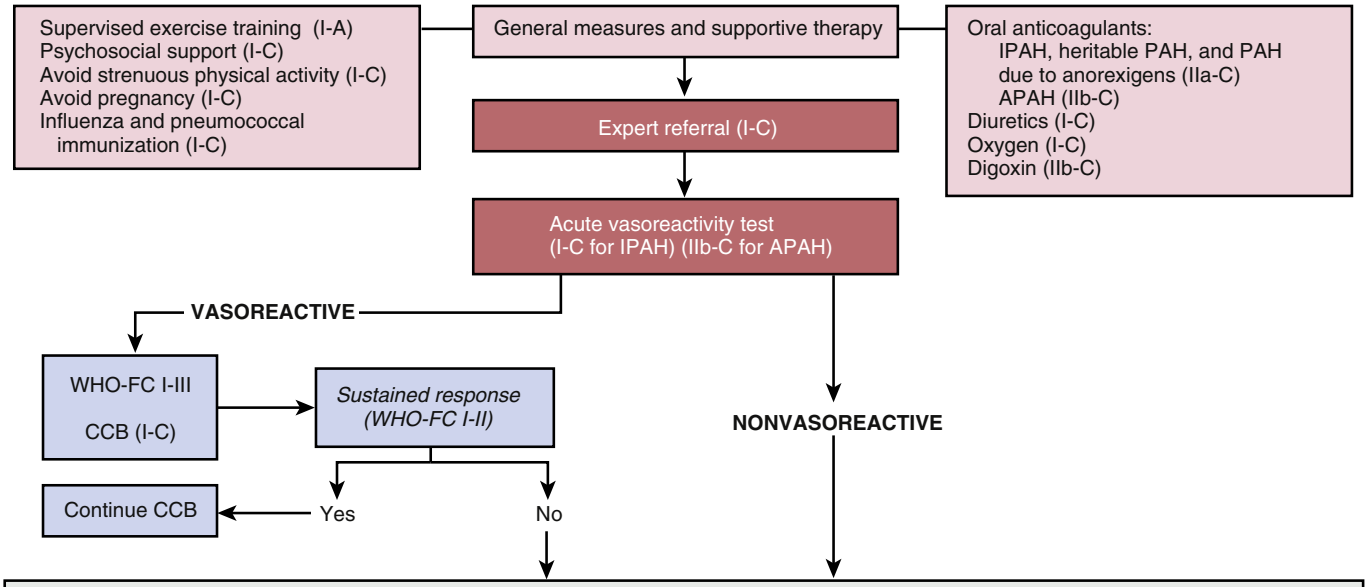
- These synthetic prostacyclin analogues act as potent vasodilators of pulmonary arteries and inhibitors of platelet aggregation. They all have shown improvement in symptoms, exercise capacity including 6MWD, and hemodynamics. They are ideal for WHO functional class III and IV patients.
  1. Epoprostenol: IV formulation with very short half-life (3 to 5 min). It is the most studied drug, and it is the only one that has shown to improve mortality. It requires long-term IV access with associated risks of infection and thrombosis. Rapid tachyphylaxis with dose escalation is seen. Common side effects include flushing, headache, jaw pain, abdominal cramping, and diarrhea. Limited evidence exists for use in secondary PAH patients.
  2. Treprostinil: IV and SQ formulation with longer half-life. Main disadvantage is pain at SQ pump site (no long-term evidence for IV formulation). Treprostinil is also available as a nebulized inhaled solution.
  3. Iloprost: Aerosolized formulation with short half-life requiring 6 to 8 treatments/day. Oral and IV forms are also available. Well tolerated, with flushing and jaw pain being the most frequent side effects.
  4. Beraprost: PO formulation. Not approved in the U.S.

RIOCIGUAT: GUANYLATE CYCLASE STIMULATORS

Guanylate cyclase stimulators enhance cGMP production and in preclinical studies show antiproliferative and antiremodeling properties in animal models. These oral agents are useful for class II and III patients and have shown favorable results on exercise capacity, hemodynamics (decrease in PVR), WHO functional class, and time to clinical worsening without any mortality benefit. There has also been reported benefit in patients with inoperable and persistent chronic group IV pulmonary hypertension with improvement in 6MWD and reduction in PVR. The most serious side effect is syncope.

Endothelin receptor antagonists (ERAs):

Activation of the endothelin system results in vasoconstriction of the pulmonary vascular smooth muscles. Most of these oral pulmonary vasodilators require monthly liver function tests, and often the response is delayed by wks. Thus it is not an ideal starting therapy for WHO class IV patients. It is effective in class II and III patients and improves symptoms, exercise capacity, and hemodynamics without any improvement in mortality.



INITIAL THERAPY WITH PAH-APPROVED DRUGS

RED: Morbidity and mortality as primary endpoint in randomized controlled study or reduction in all-cause mortality (prospectively defined)

* Level of evidence is based on the WHO-FC of most of the patients in the studies

† Approved only, in the United States (treprostinil inhaled), in New Zealand (iloprost IV), in Japan and S. Korea (beraprost)

‡ Drugs under regulatory approval

Recommendation	Evidence*	WHO-FC II	WHO-FC III	WHO-FC IV

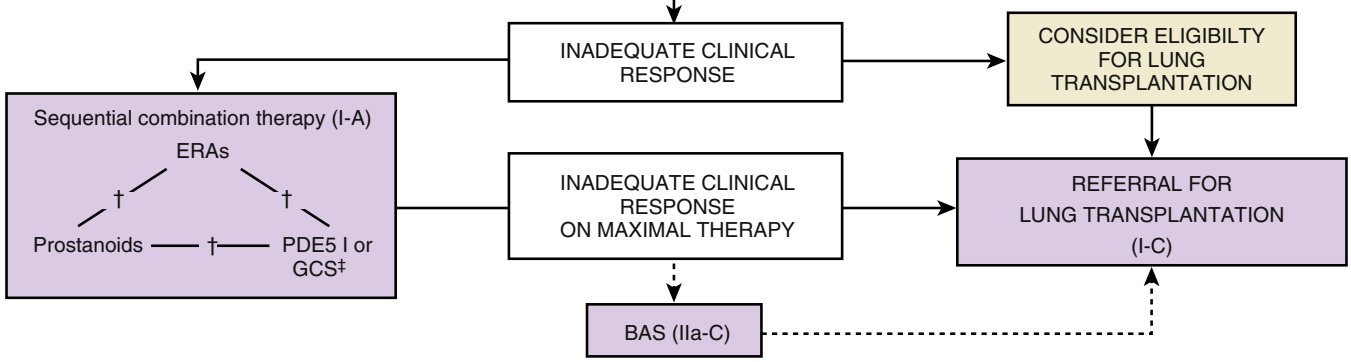

FIG. 3 Treatment algorithm for pulmonary arterial hypertension *(PAH)*. Background therapies include warfarin anticoagulation, which is recommended in all patients with IPAH and no contraindication. Diuretics are used for the management of right-sided heart failure. Oxygen is recommended to maintain oxygen saturation higher than 90%. Acute vasodilator testing should be performed in all patients with IPAH who may be potential candidates for long-term therapy with calcium channel–blocking agents (CCBs). Patients with PAH caused by conditions other than IPAH have a very low rate of long-term responsiveness to oral CCBs, and the value of acute vasodilator testing in such patients needs to be individualized. Patients with IPAH in whom CCB therapy would not be considered, such as those with right-sided heart failure or hemodynamic instability, should not undergo acute vasodilator testing. CCBs are indicated only for patients who have a positive acute vasodilator response, and such patients need to be monitored closely for both safety and efficacy. For patients who did not have positive acute vasodilatory testing and are considered to be at lower risk based on clinical assessment (see Table 5), oral therapy with an endothelin receptor antagonist (ERA) or phosphodiesterase-5 inhibitor (PDE5 I) would be the first line of therapy recommended. If an oral regimen is not appropriate, consideration of the other treatments would need to be based on the patient's profile, side effects, and risk associated with each therapy. For patients who are considered high risk based on clinical assessment (Table 5), continuous treatment with an intravenous prostacyclin (epoprostenol or treprostinil) would be the first line of therapy recommended. If a patient is not a candidate for continuous intravenous treatment, consideration of the other therapies would have to be based on the patient's profile and the side effects and risk associated with each treatment. Epoprostenol improves exercise capacity, hemodynamics, and survival in patients with IPAH and is the preferred treatment option for the most critically ill patients. Combination therapy should be considered when patients are not responding adequately to initial monotherapy. *APAH,* Associated PAH; *BAS,* balloon atrial septostomy; *GCS,* guanylate cyclase stimulators; *IPAH,* idiopathic pulmonary arterial hypertension; *IV,* intravenous; *SC,* subcutaneous; *WHO-FC,* World Health Organization functional class. From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.)

TABLE 5 Pulmonary Arterial Hypertension: Determinants of Prognosis*

Determinants of Risk (estimated 1-yr mortality)	Lower Risk (<5%)	Intermediate Risk (5-10%)	Higher Risk (>10%)
Clinical evidence of RV failure	No	No	Yes
Progression of symptoms	No	Gradual	Rapid
WHO class†	I, II	III	IV
6MW distance‡	>440 m	164-440 m	<165 m
CPET	Peak V_{O_2} >15 ml/kg/min	Peak V_{O_2} 11-15 ml/kg/min	Peak V_{O_2} <11 ml/kg/min
Echocardiography	No pericardial effusion, No RA enlargement, Minimal RV dysfunction	No or minimal pericardial effusion, minimal RA enlargement	Pericardial effusion, significant RV enlargement/dysfunction, right atrial enlargement
Hemodynamics	RAP <8 mm Hg, CI >2.5 L/min/m^2	RAP 8-14mmHg CI 2-2.4 L/min/m2	RAP >14mm Hg, CI <2.0 L/min/m^2
BNP§	Not elevated	Mildly elevated	Significantly elevated

BNP, Brain natriuretic peptide; *CI,* cardiac index; *CPET,* cardiopulmonary exercise testing; *peak* V_{O_2}, average peak oxygen uptake during exercise; *RA,* right artrial; *RAP,* right atrial pressure; *RV,* right ventricular; *WHO,* World Health Organization.

*Most data available pertain to IPAH, with little data available for other forms of PAH. One should not rely on any single factor to make risk predictions.

†The WHO class is the functional classification for PAH and is a modification of the NHYA functional class.

‡6MW distance is also influenced by age, sex, and height.

§Because data regarding the influence of BNP on prognosis are currently limited and many factors, including renal function, weight, age, and sex, may influence BNP, absolute numbers are not given for this variable.

From McLaughlin VV et al: ACCF/AHA 2009 expert consensus document on pulmonary hypertension. A report of the American College of Cardiology Foundation Task Force on Expert Consensus Documents and the American Heart Association developed in collaboration with the American College of Chest Physicians; American Thoracic Society, Inc.; and the Pulmonary Hypertension Association, *J Am Coll Cardiol* 53:1573, 2009. In Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

- Bosentan is an oral nonselective endothelin A and B receptor blocker, whereas sitaxsentan and ambrisentan are oral selective endothelin A receptor blockers. Ambrisentan does not require monitoring of liver function tests.
- ERAs have been shown to cause improvement in exercise capacity, WHO functional class, hemodynamic and echocardiographic variables without affecting mortality.
- Macitentan is a nonselective endothelin receptor antagonist that showed significant reduction in composite end point of death in patients with IPAH. It was thought not to cause liver toxicity, but postmarketing analysis suggested it can cause liver toxicity. It however more frequently can cause anemia and pharyngitis.

Phosphodiesterase (PDE-5) inhibitors:

- These are oral agents that act by inhibiting phosphodiesterase type 5 enzyme (PDE-5), resulting in increased concentration of nitric oxide causing vasodilation through the cGMP/NO pathway. In addition, they exert antiproliferative effects. Highly effective in WHO class II patients, both in IPAH and scleroderma-associated PAH. Improve symptoms, exercise capacity including 6MWD, hemodynamics, and time to clinical worsening. Mortality benefit was not studied. Most side effects are related to vasodilion including headache, flushing, and epistaxis.
- Sildenafil is administered as 20 mg PO tid. Tadalafil dose is 40 mg once daily. They are also used as combination therapy with epoprostenol and endothelin receptor antagonists.

Prostacyclin agonists:

Selexipag is an oral selective nonprostanoid prostacyclin IP receptor agonist approved for PAH. The IP receptor promotes vasodilation and antiproliferation. Selexipag has been shown to decrease disease progression and hospitalizations without any effect on mortality. Side effects are mild and consist of headache, jaw pain, flushing, and diarrhea.

Treatment considerations depending on WHO functional class:

- According to consensus definition, patients with PAH who demonstrate acute vasoreactivity should be considered candidates for therapy with an oral CCB, except in the case of right heart failure or other contraindications.
- CCBs should not be used empirically to treat PAH in the absence of demonstrated acute vasoreactivity, as described previously.
- For treatment-naïve PAH patients with WHO functional class (FC) II or III symptoms who are not candidates for, or who have failed, CCB therapy, monotherapy should be initiated with an approved ERA, phosphodiesterase-5 (PDE5) inhibitor, or the soluble guanylate cyclase stimulator riociguat.

- For treatment-naïve PAH patients with WHO FC IV, prostanoids are first line.
- For treatment-naïve PAH patients with WHO FC III symptoms who have evidence of rapid progression of their disease or other markers of a poor clinical prognosis, consideration of initial treatment with a parenteral prostanoid is recommended.
- For treatment-naïve PAH patients in WHO FC IV who are unable, or do not desire, to manage parenteral prostanoid therapy, treatment with an inhaled prostanoid in combination with an ERA is recommended.
- For WHO FC III or IV PAH patients with unacceptable clinical status despite established PAH-specific monotherapy, addition of a second class of PAH therapy to improve exercise capacity is recommended. Such patients should be evaluated at centers with expertise in the evaluation and treatment of complex patients with PAH.
- Combination therapies: Considered when there is no improvement or deterioration on monotherapy. The FDA has approved the use of ambrisentan and tadalafil together as the first two-drug regimen for PAH because it is associated with a significant reduction in the rate of clinical failure compared with monotherapy with either drug alone (AMBITION trial). Starting dose is 5 mg for ambrisentan and 20 mg for tadalafil once daily.
- Bosentan + inhaled iloprost (STEP trial) showed some benefit over monotherapy.
- IV epoprostenol + oral bosentan (BREATH-2 trial) did not show a statistically significant difference when compared with monotherapy.
- IV epoprostenol + oral sildenafil (PACES trial) showed benefit over monotherapy.

INVASIVE Rx

- Lung transplantation and heart-lung transplantation are other options in patients with end-stage class IV disease.
- Atrial septostomy may be performed as a bridge to transplant. It involves creation of an interatrial communication, resulting in right-to-left shunt, which decreases right-sided pressure and increases LV preload and cardiac output. Atrial septostomy is recommended for individuals with a room air SaO_2 >90% who have severe right-sided heart failure (with refractory ascites) despite maximal diuretic therapy, or who have signs of impaired systemic blood flow (such as syncope) from reduced left heart filling.
- Extracorporeal membrane oxygenation (ECMO) is also commonly used as a bridge to transplant.
- Patients should be referred for lung transplant if:
  1. They have WHO FC III or IV during escalating treatment
  2. They have rapidly progressive disease
  3. Parenteral therapy is utilized
  4. Pulmonary venoocclusive disease (PVOD) or pulmonary capillary hemangiomatosis is known or suspected

Lung transplant recipients with IPAH have survival rates of 52% to 75% at 5 yr and 45% to 66% at 10 yr.

TREATMENT OF SECONDARY PAH, APAH:

- Directed toward cause. Some situations merit mention:
  1. PAH with uncorrected congenital heart disease: Eisenmenger syndrome. Medical treatment generally ineffective. Heart-lung transplantation required in most patients. PH may persist after surgical correction of congenital heart disease, and pulmonary vasodilators can be effective therapies in this patient population.
  2. PAH with scleroderma: Selective pulmonary vasodilators are effective.
  3. PAH with lung disease or hypoxia: Oxygen therapy for hypoxemia, CPAP for OSA, control of primary disease process.
  4. PAH with chronic thromboembolic disease: Pulmonary endarterectomy is curative; may consider pulmonary vasodilators, notably riociguat, after anticoagulation (for at least 3 mo and if endarterectomy is not an option) if continued symptoms and elevation in PVR and transpulmonary gradient.
  5. PAH with HIV: Control of viral load by antiretroviral therapy.

DISPOSITION

- The 6MWT is predictive of survival in patients with idiopathic PAH. A baseline 6MWT <250 m is associated with a 50% risk of death at 2 yr. Drop in O_2 saturation >10% during the test increases mortality risk 2.9 times over a median follow-up of 26 mo.
- Cardiopulmonary exercise testing (CPET) is also performed, during which gaseous exchange and ventilation are continuously measured during incremental exercise. A peak oxygen uptake (pVO_2) of <10 ml/kg/min independently predicts a worse prognosis.
- A BNP level ≥350 pg/ml at baseline evaluation is associated with a 25% risk of death at 2 yr.
- WHO class II and III patients with PAH have a mean survival of 3.5 yr.
- WHO class IV patients have a mean survival of 6 mo.
- As per the REVEAL (Registry to Evaluate Early and Long-term Pulmonary Arterial Hypertension Disease Management) risk score, poor prognostic signs include:
  1. Signs of RV failure
  2. WHO functional class III or IV
  3. Walk a distance of <165 meters in 6-min walk test
  4. Peak VO2 <10 ml/min/kg in cardiopulmonary testing
  5. Elevated BNP levels >180 pg/ml
  6. Presence of pericardial effusion
  7. TAPSE [tricuspid annular plane systolic excursion] <2 cm on echo of right ventricle
  8. Right atrial pressure >20 mm Hg or pulmonary vascular resistance of >32 Wood units on right heart catheterization
  9. Increased heart rate >92 or BP <109 mm Hg
  10. Male gender >60 yr of age
  11. Concomitant renal dysfunction with estimated glomerular filtration rate ≤30/ml/min/m
  12. Diffusion capacity of lung for carbon monoxide (DLCO) <33%

REFERRAL

If the diagnosis of IPAH/HPAH is suspected, a consultation with a pulmonary specialist is recommended. PHA may require disease-specific consultations. Advanced cases need to be transferred to transplant centers.

PEARLS & CONSIDERATIONS

- The exertional dyspnea of PAH is typically described by patients as being relentlessly progressive over several mos to a yr, often out of proportion to, or in the absence of, underlying heart or lung disease.
- Over 20% of patients in the Registry to Evaluate Early and Long-term PAH Disease Management had symptoms for more than 2 yr before PAH was recognized. Consideration of the diagnosis of PAH in the differential diagnosis of unexplained dyspnea, especially in younger individuals, is essential.
- Chest x-ray may reveal evidence of interstitial fluid or fibrosis within the lungs in cases of secondary PH. IPAH is not associated with infiltrates on chest radiograph.

COMMENTS

- RV systolic pressure (RVSP) as estimated by echocardiography is not a good indicator of the presence of PAH because RVSP increases with age and body mass index. Athletically conditioned men also have a higher resting RVSP. Thus these measurements can be misleading.
- Abrupt development of pulmonary edema during acute vasodilator testing suggests pulmonary venoocclusive disease or pulmonary capillary hemangiomatosis and is a contraindication to long-term vasodilator treatment.
- In advanced PAH, heart rate increase is the main compensatory mechanism and reflects increased sympathetic tone. A higher heart rate at rest is an important marker of prognosis and should be assessed at frequent intervals after initiation of treatment for PAH.

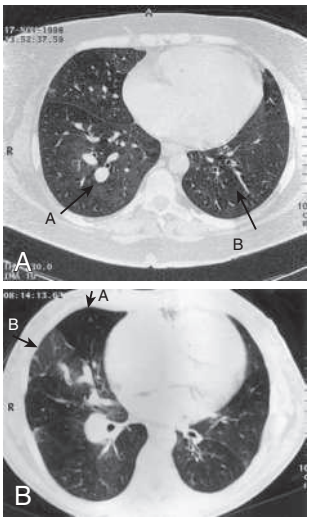

FIG. E2 Chest computed tomographic scans in a patient with chronic thromboembolic pulmonary hypertension. A, Helical scan with contrast medium enhancement of the pulmonary vasculature shows a marked disparity in vessel size between the involved vessels *(A),* which are enlarged from thrombus, and the uninvolved vessels *(B).* **B,** Non–contrast-enhanced high-resolution scan illustrates a marked mosaic pattern manifest by differences in density of regions of the lung parenchyma reflecting the perfused areas *(B)* and the nonperfused areas *(A),* also consistent with underlying thromboembolic disease. (From Zipes DP et al [eds]: *Braunwald's heart disease,* ed 7, Philadelphia, 2005, WB Saunders.)

BASIC INFORMATION

DEFINITION

Pulseless electrical activity (PEA) is defined as the presence of organized cardiac electrical activity without sufficient mechanical contraction to produce a palpable pulse.

SYNONYM

Electromechanical dissociation (EMD)

ICD-10CM CODES

I46.9	Cardiac arrest, cause unspecified
I49.9	Cardiac arrhythmia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Accounts for about 35% of cardiac arrest cases
- Increasingly recognized as the cause of sudden cardiac death in patients with implantable cardioverter-defibrillators

PHYSICAL FINDINGS & CLINICAL PRESENTATION

PRIMARY PEA:

- Organized electrical activity (not VT/VF)
- No detectable pulse

SECONDARY PEA: As in primary PEA and may also have:

- Bradycardia: Drug overdose, elevated vagal tone
- Tachycardia: Hypovolemia, massive PE
- Elevated JVP and no pulse with CPR: Cardiac tamponade, massive PE, tension pneumothorax
- Absent unilateral breath sounds and tracheal deviation: Tension pneumothorax
- Cyanosis: Hypoxia

ETIOLOGY

PRIMARY PEA: Myocardial electromechanical uncoupling secondary to advanced heart muscle disease

SECONDARY PEA: Related to changes in the loading conditions of the heart, ischemia, and/or myocardial depressants. Current guidelines suggest using the 5Hs and 5Ts as diagnostic tools when determining the etiology:

- **H**ypovolemia
- **H**ypoxia
- **H**ypothermia
- **H**ypo-/hyperkalemia
- **H**ydrogen ions (acidosis)
- **T**ension pneumothorax
- **T**amponade
- **T**hrombosis in the lungs (pulmonary embolism)
- **T**hrombosis in the heart (ACS)
- **T**oxins: β-blockers, calcium channel blockers, digoxin, tricyclic antidepressants, benzodiazepines, opioids

DIAGNOSIS

WORKUP

- Stabilizing patient and workup to establish etiology should proceed simultaneously
- History, physical examination, laboratory tests, imaging studies (refer to 5Hs/5Ts)

LABORATORY TESTS

- CBC, potassium, magnesium, CK-MB, troponin, toxicology screen
- Arterial blood gas
- ECG (Fig. E1):
  1. Low voltage: Tamponade
  2. Right heart strain (S1-Q3-T3 pattern, right axis deviation): PE, pneumothorax
  3. Arrhythmias: MI, metabolic abnormalities, drug effects
  4. ST changes, Q waves: MI

IMAGING STUDIES

- Chest radiograph: Rule out pneumothorax, aortic dissection (widened mediastinum).
- Echocardiogram: Rule out tamponade, ischemia (LV contractility, wall motion), valve dysfunction, tumors, and clots. May help diagnose aortic dissection and PE and assess intravascular volume status.
- Abdominal radiograph or ultrasound: Rule out ruptured abdominal aortic aneurysm.

TREATMENT

- Identifying and treating a reversible cause is critical.
- Physiologic parameters can help monitor quality of CPR and detect the return of spontaneous circulation (ROSC). Suggested methods include quantitative waveform capnography, arterial relaxation diastolic pressure, arterial pressure monitoring, or central venous oxygen saturation.

NONPHARMACOLOGIC THERAPY

- Activate emergency response service.
- Begin CPR; ensure high quality, minimize interruptions. Perform CPR for 2 min between pauses to assess rhythm and circulation.
- Attach cardiac monitor/defibrillator.
- Obtain IV/intraosseous (IO) access.
- Consider advanced airway placement.
- Confirm absence of blood flow with Doppler ultrasound, arterial line, or bedside echocardiogram.

ACUTE GENERAL Rx

- Treat specific cause if known.
- Give 100% oxygen.
- Epinephrine 1 mg IV push/IO, q3 to 5min.
- Give normal saline (20 ml) bolus after peripheral IV administration of medication to improve its distribution.
- Medication can be given via endotracheal tube if IV/IO access cannot be obtained; IV/IO routes preferred because they provide more predictable drug delivery and pharmacologic effects. Give 2 to 2.5× the IV dose in 10 ml of sterile water.
- If rhythm changes to VF or pulseless VT:
  1. Defibrillate.
  2. For refractory VF or pulseless VT consider amiodarone.
- If achieve ROSC, initiate postcardiac arrest care.

DISPOSITION

Of hospitalized patients who develop PEA, <15% survive to discharge. Survival rates much lower in patients with prehospital PEA. Survivors often have poor neurologic outcomes.

REFERRAL

As needed for underlying condition

PEARLS & CONSIDERATIONS

- The benefit of epinephrine in PEA resuscitation is uncertain; it may be associated with worse neurologic outcomes and increased long-term mortality. However, the 2015 American Heart Association guidelines support its continued use.
- Targeted temperature management (32 °C to 36 °C [89.6 °F to 96.8 °F] for 24 hr) may improve neurologic outcomes and reduce mortality in comatose cardiac arrest survivors; however, the evidence for therapeutic hypothermia in PEA is based on nonrandomized trials and its role continues to be evaluated. The current AHA guidelines published in 2015 recommend therapeutic hypothermia for all cardiac arrest patients without contraindications.
- Termination of resuscitation guidelines exist for out-of-hospital cardiac arrest. Similar guidelines for in-hospital cardiac arrest are not available; termination of resuscitation is based on multiple patient factors.
- Prognostication is more difficult in patients treated with hypothermia and may be guided by testing, but no single exam finding or test is definitive; a multimodal approach is needed. Delay neurologic testing for at least 72 hr after ROSC. In addition to neurologic examination (corneal and pupillary reflexes, motor response), testing may include median nerve somatosensory-evoked potentials, EEG, biomarkers, and neuroimaging. Wait >72 hr after return to normothermia before attempting to predict outcome.

AUTHOR: **Nathan Riddell, MD**

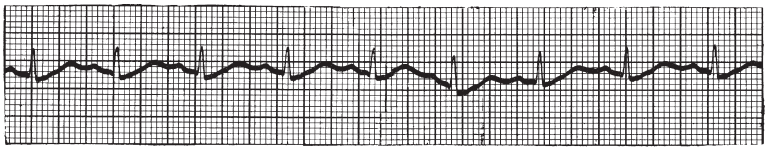

FIG. E1 Sinus rhythm with pulseless electrical activity (PEA). Although the electrocardiogram showed sinus rhythm, the patient had no pulse or blood pressure. In this case the PEA was a result of depressed myocardial function after a cardiac arrest. (From Goldberg AL: *Clinical electrocardiography,* ed 5, St Louis, 1994, Mosby.)

BASIC INFORMATION

DEFINITION

Pure red cell aplasia (PRCA) is characterized by a triad of severe anemia, reticulocytopenia (<1%), and the absence of erythroid precursors in the bone marrow. All other cell lineages (namely, myeloid precursors and megakaryocytes) are normal. Table E1 describes the classification of PRCA.

SYNONYMS

PRCA
Congenital hypoplastic anemia
Joseph-Blackfan-Diamond syndrome
Acquired red cell aplasia

ICD-10CM CODES

D61.01	Constitutional (pure) red blood cell aplasia
D60.0	Chronic acquired pure red cell aplasia

EPIDEMIOLOGY & DEMOGRAPHICS

- The frequency of this disease has been underestimated mainly due to self-limiting nature of most of the cases.
- Rare disease (WHO classification).

PREDOMINANT SEX AND AGE: The male:female ratio is 2:1 for PRCA with thymoma. However, immune-mediated cases are seen more commonly in females.

GENETICS: A mutation in the gene *RPS19* located at 19q13.2 can be seen in 25% of congenital hypoplastic anemia patients.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Anemia is the primary problem in PRCA.
- Patients with severe anemia can present with fatigue, pallor, tachycardia, and dyspnea.
- Congenital hypoplastic anemia is usually associated with physical findings of short stature, abnormal thumbs, and mental retardation.
- Other stigmata of underlying illnesses such as splenomegaly, enlarged parotid glands, lymphadenopathy, leg ulcers, and thymomas may be evident.
- Physical findings related to complications from therapy including iron overload secondary to PRBC transfusions; corticosteroid therapy and immunotherapy may also be present.

ETIOLOGY (TABLE E2)

- Congenital: Usually sporadic caused by injury to stem cells in utero.
- Acquired: The inciting events in the development of PRCA are not known; however, viruses or exposure to chemicals can serve as potential triggers (Fig. E1).
  1. Acute and often self-limited (usually secondary to drugs, chemicals [Table E3], and viral infections)
  2. Chronic and often requiring treatment of the underlying disorder (hematologic and solid malignancies, thymomas, autoimmune disorders, and immunocompromised states)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- PRCA:
  1. Bone marrow findings: Diminished RBC precursors but otherwise normal cellularity
  2. Peripheral blood: Anemia only
  3. Cytogenetics: Usually normal
- Myelodysplastic syndrome:
  1. Bone marrow findings: Hypercellular with dysplasia
  2. Peripheral blood: Cytopenia(s) with cellular dysplasia
  3. Cytogenetics: Abnormal
- Hemolytic anemia:
  1. Bone marrow findings: Normal cellularity, potentially increased erythrocyte precursors
  2. Peripheral blood: Anemia with elevated LDH, bilirubin, and reticulocyte count; decreased haptoglobin, and positive direct antiglobulin (Coombs) test in autoimmune hemolytic anemia
  3. Cytogenetics: Normal
- Aplastic anemia:
  1. Bone marrow findings: Hypocellular
  2. Peripheral blood: Pancytopenia
  3. Cytogenetics: Usually normal

WORKUP

A search should always be made for the underlying condition. Bone marrow examination is required to diagnose PRCA. Fig. E2 is a diagnostic algorithm for PRCA.

LABORATORY TESTS

- CBC with peripheral smear: Normocytic, normochromic anemia
- Reticulocyte count: Diminished (<1% or <10,000/μL)
- No changes in WBC or platelet count unless

TABLE E1 Classification of Pure Red Cell Aplasia

	Congenital (DBA)	
Primary	Autoimmune Idiopathic	
Secondary	Thymoma	CLL
	Hematologic malignancies	T-LGL/chronic NK-LGL leukemia
		Myeloma
		NHL
		MDS
		ALL
	Solid tumors	Renal cell carcinoma
		Thyroid cancer
		Various adenocarcinomas
	Infections	Parvovirus B19
		EBV, mumps
		HIV, HTLV-1
		CMV
		Viral hepatitis (hepatitis A, hepatitis B)
		Leishmaniasis
		Gram-positive systemic infections (e.g., staphylococcemia)

TABLE E2 Causes of Acquired Red Cell Aplasia

Drugs	Viruses
Procainamide	Parvovirus B19
Phenytoin	Mumps
Sulfonamides	Hepatitis
Zidovudine	Infectious mononucleosis (Epstein-Barr virus)
Azathioprine	Atypical *Mycoplasma*
Chloramphenicol	
Isoniazid	
Recombinant erythropoietin therapy/anti-EPO antibodies	
Malignancies	**Autoimmune Conditions**
Thymomas (5%)	Systemic lupus erythematosus
Chronic lymphocytic leukemia, chronic myeloid leukemia	Rheumatoid disease
Hodgkin disease	Autoimmune hemolytic anemia
Large granular lymphocyte leukemia	
Immunocompromised States	**Others**
Human immunodeficiency virus	Pregnancy
Human T-lymphotrophic virus type 1	ABO-incompatible hematopoietic cell transplantation
Idiopathic	

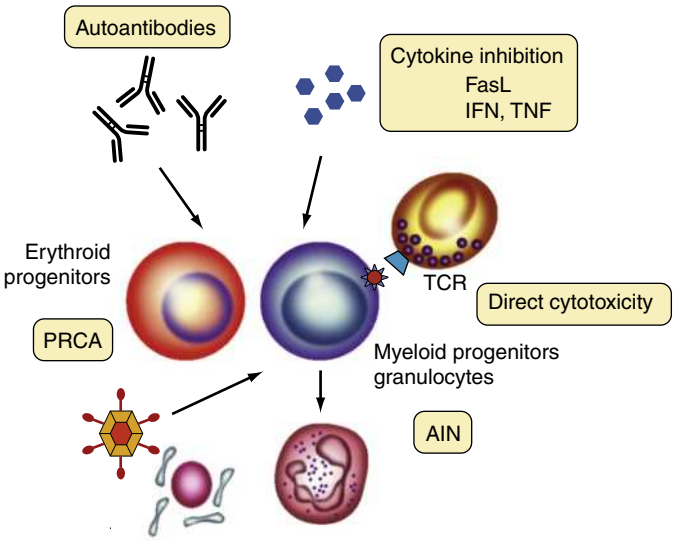

FIG. E1 Pathogenesis of pure red cell aplasia. *AIN,* Autoimmune neutropenia; *FasL,* Fas ligand; *IFN,* interferon; *PRCA,* pure red cell aplasia; *TCR,* T-cell receptor; *TNF,* tumor necrosis factor. (From Hoffman R et al: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2018, Elsevier.)

there is an underlying hematologic disorder (e.g., chronic lymphocytic leukemia, large granular lymphocyte leukemia)
- Bone marrow biopsy is essential to make this diagnosis and rule out other causes: Normocellular marrow with normal myeloid precursors and megakaryocytes but absent erythroid precursors
- Viral titers, if clinically indicated
- Antinuclear antibody testing
- Basic labs including hepatic and renal function tests and haptoglobin, LDH
- Negative direct antiglobulin (Coombs) test
- Chest x-ray or chest CT should be ordered in all cases to rule out underlying thymoma
- Specialized test may include karyotyping and immunophenotyping and peripheral flow cytometry if underlying hematologic disorder is suspected

Rx TREATMENT

NONPHARMACOLOGIC THERAPY
- Treatment of the underlying cause
- Discontinuation of possible offending drugs
- Packed red blood cell (PRBC) transfusion for severely symptomatic anemia
- Immediate hematologic consultation
- Viral infections usually resolve spontaneously in 2 to 3 wk
- About 10% to 15% of patients have thymomas. Surgical resection results in amelioration of anemia in 30% of cases

ACUTE GENERAL Rx
- PRBC transfusion is indicated for symptomatic anemia.
- A vast majority of patients have a protracted remitting and relapsing course, requiring long-term support of anemia with blood transfusions and long-term treatment with immunosuppressive agents.

CHRONIC Rx
- In refractory and relapsed cases, immunosuppressive therapy usually with prednisone as monotherapy or in combination with cyclosporine or cyclophosphamide or antithymocyte globulin (ATG) should be considered.
- Allogeneic hematopoietic stem cell transplantation is considered in the most severe cases refractory to initial immunotherapy.
- Immunocompromised hosts with PRCA secondary to parvovirus infection may not improve spontaneously and often benefit from high-dose intravenous immunoglobulin (IVIG) therapy.
- Certain cases of thymomas with PRCA that do not respond to surgery may respond to somatostatin analogs (e.g., octreotide) in combination with prednisone.
- In patients with pure cell aplasia caused by antierythropoietin antibodies, stopping erythropoietin therapy and transfusing RBCs can help to correct severe anemia.

DISPOSITION
- Acute self-limited PRCA has an excellent prognosis.
- The mortality rate is low in most of the acquired chronic cases but may have significant morbidity related to the underlying condition and complication of therapy.
- Patients with congenital red cell aplasia undergo remission in 15% to 25% of cases and may not need treatment again, or may relapse after reaching adulthood.

REFERRAL
All patients should be referred to a hematologist for complete workup, diagnosis, initiation of appropriate treatments, and monitoring of the response to therapy.

PEARLS & CONSIDERATIONS

COMMENTS
- Rare diagnosis.
- Many cases self-limiting; those associated with malignancies require treatment of the underlying condition.

PREVENTION
Medications implicated as the cause of PRCA should be avoided.

PATIENT & FAMILY EDUCATION
- The consequences of iron overload and secondary hemosiderosis from repeated transfusion therapy should be explained to patients.
- The possibility of the transmission of infections with transfusions and immunotherapy should be discussed with patients.
- Long-term use of corticosteroids, immunomodulators can result in significant adverse effects that should be explained to patients.

BASIC INFORMATION

DEFINITION

Ascending infection of a bacterial pathogen that infects the renal pelvis and kidney. It primarily presents as a urinary tract infection (UTI) characterized by painful urination (dysuria) with associated flank pain/tenderness, nausea, vomiting, and/or fever. The elderly may also present with failure-to-thrive, unexplained anorexia, other organ system decompensation, or generalized deterioration.

CONSISTS OF TWO GROUPS:

- ***Uncomplicated:*** Can be treated as an outpatient with oral antibiotics.
- ***Complicated:*** Inpatient treatment with intravenous antibiotics is required. Hospitalization is indicated for persistent vomiting, progression of uncomplicated UTI, suspected sepsis, immunosuppression, or urinary tract obstruction. This is a potentially life-threatening infection that can lead to renal parenchymal damage. Timely diagnosis and management can significantly impact patient outcomes.

SYNONYMS

Acute pyelonephritis
Pyonephrosis
Renal carbuncle
Lobar nephronia
Acute bacterial nephritis

ICD-10CM CODES

N10	Acute tubulo-interstitial nephritis
N11	Chronic tubulo-interstitial nephritis
N11.0	Nonobstructive reflux-associated chronic pyelonephritis
N11.1	Chronic obstructive pyelonephritis
N11.8	Other chronic tubulo-interstitial nephritis
N11.9	Chronic tubulo-interstitial nephritis, unspecified
N12	Tubulo-interstitial nephritis, not specified as acute or chronic
N20.9	Calculus pyelonephritis

Use additional code (B95-B97) to identify infectious agent.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Pyelonephritis is extremely common in the U.S. (450,000 cases per yr), with the highest incidence in the summer. Pyelonephritis accounts for 9.1% to 31% of severe sepsis cases annually, depending on geographic area. Mortality averages 16.1% annually, ranging from 5% for ages <25 yr to 43% for ages >64 yr.

PREDOMINANT SEX: Women are 5 times more likely to be hospitalized than men until age 65 yr. In males beyond age 65 yr, the difference in prevalence narrows. Risk factors associated with pyelonephritis in healthy women are sexual intercourse (3 or more times weekly over the previous 30 days), a new sex partner in the past yr, use of spermicide, UTI in the past 12 mo, mother with a history of UTI, diabetes mellitus, and urinary incontinence. Urinary tract obstruction is the most important risk factor for a complicated UTI.

PREDOMINANT AGE: Trimodal distribution described in females:

- Girls, ages 0 to 4 yr
- Women, ages 15 to 35 yr especially if sexually active
- Gradual increase in frequency after age 50 yr, with peak incidence at 80 yr

Bimodal distribution in males:

- Boys, ages 0 to 4 yr
- Gradual increase in prevalence after age 35 yr with peak incidence at 85 yr

GENETICS: Congenital urologic structural disorders associated with vesicoureteral reflux predispose to infections at an early age (<5 yr) and produce renal scarring in most males and some females. Pyelonephritis may produce an Ask-Upmark kidney (segmental renal hypoplasia) which is found more often in young females with severe hypertension.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Diagnosis established by clinical presentation, history, and physical examination.

Pyelonephritis is suspected in cases of lower urinary tract symptoms (e.g., urinary frequency, urgency, and dysuria) and frequently accompanied by any of the following:

- Fever, rigors, chills (fever may not be present in the elderly or immunosuppressed)
- Flank pain
- Hematuria: Gross hematuria occurs rarely in acute pyelonephritis and raises suspicion for acute cystitis, papillary necrosis, or lower genitourinary malignancy
- Toxic appearance
- Nausea and vomiting
- Headache
- Diarrhea

Physical examination may elicit costovertebral angle tenderness with exquisite flank pain, a nearly universal finding. Its absence suggests an alternative diagnosis. Patients presenting with nephrolithiasis/ureterolithiasis usually do not present with costovertebral angle tenderness. Usually, abdominal or suprapubic tenderness is present.

ETIOLOGY

Ascending infections from intestinal bacteria that colonize the perineum and vulva in women account for most infections. Less commonly, bacteria, viruses, or fungal pathogens may produce hematogenously induced pyelonephritis.

- Gram-negative bacilli cause 95% of cases (e.g., *E. coli* and *Klebsiella* species).
- Less common gram-negative bacteria may produce infection, particularly after urinary tract instrumentation (e.g., *Enterobacter, Serratia,* and *Proteus mirabilis, Pseudomonas*, among others).
- Resistant gram-negative organisms or fungi such as *Candida* may colonize indwelling catheters.
- Gram-positive organisms such as enterococci and rarely, *Staphylococcus saprophyticus.*
- *Staphylococcus aureus* indicates hematogenous spread to the kidneys.
- Viruses generally are limited to the lower urinary tract.
- Urea-splitting organisms generate alkaline urine, which fosters production of staghorn calculi. These stones may grow to large size and cause infection, obstruction, or both.

In the elderly, *E. coli* is less common (60%). Diabetics develop infections from *Klebsiella* species, Enterobacteriaceae, *Clostridia* species, or *Candida* species.

During the past decade, community-acquired bacteria (particularly *E. coli*) that produce extended-spectrum beta-lactamases have emerged as a cause of acute pyelonephritis worldwide. The most common risk factors for these uropathogens include frequent visits to health care centers, recent use of antimicrobials (e.g., cephalosporins and fluoroquinolones), older age, immunosuppression, recurrent pyelonephritis, nephrolithiasis, and comorbid conditions such as diabetes mellitus and recurrent UTIs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis includes the following:

- Abdominal abscess
- Acute abdomen
- Appendicitis
- Basilar pleural process
- Diverticulitis
- Endometriosis
- Herpes zoster
- Lower rib fracture
- Metastatic disease
- Musculoskeletal disorders
- Nephrolithiasis
- Pancreatitis
- Papillary necrosis
- Pelvic inflammatory disease
- Prostatitis
- Pulmonary infarctions
- Renal corticomedullary necrosis
- Renal vein thrombosis
- Retroperitoneal hemorrhage or abscess
- Splenic abscess or infarct
- Urinary tract obstruction
- Vascular pathology

WORKUP

Evaluation includes prostate health assessment in older males.

URINALYSIS

Conducted on a clean-catch voided or catheterized specimen, if unable to void or cooperate. Dipstick and microscopic examination must be performed on a fresh specimen for preservation of formed elements (e.g., cells, casts, and microorganisms). Most cases demonstrate pyuria and positive leukocyte esterase in association with a positive blood reaction and

microhematuria. Leukocyte casts are generally of renal origin but may be absent.

URINE CULTURE

Historically, clean, midstream cultures are obtained from all patients suspected of having acute pyelonephritis to guide antibiotic therapy. However, a clean-catch specimen may not be necessary because recent evidence demonstrates no significant difference in the number of contaminated or unreliable culture results when collected with or without preparatory cleansing. Obtain a catheterized urine sample if the patient is unable to void, is uncooperative, or has a change in mental status. There is no difference in colony counts or organisms between catheterized and midstream voiding samples.

More than 95% of acute pyelonephritis cases exhibit more than 10^5 colony-forming units of a single bacterium per ml of urine. However, it is important to obtain an accurate history regarding the timing of culture acquisition and prior antibiotic administration. A negative culture with classic clinical and radiological findings does not rule out acute pyelonephritis as proven in a prospective study in which only 23.5% of 196 patients with clinical and radiological evidence of acute pyelonephritis demonstrated positive urine cultures. A urine Gram stain may aid in the choice of empiric antimicrobial therapy pending urine culture. If gram-positive cocci are seen, one should consider *Enterococcus* species or *Staphylococcus saprophyticus* as causative.

Post-treatment urinalysis and culture are unnecessary if symptomatic improvement occurs, but these studies should be obtained if symptomatic improvement does not occur within 2 to 3 days of antibiotic treatment, or symptoms recur within 2 wk of treatment. Urinary tract imaging is recommended in these cases.

BLOOD CULTURES

Cultures are obtained from hospitalized patients, but may not be routinely required in uncomplicated cases. Approximately 15% to 30% of patients with acute pyelonephritis are bacteremic. The elderly and individuals with complicated acute pyelonephritis are more likely to develop bacteremia and sepsis.

Urine cultures yield a causative organism in nearly all cases of acute pyelonephritis. Therefore, a positive blood culture may be diagnostically redundant. However, in unclear cases, or when an alternative diagnosis to acute pyelonephritis is considered, endometriosis, intraabdominal or psoas abscess, or cholangitis, blood cultures should be obtained.

RADIOLOGY

Most uncomplicated cases of acute pyelonephritis do not require imaging studies, unless symptoms do not improve or recurrence occurs or patient has prolonged fever (>72 hours) or persistent bacteremia. Abdominal radiographs (i.e., kidney, ureter, and bladder x-ray [KUB]) are of limited use in acute pyelonephritis, unless staghorn calculi are present. Retrograde or antegrade pyelography may be helpful in severe obstruction that is not evident after noninvasive evaluations. Voiding cystourethrography demonstrates vesicoureteral reflux and is generally performed routinely only in children.

Recommendations for radiologic tests:

- Healthy patients with uncomplicated pyelonephritis typically do not require radiologic evaluation when therapeutic responses occur within 72 hours of antibiotic therapy.
- If no response to therapy occurs within 72 hours, abdominal CT is the study of choice.
- Diabetics and immunocompromised patients should undergo precontrast and postcontrast abdominal and pelvic CT scans (Fig. 1) within 24 hours of diagnosis when the response to therapy is not prompt.
- Ultrasound (Fig. E2) is reserved for patients in whom exposure to contrast or radiation is considered hazardous. There is a high false-negative rate for renal abscess with ultrasound. In a prospective study of acute pyelonephritis of 213 patients submitted for CT/NMR study, 50 patients (23.5%) had a renal abscess, yet only two were detected by ultrasound.
- All other adults with complicated cases (i.e., history of stones or other urologic conditions, prior urologic surgery, repeated episodes of pyelonephritis) should be evaluated early by CT.
- Helical CT detects calculi with high sensitivity.
- Urologic imaging studies should be conducted in all young men and boys.

Although the risk of contrast nephropathy has declined substantially, exert caution during contrast administration to patients with chronic kidney disease or for those taking metformin. When evaluating kidney function, diagnostic decision-making must include eGFR trends, not serum creatinine, especially in the elderly. Patients with acute pyelonephritis and acutely elevated baseline serum creatinine may warrant CT imaging to rule out obstruction. If the risk of radiocontrast media administration outweighs its benefits, consider retrograde or antegrade pyelography.

The purpose of imaging is to identify underlying structural abnormalities, such as occult obstruction from a stone or abscess and serious complications such as emphysematous pyelonephritis. In a prospective study of 213 patients with acute pyelonephritis, there were no differences in frequency of fever, leukocytosis, C-reactive protein, pyuria, urine cultures, and duration of symptoms before hospitalization for positive or negative CT. Accordingly, systematic CT or magnetic resonance imaging is not required to exclude an anatomical abnormality. Such abnormalities cannot be predicted based on clinical, biochemical, or culture parameters.

Emphysematous pyelonephritis is a necrotizing infection that produces intraparenchymal kidney gas identifiable by renal imaging that is associated with high mortality. Risk factors include diabetes mellitus and/or urinary tract obstruction. Gas-forming bacteria, most commonly *E. coli*, produce gas that is usually restricted within Gerota fascia. If gas is localized to the kidney, mortality is 60%. If gas spreads to the perinephric space, mortality is 80%. In emphysematous pyelitis, the mortality is 20%. This must be differentiated from a renal abscess that can also be associated with a gas collection. With drainage and antibiotic treatment, a renal abscess has a favorable prognosis.

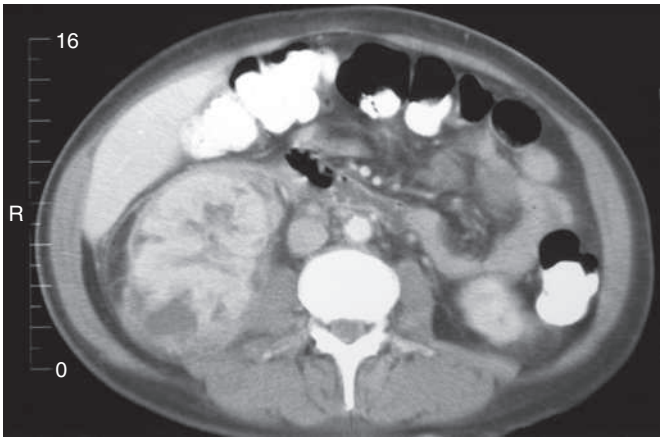

FIG. 1 Acute pyelonephritis: Contrast material–enhanced computed tomographic (CT) scan. The heterogeneous CT nephrogram shows the diffuse involvement of the right kidney. Stranding and some fluid are visible in the perinephric space with thickening of Gerota fascia. (From Skorecki K et al: *Brenner & Rector's the kidney*, ed 10, Philadelphia, 2016, Elsevier.)

LABORATORY TESTS

A basic metabolic profile and CBC with differential count are required for all patients with suspected acute pyelonephritis to estimate renal function. If the diagnosis is in doubt, other laboratory tests may be appropriate to clarify the differential diagnosis (e.g., lipase, transaminase, and β-HCG levels).

Rx TREATMENT

ACUTE GENERAL Rx

UNCOMPLICATED ACUTE PYELONEPHRITIS: Close outpatient follow-up is possible with minimal gastrointestinal symptoms and the ability to maintain fluid intake and oral medications. Prompt antibiotic therapy prevents progression of infection and must be initiated following acquisition of appropriate cultures. Begin empiric therapy based on risk of adverse effects, local community bacterial profiles, and resistance rates. Antibiotics are revised after urine culture results are available.

The concept of requiring long-term treatment of acute pyelonephritis has been questioned. Women with acute pyelonephritis were randomized to oral treatment with ciprofloxacin 500 mg twice daily for 7 days or 14 days, and 27% of these patients experienced bacteremia from *E. coli*. No differences in the cure rates were found (87% and 96%, respectively).

Outpatient regimens:

- Fluoroquinolones are preferred in communities where the local prevalence of resistant *E. coli* is ≤10%.
- Ciprofloxacin 500 mg by mouth twice daily or a single, 1000-mg dose in the extended-release form by mouth daily for 7 days.
- Levofloxacin 750 mg by mouth daily for 5 days.
- The initial dose may be administered intravenously (ciprofloxacin 400 mg or levofloxacin 500 mg).
- When a fluoroquinolone is contraindicated, alternative treatment with trimethoprim/sulfamethoxazole 160/800 mg PO twice daily for 10 to 14 days may be administered if the pathogen is susceptible. Recent data suggest that stopping treatment at 7 days may be equally effective.

Because of the high prevalence of resistance to oral beta-lactam antibiotics and trimethoprim/sulfamethoxazole, these agents usually are reserved for cases where susceptibility results are known. Additional factors (e.g., allergy history, potential drug–drug interactions, drug availability) may require empiric treatment with these agents before susceptibility results are known. For such cases, a long-acting, broad-spectrum parenteral drug (e.g., ceftriaxone 1 g or gentamicin 5 mg/kg) may be administered as a one-time dose or longer, until sensitivities of the organism are known. If the local prevalence of fluoroquinolone resistance to *E. coli* exceeds 10%, an initial intravenous dose of ceftriaxone or gentamicin is recommended, followed by an oral fluoroquinolone regimen.

Significant clinical improvement during appropriate empiric antibiotic therapy should occur within 48 to 72 hours. If improvement does not occur, a complication of acute pyelonephritis or an alternative diagnosis such as an abscess, emphysematous pyelonephritis, or an obstructing calculus should be considered. Any unexpected change in the clinical picture warrants immediate investigation with a CT scan, and with potential for surgical intervention.

COMPLICATED ACUTE PYELONEPHRITIS: Hospitalization is indicated for the following reasons:

- Toxic patients
- Complicated infections
- Diabetes or otherwise immunosuppressed
- Suspected bacteremia

Inpatient care includes supportive care, monitoring of culture results, adjustment of antibiotic regimen, and intravenous volume repletion as required. Intravenous antibiotics are continued until defervescence occurs and clinical improvement occurs. Next, there is conversion to an oral antibiotic regimen for a total duration of 10 to 14 days.

- Intravenous antibiotic options for more toxic patients pending cultures include ceftriaxone (1 to 2 g once daily), IV ciprofloxacin (400 mg every 12 hours) or IV levofloxacin (500 to 750 mg IV once daily), piperacillin/tazobactam (3.375 g IV every 6 hours), or carbapenems such as meropenem or imipenem (500 mg IV every 6 to 8 hours).
- Ceftazidime 1 to 2 g IV every 8 hours, piperacillin/tazobactam, or carbapenems are optimal choices for *Pseudomonas* due to this organism's increasing ciprofloxacin resistance.
- Aminoglycosides (2 mg/kg IV loading dose followed by 1 mg/kg IV every 8 to 12 hours, adjusted for kidney function) are potentially nephrotoxic, and are used only when there is no better alternative. Vancomycin 1 g IV every 12 hours, linezolid 600 mg IV or PO every 12 hours, or daptomycin 4 to 6 mg/kg IV daily for gram-positive cocci (e.g., enterococci, staphylococci).
- Ampicillin 1 to 2 g IV every 4 to 6 hours for ampicillin-sensitive enterococci with aminoglycoside for synergy. Urinary obstruction is promptly drained by nephrostomy tube. Surgical drainage of abscess formation(s).
- Pregnant females with acute pyelonephritis are hospitalized and treated initially with a second- or third-generation cephalosporin.

RENAL ABSCESSES (RENAL CARBUNCLES)

Cortical abscesses historically required surgical drainage; however, using current antibiotics is commonly sufficient for cure.

- Semisynthetic penicillin, cephalosporin, fluoroquinolone, or vancomycin, with guidance from culture and sensitivity results.
  1. Parenteral therapy for 10 to 14 days followed by oral therapy for 2 to 4 wk.
  2. Fever should resolve in 5 to 6 days and pain within 24 hours.
  3. If no clinical response occurs within 48 hours, percutaneous or open drainage should be considered. More extreme measures are occasionally required, including enucleation or nephrectomy.

CORTICOMEDULLARY ABSCESSES

- Parenteral therapy for at least 48 hours is typically successful.
- May require incision and drainage and possibly nephrectomy.
- If defervescence occurs, IV antibiotic treatment may be switched to complete a 2-wk course of oral antibiotic therapy.

PERINEPHRIC ABSCESSES

- Serious complication with mortality in the 25% to 50% range.
- Lesions require early recognition, surgical drainage, and parenteral antibiotics (not adequate alone) to reduce mortality.
- Initial antibiotic therapy should include an aminoglycoside and an antistaphylococcal agent.
  1. If *Pseudomonas* species grow in culture or are suspected, an antipseudomonal beta-lactam antibiotic should be administered with the aminoglycoside.
  2. For enterococcus, an aminoglycoside and ampicillin are recommended.
- Reported with tuberculosis or fungi as rare causes.
- Nephrectomy may be considered with clinical deterioration despite aggressive therapy.

CALCULI-RELATED INFECTIONS

Chronic pyelonephritis may lead to struvite stone formation, which is comprised of magnesium ammonium phosphate (struvite) and calcium carbonate-apatite. Formation requires infection with a urease-producing organism, such as *Proteus* or *Klebsiella*. Under normal conditions the urine is undersaturated with ammonium phosphate.

Symptoms directly attributable to struvite stones are uncommon. Most frequently, patients will present with symptoms of a urinary tract infection, mild flank pain, or hematuria. The stone may grow rapidly over a period of wks to mos and, if not adequately treated, can develop into a staghorn or branched calculus filling the entire renal pelvis and calyces.

Medical treatment for struvite stones is often ineffective and only indicated when surgery is not an option. Mortality is 28% with observation vs. 7.2% with surgical treatment. The most common surgical intervention is percutaneous nephrolithotomy. Open surgery, once the gold standard, is rarely used now.

Surgical intervention is generally recommended in patients with newly discovered stones or in patients with a solitary kidney or two equally functioning kidneys. Nephrectomy is a reasonable option in patients with a nonfunctional kidney, especially if chronic infection is present.

RENAL PAPILLARY NECROSIS

- Admission for parenteral antibiotics:
  1. Initial therapy should cover *E. coli*, *Enterobacter*, *Proteus*, and *Klebsiella* species, pending culture results.
  2. For more serious infections, *Pseudomonas* and *Enterococcus* should also be covered.
  3. Empiric therapy agent options include the following:
     a. Aminoglycosides
     b. Cefotaxime
     c. Ceftriaxone
     d. Ceftazidime
     e. Cefepime
     f. Piperacillin-tazobactam
     g. Imipenem-cilastatin
     h. Meropenem
     i. Ciprofloxacin
  4. Continue parenteral therapy until fever and clinical symptoms improve.

Xanthogranulomatous pyelonephritis: Rare variant of chronic pyelonephritis with destruction of renal parenchyma.

- Generally, unilateral
- Usually in individuals with obstructing stones
- CT is the diagnostic modality of choice and can provide staging information
- Can be confused with malignancy
- Treatment is surgical nephrectomy

CHRONIC Rx

- Repair underlying structural problems especially when kidney function is compromised.
  1. Reflux
  2. Obstruction
  3. Suspect nephrolithiasis
- Avoid urinary catheters.

DISPOSITION

- If pyelonephritis is uncomplicated with no significant GI symptoms, treatment may be initiated on an outpatient basis with close monitoring of therapeutic response(s) in 48 to 72 hours.
- If pyelonephritis is complicated and symptoms persist for >48 to 72 hours, admission is recommended for any of the following: Significant GI symptoms that preclude oral therapy, pregnancy, urinary tract obstruction, suspected renal or perinephric abscess, bacterial sepsis, diabetes or other immunocompromised states, recurrent or refractory pyelonephritis, or infection with unusual or antibiotic-resistant microorganisms.
- If sepsis is present, consider intensive care unit hospitalization.
- Acute pyelonephritis may be fatal when complications develop such as emphysematous pyelonephritis (mortality rate, 20% to 80%), perinephric abscess (mortality rate, 20% to 50%), or sepsis syndrome (>25% overall mortality rate).
- Acute deterioration or nonresponse to conventional therapy may be due to a complication, resistant organism, or unrecognized comorbidity.
- Diabetic patients with acute pyelonephritis are prone to bacteremia, longer hospital stays, and greater mortality. Diabetics should be considered complicated patients.
- Patients >65 yr of age experience greater mortality, septic shock, bedridden status, and immunosuppression. In males, mortality is also increased with the use of antibiotics in the previous mo.

REFERRAL

- General surgery or urology for suspected abscess
- Infectious disease for resistant organisms and poor response to routine antibiotic therapy as outlined
- Urology to correct underlying urologic problems (e.g., reflux and hydronephrosis)
- Nephrology consult for renal dysfunction or nephrolithiasis evaluation
- Critical care medicine if ICU admission is required

PEARLS & CONSIDERATIONS

- Consider acute pyelonephritis in patients with urinary symptoms, flank pain, and fever.
- Obtain a urinalysis and culture before starting empiric antibiotic therapy. Adjust treatment, pending antibiotic sensitivity testing.
- Evaluate clinical response in 48 to 72 hours during outpatient therapy. If there is no or delayed improvement, continue evaluation to rule out urinary tract obstruction.
- Urology consultation in all cases of urinary tract obstruction or detection of urinary tract gas (e.g., emphysematous pyelonephritis).
- Treat all diabetics as complicated acute pyelonephritis patients.

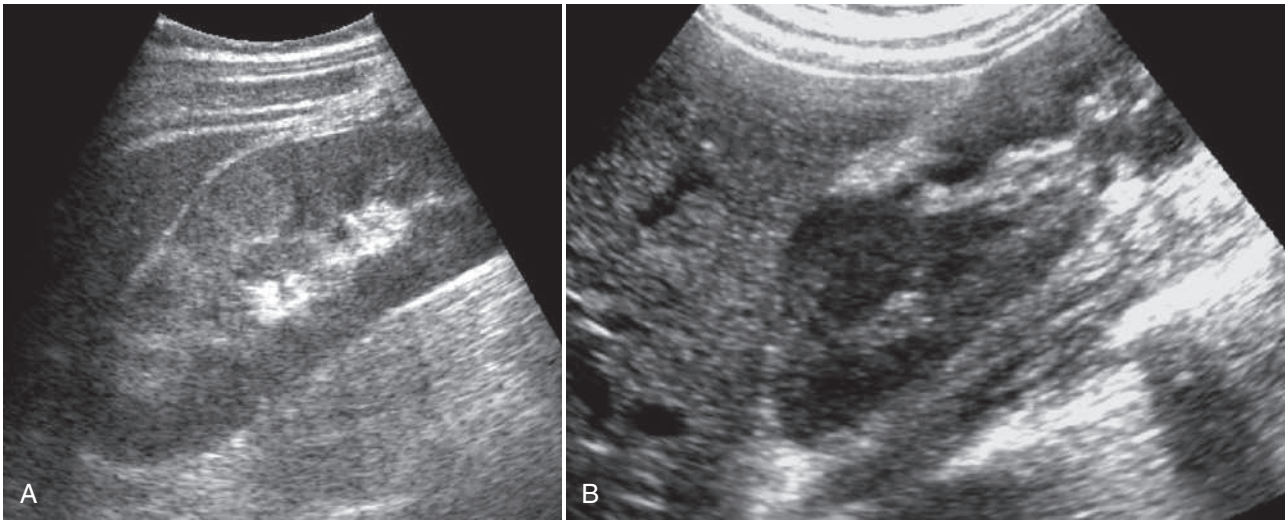

FIG. E2 Acute pyelonephritis. A, Subtle focal increased echogenic areas are seen in the anterior cortex of the right kidney. **B,** Single focal hypoechoic area is seen in the upper pole of the kidney in another patient. (From Rumack CM et al: *Diagnostic ultrasound*, ed 4, Philadelphia, 2011, Elsevier.)

Pyoderma Gangrenosum

BASIC INFORMATION

DEFINITION

Pyoderma gangrenosum (PG) is a rare, noninfectious neutrophilic dermatosis that presents as an inflammatory skin disease characterized by a papule or pustule that progresses to a painful ulcer with violaceous overhanging borders and a purulent base.

In contrast to its name, PG is neither an infectious nor gangrenous condition.

ICD-10CM CODE
L88 Pyoderma gangrenosum

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 10 cases per million people per yr.
PREDOMINANT AGE: Most common in young and middle-aged adults, with an average age of onset between 40 and 60 yr. Children can be affected.
PREDOMINANT SEX: Women are more frequently affected.
GENETICS: Familial cases of PG have been reported. PAPA syndrome is an autosomal dominant disorder linked to a mutation on chromosome 15q and characterized by pyogenic sterile arthritis, PG, and acne.
RISK FACTORS: Autoimmune diseases, particularly ulcerative colitis, Crohn disease, and rheumatoid arthritis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typically presents first as an inflammatory papule, pustule, vesicle, or nodule that rapidly and painfully progresses to an ulcer or erosion with tissue necrosis and enlargement of the area. The ulcer or erosion is surrounded by a violaceous border with a surrounding erythema (Fig. E1). Level of the pain is greater than expected based upon the appearance of the ulcer. Fever may be present.
- Classic PG is commonly found on the lower extremities (Fig. E2).
- Atypical PG occurs more frequently in the upper extremities, head, and neck. Atypical PG lesions begin as pustules and become plaques that may be studded with pustules.
- Peristomal PG lesions appear similarly to classic PG lesions; however, they occur around surgically created stomas such as in Crohn disease surgery.
- PG might also involve the genital area or might rarely affect extracutaneous sites (liver, lungs, intestines, cornea, heart, bones, CNS).
- As many as 30% of lesions occur via pathergy. Pathergy is the abnormal development of skin lesions at the sites of injury, including minor injuries. Pathergy-induced PG lesions can be misdiagnosed as cellulitis. Surgery can also induce pathergy.
- Some patients only present with a single episode of PG, while others can have multiple episodes or a chronic relapsing course.
- Approximately 50% of PG sufferers have an underlying systemic disease, including inflammatory bowel disease, myeloproliferative diseases, hematologic disorders (most frequently IgA monoclonal gammopathy), or inflammatory arthritis, pulmonary diseases, SLE, thyroid diseases, solid organ cancers, viral and autoimmune hepatitis, sarcoidosis, and major depression.

ETIOLOGY

Neutrophilic infiltration causing cutaneous damage seems to be a major part of the underlying mechanism. Abnormalities in neutrophil function, genetic variations, and dysregulation of the innate immune system are the primary factors causing PG.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

PG is often misdiagnosed due to its rareness, its similar appearance to other lesions, and a general lack of awareness of its existence.

- Cellulitis
- Vascular occlusion disorders
- Fungal infection
- Brown recluse spider bite
- Primary systemic vasculitides such as polyarteritis nodosa and granulomatosis with polyangiitis
- Malignancies such as squamous cell carcinoma, cutaneous lymphoma, and metastatic carcinoma
- Sporotrichosis
- Angiocentric T-cell lymphoma
- Cryoglobulinemia
- Drugs
- Livedoid vasculopathy
- Antiphospholipid syndrome
- Erythema nodosum
- Erythema elevatum diutinum

WORKUP

PG is a diagnosis of exclusion. Workup should include biopsy of lesions and evaluation for associated underlying illness such as inflammatory bowel disease, arthritis, or malignancy. History, particularly as to the timing and progression of the lesions and inciting injury, is particularly important, as well as the physical appearance and localization of the lesions.

LABORATORY TESTS

Skin biopsy is not diagnostic in itself because the findings are nonspecific. However, it may be helpful in excluding other diseases. Histopathologic findings show sterile dermal neutrophilia with or without mixed inflammation or lymphocytic vasculitis. Giant cells or leukocytoclastic vasculitis might be found. Other appropriate testing include rheumatologic lab work, hepatitis panel, or colonoscopy to evaluate for inflammatory arthritis, hepatitis, paraproteinemia, or inflammatory bowel disease (IBD). Tissue cultures should also be performed to rule out bacterial or fungal causes. Direct immunofluorescence studies might show deposition of IgM, C3, and fibrin in vessel walls.

IMAGING STUDIES

Consider colonoscopy and/or CT to evaluate for IBD. Chest radiography to evaluate for the

FIG. E1 Pyoderma gangrenosum. Note undermined hemorrhagic borders. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

FIG. E2 Pyoderma gangrenosum. Painful leg ulceration with an inflamed, undermined border. Note the pustule distal to the ulceration, often the earliest sign of a new site of involvement. The most common underlying condition in affected children is inflammatory bowel disease, although no underlying abnormality may be discovered. (From Paller AS et al: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Pyoderma gangrenosum. Partial response to treatment with cyclosporine. Note the persistent inflammation and evidence of healing ulcerations with residual cribriform scarring. The pyoderma gangrenosum healed fully and remained quiescent while the child was given etanercept, but this young boy developed Takayasu disease several yr after onset of the pyoderma gangrenosum despite ongoing inhibition of tumor necrosis factor alpha activity. (From Paller AS et al: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

presence of extracutaneous involvement and for possible infection before the initiation of immunosuppressive therapy.

Rx TREATMENT

The major treatment modalities revolve around wound care for the ulcers themselves, as well as either topical or systemic therapy (Fig. E3).

NONPHARMACOLOGIC THERAPY

Surgery or aggressive debridement should be avoided in PG lesions because the surgery can cause pathergy and worsen the lesions. When needed, grafting should be performed concurrently with systemic immune-modulating therapy to prevent worsening of the lesions.

ACUTE GENERAL Rx

Care may include one or more of the following:

- Topical wound care and moist healing
- Topical high-potency steroids (e.g., clobetasol)
- Topical immune modulators (e.g., tacrolimus)
- Systemic glucocorticoids (e.g., prednisone)
- Systemic immune modulators (e.g., cyclosporine)
- Antibiotics—only in cases of superinfection and if used with one of above
- Infliximab in patients with Crohn disease
- Dapsone or colchicine have shown some benefit
- Second-line treatment includes immunomodulatory drugs (thalidomide, azathioprine, mycophenolate mofetil, methotrexate, IV immune globulin)

CHRONIC Rx

Similar to above except for longer durations or in pulse therapy

COMPLEMENTARY & ALTERNATIVE MEDICINE

Not relevant

DISPOSITION

Can be treated in both inpatient and outpatient settings depending on severity and therapeutic modalities

REFERRAL

- Dermatology
- Rheumatology
- Gastroenterology, especially in cases of IBD-related PG
- Hematology

PEARLS & CONSIDERATIONS

COMMENTS

- PG is a diagnosis of exclusion that should only be made after other diseases in the differential have been ruled out and the patient has been evaluated for the associated diseases seen in >50% of cases.
- Postoperative pyoderma gangrenosum (PG at site of surgical incision) has less association with systemic disease than its nonpostoperative counterpart. It is often misdiagnosed as wound infection, and affected sites are often debrided, causing additional wound breakdown.

PATIENT & FAMILY EDUCATION

Support for PG can often be found in the support groups for associated diseases, particularly Crohn disease, ulcerative colitis, erythema nodosum, and rheumatoid arthritis.

Pyogenic Granuloma

BASIC INFORMATION

DEFINITION

Pyogenic granuloma is a benign vascular lesion of the skin and mucous membranes. The lesions are caused by capillary proliferation, generally the result of trauma.

SYNONYMS

Granuloma pyogenicum
Tumor of pregnancy
Eruptive hemangioma
Lobular capillary hemangioma
Granulation tissue–type hemangioma

ICD-10CM CODE
L98.0 Pyogenic granuloma

EPIDEMIOLOGY & DEMOGRAPHICS

- Common in children and young adults. Also found more frequently in pregnant women
- Equally prevalent in males and females, with no racial or familial predisposition
- Caused by trauma or surgery
- Gingival lesions occur more frequently during pregnancy

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Small (<1 cm), yellow to red, dome-shaped lesions
- May have surrounding scale at base (Fig. E1)
- Most commonly found on exposed surface of extremities, face, or on sites of trauma
- Often found on the gingiva during pregnancy (called *epulis*)
- Extremely friable, can easily ulcerate, and may bleed profusely with minor trauma

ETIOLOGY

- Trauma causing focal capillary growth. These lesions are neither infectious in etiology nor granulomatous in histology.
- Occurs more commonly in patients treated with certain medications (isotretinoin, indinavir, capecitabine, vemurafenib).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Amelanotic melanoma
- Bacillary angiomatosis
- Glomus tumor
- Hemangioma
- Irritated nevus
- Wart
- Kaposi sarcoma

WORKUP

Diagnosis is based on clinical history and appearance. Generally begins with trauma followed by the development of an erythematous papule. The lesion tends to bleed easily and develops over several days to weeks.

LABORATORY TESTS

Pathologic examination should be performed after excision to rule out melanoma.

TREATMENT

ACUTE GENERAL Rx

- Excision: Using 1% lidocaine for anesthesia, shave or curette at base and border. Follow with electrocauterization or cryotherapy.
- Pulsed-dye laser is also a safe and effective treatment modality.
- Pregnancy epulis generally resolves spontaneously after childbirth.
- Medication-related pyogenic granuloma may relapse after discontinuation or dose-lowering of culprit medication.

REFERRAL

Dermatology referral recommended if lesion recurs or multiple satellite lesions occur after excision.

PEARLS & CONSIDERATIONS

COMMENTS

- "Pyogenic granuloma" is a misnomer since these lesions are neither pyogenic nor granulomatous.
- Removal of entire lesion is essential because lesions may recur at the site of residual tissue.
- Patients and parents should be alerted to the possibility of recurrence after removal.
- Multiple satellite lesions occasionally develop near a primary pyogenic granuloma, usually after destruction of that lesion.

AUTHOR: **Fred F. Ferri, MD**

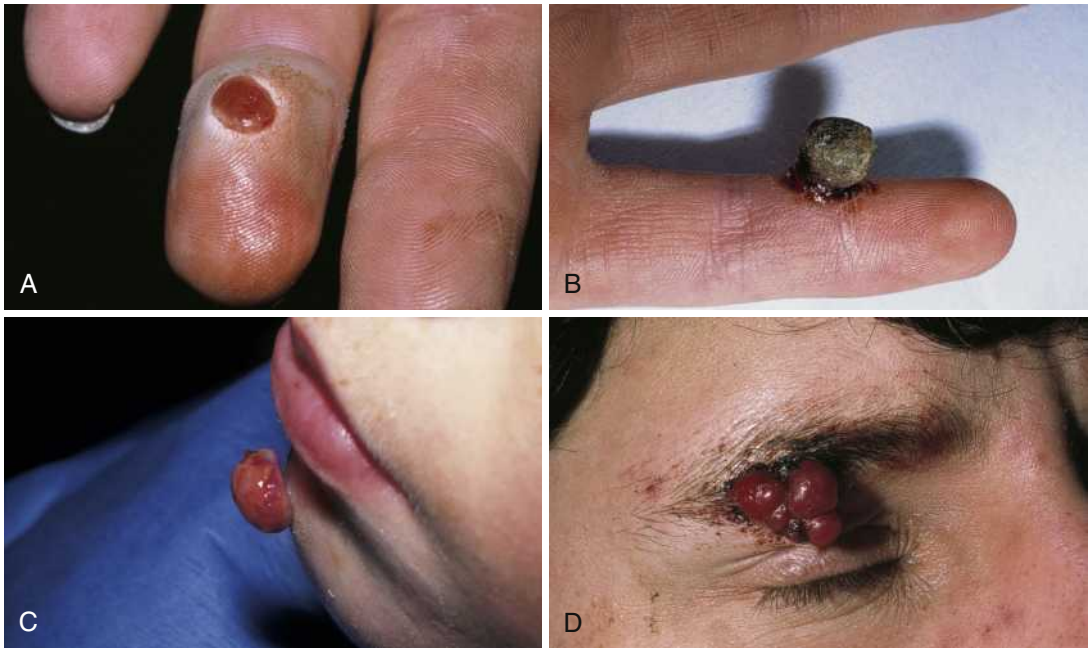

FIG. E1 Pyogenic granuloma. A, This is the classic appearance of a red, friable nodule growing rapidly on the finger. There is often a portion that extends under the skin laterally. **B,** Pyogenic granuloma on the finger. This lesion is more dry and crusted. **C,** Pyogenic granuloma on the chin of an adult. The fingers, lip, palms, soles, and face are typical sites. **D,** Pyogenic granuloma of the eyebrow. (From White GM, Cox NH [eds]: *Diseases of the skin, a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

Q Fever

BASIC INFORMATION

DEFINITION

Q fever is a zoonotic systemic febrile illness caused by *Coxiella burnetii* that may be acute or chronic. The concept of persistent localized disease may soon replace that of chronic Q fever.

SYNONYM

C. burnetii infection

ICD-10CM CODE
A78 Q fever

EPIDEMIOLOGY & DEMOGRAPHICS

- *C. burnetii* is found worldwide. Fig. E1 illustrates distribution in the U.S. in 2010.
- Common animal reservoirs are cattle, sheep, and goats.
- Pets such as cats, rabbits, and pigeons are also reservoirs.
- A parturient cat caused an outbreak in Nova Scotia just by delivering in the same room as a card game.
- Most cases are found in individuals who have direct contact with infected animals (e.g., farmers, veterinarians) or who are exposed to contaminated animal urine, feces, milk, or placental tissues.
- Q fever is seen more often in men than in women (ratio of 3:1).
- Its incidence in the U.S. is increasing, with more than 30 cases recently reported in U.S. military personnel recently deployed to Iraq and Afghanistan.
- Travel to Middle Eastern and African countries poses the greatest risk.
- *C. burnetii* is a CDC class B bioterrorism agent.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute Q fever presentation:
  1. Fever
  2. Pneumonia
  3. Hepatitis
  4. Meningoencephalitis
  5. Many cases are asymptomatic
- Chronic/persistent localized Q fever presentation (duration of infection >6 mo):
  1. Chronic endocarditis
  2. Vascular infection (aneurysms and vascular prostheses)
  3. Bone and joint infections (culture-negative osteomyelitis or prosthetic joint infection)
- Most common clinical symptoms:
  1. Chills
  2. Sweats
  3. Nausea
  4. Vomiting
  5. Cough, nonproductive
  6. Headache
  7. Fatigue
- Most frequent physical findings:
  1. Fever
  2. Inspiratory rales
  3. Purpuric rash
  4. Hepatomegaly
  5. Splenomegaly
- Infected pregnant women may be asymptomatic acutely, yet fetal wastage may occur

ETIOLOGY

- Q fever is caused by the Proteobacteria *C. burnetii.*
- *C. burnetii* is a gram-negative coccobacillus transmitted from arthropods to animals to human beings.
- The disease is acquired most often by inhalation of aerosols. In the lungs, it proliferates in macrophages and then gains access to the bloodstream, producing a transient bacteremia. Thereafter it can invade many organs, most commonly the lungs and liver.
- There is an incubation period of 3 to 30 days before systemic symptoms manifest.
- Persons with abnormal heart valves, prosthetic valves, and endovascular grafts are at high risk of progression to chronic Q fever. This includes individuals with bicuspid aortic valves.

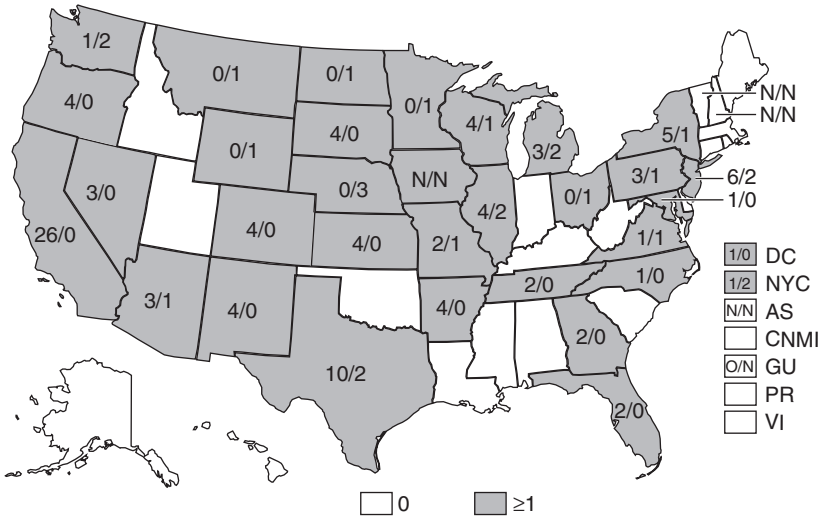

FIG. E1 Q Fever, acute and chronic. Number of reported cases: U.S. and U.S. territories, 2010. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, 2010, *MMWR Morb Mortal Wkly Rep* 59:1–111, 2012.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Q fever can have various presentations and must be in the differential diagnosis of fever, hepatitis, pneumonia, endocarditis, and meningitis. Situations that should prompt serologic testing for Q fever are described in Table E1.

WORKUP

- Complete blood count (CBC), erythrocyte sedimentation rate (ESR), and liver function tests
- Urinalysis
- Serology
- Chest radiography

LABORATORY TESTS

In acute Q fever:

TABLE E1 Situations that Should Prompt Serologic Testing for Q Fever

Acute Q Fever (Phase II Antigen and IgG ≥200 and IgM ≥50)
Fever in a patient in contact with ungulates
Unexplained prolonged fever (>7 days)
Granulomatous hepatitis
Fever and thrombocytopenia
Meningoencephalitis
Myocarditis
Erythema nodosum
Fever during pregnancy
Fever in a patient in contact with a parturient pet
Unexplained atypical pneumonia
Fever and an increase in transaminases (2-5 times the normal level)
Aseptic meningitis
Guillain-Barré syndrome
Pericarditis
Spontaneous abortion
Chronic Q Fever (Phase I Antigen and IgG ≥800 and IgA ≥100)
Blood culture–negative endocarditis
Patient with a valvulopathy and unexplained fever
Weight loss
Fatigue
Increased erythrocyte sedimentation rate
Increased transaminases
Thrombocytopenia
Patient with unusually rapid degradation of a prosthetic valve
Fever in a patient with a vascular aneurysm or prosthesis
Aseptic osteomyelitis
Chronic pericarditis
Multiple spontaneous abortions

From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

- CBC and white blood cell count are usually normal.
- Thrombocytopenia can occur (25%).
- Elevation of hepatic transaminases (two to three times the normal range) may be seen.
- Antibody detection by immunofluorescence assay is the most commonly used method because of its high sensitivity and specificity. Complement fixation (CF) shows a fourfold rise in titer between acute and convalescent samples.
- Polymerase chain reaction is desirable in early disease.
- Testing has been approved by the FDA and can be obtained from the CDC through the state health department.

In chronic Q fever (almost always endocarditis):

- ESR is elevated.
- Anemia is present.
- Microscopic hematuria.
- Blood cultures are almost always negative.
- MIF (microimmunofluorescence) titer of >1:800 to phase I antigen is diagnostic.

IMAGING STUDIES

- Chest radiographs are abnormal, showing segmental lobe consolidation.
- Pleural effusions (35%).
- Transthoracic echocardiography after the diagnosis of acute Q fever can be used to stratify risk of progression to endocarditis.
- PET/CT imaging may be instrumental in determining the focus of persistent localized or chronic Q fever.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Oxygen as needed in patients with pneumonia

ACUTE GENERAL Rx

- Acute Q fever can be treated with doxycycline (100 mg bid) for 14 to 21 days *or*
- Clarithromycin is the macrolide of choice for acute infection given intolerance of doxycycline
- Ofloxacin 200 mg PO q8h or ciprofloxacin 875 mg PO bid for 14 to 21 days
- Hydroxychloroquine plus doxycycline for endocarditis associated with Q fever
- Fluoroquinolones are recommended for suspected meningoencephalitis because of excellent penetration into the CNS
- Pregnant women may be treated with trimethoprim-sulfamethoxazole until the seventh month of gestation

CHRONIC Rx

- Chronic Q fever is treated with a combination of two antibiotics, doxycycline 100 mg bid and rifampin 900 mg qd.
- Doxycycline 100 mg bid and hydroxychloroquine 200 mg PO tid is the preferred therapy.
- Duration of treatment: 2 to 3 yr, at minimum 18 mo.
- Strongly consider prophylactic treatment for exposed individuals with preexistent high-risk cardiac lesions.

DISPOSITION

- Patients with acute Q fever respond well with antibiotics, with deaths rarely reported.
- Up to 20% of patients develop a post–Q fever fatigue syndrome.

Mortality rate in chronic Q fever endocarditis is high (24%). Many patients will need valve replacement surgery.

REFERRAL

Referral to an infectious disease expert is recommended in any cases of suspected acute or chronic Q fever.

Drug levels must be monitored and serial serologies evaluated.

REPORTING

Q fever has been a reportable disease in the U.S. since 1999. The CDC must be notified of cases.

PEARLS & CONSIDERATIONS

COMMENTS

- An acellular (CMR) vaccine is available in the U.S. However, vaccines that are available in other countries such as Australia have been more thoroughly studied.
- Infected patients do not require specific isolation precautions.
- Q fever derived its name in 1935 from Derrick, who was suspicious of a new disease during a series of acute febrile illnesses in abattoir workers of Queensland, Australia, justifying the name of Q fever (for "query").

Quadrilateral Space Syndrome

BASIC INFORMATION

DEFINITION

The quadrilateral space is formed by the long head of the triceps brachii muscle medially, the teres minor muscle superiorly, the teres major inferiorly, and the medial aspect of the humerus laterally (Fig. E1). The axillary nerve (along with the posterior humeral circumflex artery) courses through the quadrilateral space and innervates the teres minor and deltoid muscles as well as the posterolateral cutaneous region of the shoulder and upper arm.

Quadrilateral space syndrome (QSS) is a rare neurovascular syndrome characterized by shoulder pain, paresthesias, and point tenderness in the quadrilateral space due to compression or mechanical injury of the axillary nerve/posterior humeral circumflex artery in the quadrilateral space.

SYNONYMS

QSS
Lateral axillary hiatus syndrome
nQSS (neurogenic quadrilateral space syndrome)
vQSS (vascular quadrilateral space syndrome)

ICD-10CM CODE
Code varies with specific etiology of syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Rare in general population, more common in participants in sports that involve abduction and external rotation of upper extremities (baseball, volleyball, swimming, yoga) and in professional window cleaners. Most common age group is 20 to 40 yr and most commonly involves the dominant shoulder.

DOMINANT SEX: 7:1 male:female ratio, most likely due to traditional sex distribution in overhead or "throwing" athletics

RISK FACTORS: Professional athletes, window cleaners

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Diffuse shoulder pain (slow onset, intermittent, poorly localized, posterior and lateral aspect of the shoulder and arm)
- Nondermatomal neuropathic pain, usually in the posterior or lateral aspect of the shoulder/arm
- Weakness and numbness in the shoulder, most commonly in posterior region
- Vascular manifestations may be present (thrombosis, digital or hand ischemia, decreased pulses, pallor, splinter hemorrhages, cold intolerance)
- Symptoms aggravated by abduction and external rotation of the affected shoulder
- Throwing athletes notice pain with the late cocking phase of throwing in the overhead position
- Point tenderness over the quadrilateral space and, sometimes, deep palpation cause lateral shoulder pain or paresthesias
- A separate entity with isolated atrophy of the teres minor may also be present without sensory findings or deltoid weakness; this process is often asymptomatic and found incidentally with MRI

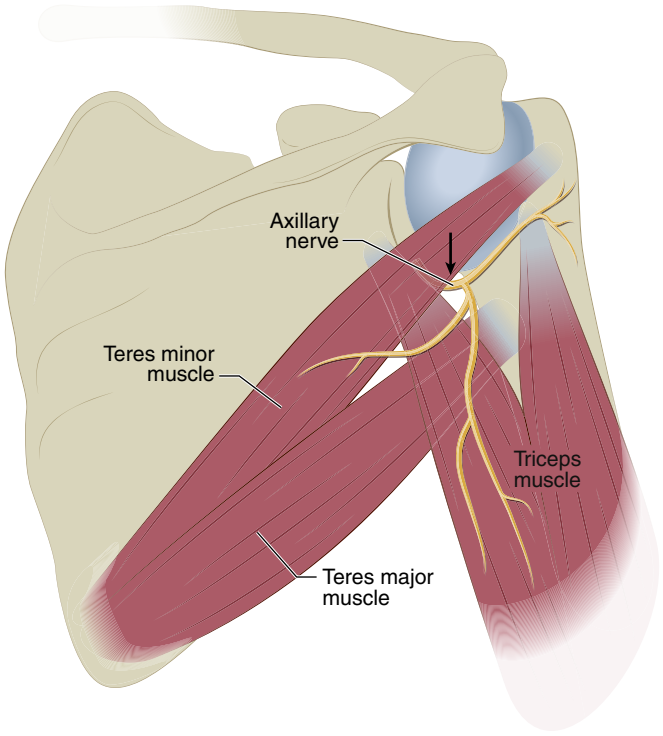

FIG. E1 Drawing of the quadrilateral space. View from the posterior aspect of the scapula demonstrating the four margins of the space: The teres minor muscle superiorly, the teres major muscle inferiorly, the medial aspect of the humerus laterally, and the triceps muscle medially. Note the axillary nerve passing though the quadrilateral space *(arrow)* and providing branches to the teres minor, triceps, and deltoid muscles. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, Saunders.)

ETIOLOGY

- Fibrous bands (generally posttraumatic) causing fixed structural compression of the quadrilateral space is the most common cause
- Muscle hypertrophy, especially in competitive athletes
- Repetitive mechanical injury to the posterior circumflex humeral artery
- Proximal humeral head fractures and callus formations
- Anterior shoulder dislocation resulting in traction and compression
- Soft tissue and osseous tumors, paralabral cysts
- Idiopathic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Brachial neuritis/plexopathy
- Thoracic outlet syndrome/referred pain from cervical radiculopathy
- Parsonage-Turner syndrome
- Thrombosis or aneurysmal formation in more proximal branches of axillary artery
- Adhesive capsulitis
- Rotator cuff or labral pathology
- Glenohumeral instability
- Proximal humeral fracture

WORKUP

- Magnetic resonance imaging (MRI)
- Computed tomographic angiography (CTA)
- Digital subtraction angiography (DSA)
- Magnetic resonance angiography (MRA)
- Ultrasound (US)
- Electromyography (EMG): Indicated primarily to rule out alternative diagnoses
- Quadrilateral space lidocaine block test: 5 ml of 1% lidocaine injected in the quadrilateral space with or without ultrasound guidance

LABORATORY TESTS

None indicated

IMAGING STUDIES

- CTA, DSA, MRA: Fixed posterior circumflex humeral artery (PCHA) occlusion due to thrombosis with or without distal embolization
- MRI: Denervation edema (acute, increased T2 and STIR signal and size) or fatty atrophy (chronic) of the teres minor and/or deltoid muscle

TREATMENT

NONPHARMACOLOGIC THERAPY

- Physical therapy: Soft tissue massage modalities, shoulder range of motion exercises, posterior rotator cuff strengthening, and scapular stabilization exercises
- Activity modification: Avoidance of abduction and external rotation

ACUTE GENERAL Rx

- Nonsteroidal antiinflammatory medications (NSAIDs), therapy, and activity modification

CHRONIC Rx

- Neurolysis/excision of existing fibrous bands or space-occupying lesions indicated after failed conservative treatment trial for at least 6 mo and a positive lidocaine test
- If fixed PCHA occlusion due to thrombosis: PCHA ligation with or without thrombolysis or surgical thromboembolectomy
  - Anticoagulation for 3 mo in patients with PCHA thrombosis

COMPLEMENTARY & ALTERNATIVE MEDICINE

None

DISPOSITION

In most cases, there is complete resolution of the symptoms with nonsurgical management and return to full activity after several wk

REFERRAL

Vascular surgery, orthopedics, neurology

AUTHORS: **Mohit Kukreja, MD,** and **E. Scott Paxton, MD**

BASIC INFORMATION

DEFINITION

Rabies is a fatal zoonotic illness caused by a number of species of neurotropic viruses in the Rhabdoviridae family and transmitted to human beings by the bite of an infected animal.

SYNONYM

Hydrophobia

ICD-10CM CODE
A82.9 Rabies, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Approximately two U.S. cases annually; 83 human cases or rabies in the U.S. from 1980 to 2015. Of these, 25 cases were imported rabies in people who were exposed to rabid animals in endemic nations and 5 cases were in tissue or organ transplantation recipients. Since 2008, nine persons have died from rabies in the U.S. following a rabies exposure abroad.

In the U.S., most cases are transmitted by bats; in the world, most cases are transmitted by dogs.

PREDOMINANT SEX: Men are more commonly affected (70% of cases)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation period is usually 1 to 3 mo in humans but can range from several days to 8 yr
- Shorter incubation period with bites on the face. Longer if extremities involved
- In domestic animals, a quarantine of 10 days is usually mandated
- Prodrome:
  1. Fever
  2. Headache
  3. Malaise
  4. Pain or anesthesia at exposure site
  5. Sore throat
  6. Gastrointestinal symptoms
  7. Psychiatric symptoms
- Acute neurologic period, with objective evidence of central nervous system involvement
- Two types of presentation
- "Furious" (encephalopathic) rabies (80% of cases):
  1. Extreme hyperactivity and bizarre behavior alternating with periods of relative calm
  2. Hallucinations, disorientation
  3. Seizures
  4. Paralysis
  5. Fear, pain, and spasm of the pharynx and larynx caused by drinking
  6. Coma, death
- "Dumb" (paralytic) rabies (20% of cases):
  1. Ascending flaccid paralysis
  2. Often prominent in the bitten limb
  3. Deep tendon and plantar reflexes lost
  4. Fasciculations

ETIOLOGY

- Rabies virus: Bullet-shaped viruses that belong to Rhabdoviridae family, genus *Lyssavirus*
- Cases in the U.S. are associated with:
  1. Bats
  2. Raccoons
  3. Foxes
  4. Skunks
- Small rodents (squirrels, mice, rats, chipmunks) and lagomorphs such as rabbits almost never have rabies and in the U.S. have never been a source of transmission of rabies to humans
- In 17 of 19 cases of rabies occurring in the U.S. from 1997 to 2006, exposure to bats was felt to be the source, although many did not have a clinically evident bite or scratch
- Imported cases are usually associated with dogs
- Unusual acquisition:
  1. By organ transplantation: Kidney, liver, arterial segment
  2. By aerosol transmission in laboratory workers and spelunkers

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Delirium tremens
- Tetanus
- Hysteria
- Psychiatric disorders
- Other viral encephalitides (Box E1)
- Guillain-Barré syndrome
- Poliomyelitis

BOX E1 Differential Diagnosis of Rabies

Viral-borne encephalitis
Herpes simplex virus (HSV-1)
Arboviruses (e.g., Eastern equine encephalitis, Western equine encephalitis, West Nile, Japanese encephalitis, California encephalitis, Rift Valley fever)
Enterovirus: Enterovirus 71
Cerebral malaria
Acute disseminated encephalomyelitis (ADEM)
Limbic encephalitis
Guillain-Barré syndrome
Poliomyelitis
Post-rabies vaccine encephalomyelitis
Tetanus
Botulism
Drugs
  Direct toxicity: Drug-induced psychosis (e.g., phencyclidine [PCP])
  Drug syndromes: Serotonin syndrome, neuroleptic malignant syndrome
  Drug withdrawal: Severe alcohol withdrawal
Florid mental illness
Rabies hysteria

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

WORKUP

- Antemortem diagnosis requires multiple specimens (saliva, skin that requires a full-thickness biopsy from posterior neck at the hairline, cerebrospinal fluid, serum) and multiple testing modalities: PCR, antibodies, immunofluorescence of viral antigens, viral culture.
- Animals submitted for rabies testing should be euthanized in a way that maintains the integrity of the brain.
- Negri bodies are eosinophilic cytoplasmic inclusions found in neurons. They are the best-known histologic feature of rabies usually found at postmortem examination.
- The national case definition for animal rabies requires laboratory confirmation by either:
  1. A positive DFA test (preferably performed on CNS tissue).or
  2. Isolation of rabies virus (in cell culture or in a laboratory animal).
- Fig. E1 describes an approach to assessing rabies exposure and initiating post-exposure prophylaxis (PEP) in the U.S.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Isolation of the patient to prevent transmission to others
- Supportive therapy

ACUTE GENERAL Rx

- No known beneficial therapy. A case report from 2005 describes a 15-yr-old girl who survived rabies and had been treated with a combination of ketamine, midazolam, ribavirin, and amantadine. It is known as the Milwaukee protocol. The protocol has been unsuccessful in over 40 subsequent reports and is considered ineffective.
- Other nonproven agents include interferon, corticosteroids, therapeutic coma, minocycline, and prevention of cerebral vasospasm. Research is ongoing in vitro and mice with favipiravir, a viral RNA polymerase inhibitor.
- Emphasis is placed on prophylaxis of potentially exposed individuals after an exposure (Table E1):
  1. Thorough wound cleansing and irrigation of the wound with soap and water as soon as possible. If available, a viricidal agent (e.g., povidone-iodine solution) should be used to irrigate the wounds.
  2. Active and passive immunization is most effective when used within 72 hr of exposure.
- Vaccinations: The CDC has recently recommended reducing the number of vaccine doses for postexposure prophylaxis. Current recommendations for rabies postexposure prophylaxis are as follows:
  1. Human diploid cell vaccine (HDCV) or purified chick embryo cell vaccine (PCECV) 1 ml IM (deltoid area) 1 each on days 0, 3, 7, and 14 in patients not previously vaccinated. In patients previously vaccinated, administer HDCV or PCECV 1

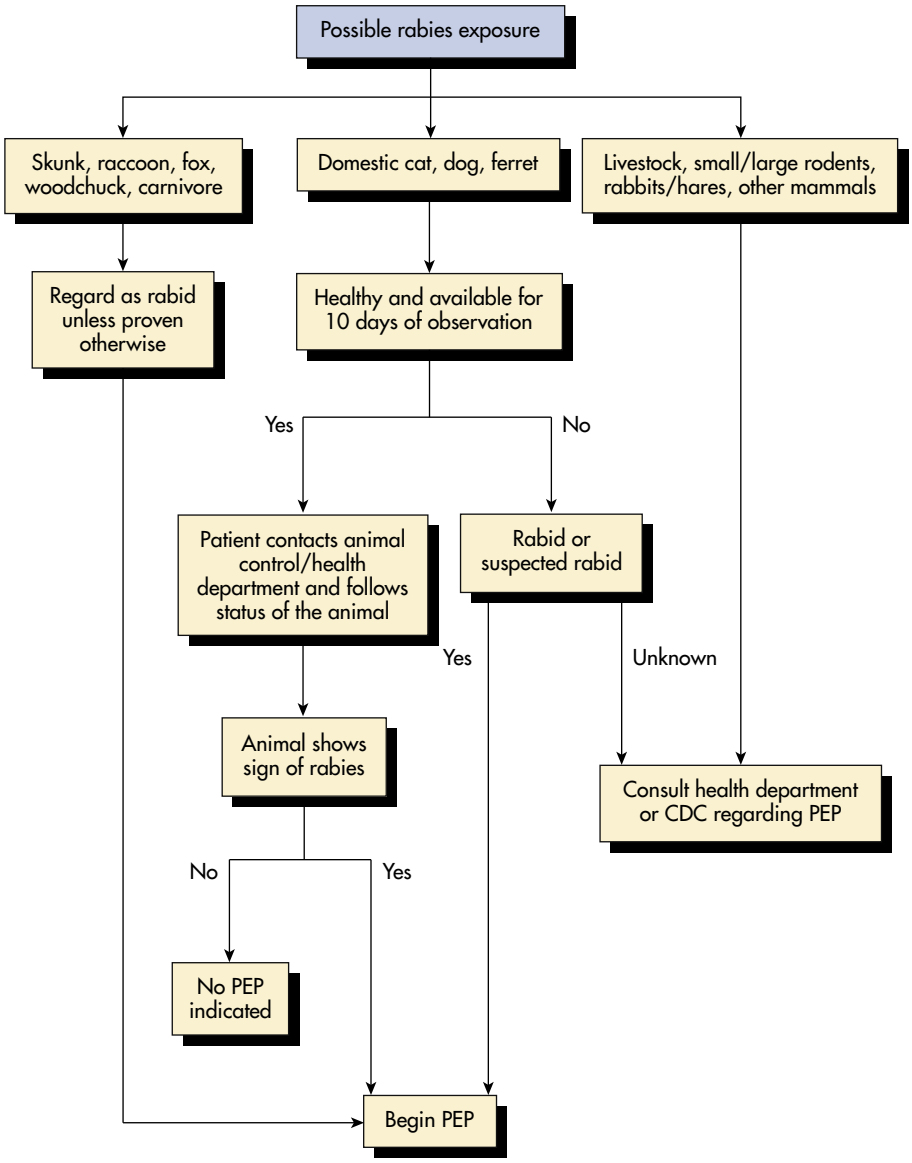

FIG. E1 Approach to assessing rabies exposure and initiating postexposure prophylaxis (PEP) in the U.S. *CDC,* Centers for Disease Control and Prevention. (From Adams JG et al: *Emergency medicine, clinical essentials,* 2nd ed, Philadelphia, Elsevier, 2013.)

TABLE E1 Regimen Examples for Preexposure and Postexposure Vaccination with Rabies Vaccines

Vaccination	Route	Days on Which Doses Are Given	Remarks
Preexposure	IM*	0, 7, 21, or 28	Standard U.S. and WHO three-dose regimen
	ID†	0, 7, 21, or 28	Economical, but not to be used in those taking antimalarial medications; unlicensed route in U.S.; WHO recommended
Postexposure‡	IM*	0, 3, 7, 14	Standard U.S. four-dose recommendation
	IM*	0 (2 doses), 7, 21	Used in some countries when RIG is not indicated; so-called 2-1-1 schedule
	ID†	0, 3, 7 (2 doses each), 28	Used in Thailand with PVRV, PCECV; so-called 2-2-2-0-1 schedule
	ID†,§	0 (8 doses), 7 (4 doses), 28, 90	Used in developing countries with HDCV, PCECV, or PVRV cell culture vaccines; so-called 8-0-4-0-1-1
Booster (for reexposure)	IM*	0, 3	Only after documented vaccination with cell culture vaccine¶
	ID†	0, 3	Only after documented vaccination with cell culture vaccine¶

HDCV, Human diploid cell vaccine; *ID,* intradermal; *IM,* intramuscular; *PCECV,* purified chick embryo cell vaccine; *PVRV,* purified Vero cell rabies vaccine; *RIG,* rabies immune globulin; *WHO,* World Health Organization.
*Together with rabies immunoglobulin.
†Give 0.1 ml, over the deltoids.
‡Give 0.5 ml (PVRV) or 1 ml, depending on the vaccine, into the deltoid.
§Give 0.1 ml at multiple sites (see text).
¶Or demonstrated presence of virus-neutralizing antibodies after other vaccines.
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

ml IM (deltoid area) 1 each on days 0 and 3. Human rabies hyperimmune globulin (RIG) 20 IU/kg body weight should be administered to persons not previously vaccinated. If anatomically feasible, the full dose should be infiltrated into the wound; any remaining volume should be given IM at a site separate from vaccine administration.

- Preexposure prophylaxis with HDCV or RVA (1 ml IM on days 0, 7, and 21 or 28) in individuals at high risk for acquisition:
  1. Veterinarians.
  2. Laboratory workers working with rabies virus.
  3. Spelunkers.
  4. Visitors to endemic areas.

DISPOSITION

Virtually always fatal. Rabies has one of the highest case/fatality ratios of any infectious disease.

REFERRAL

- To infectious disease consultant
- To local health authorities

PEARLS & CONSIDERATIONS

COMMENTS

- Most cases in the U.S. are caused by:
  1. Bat bites, often after minimal contact and inapparent exposure to infected bat saliva
  2. Dog bites occurring outside the U.S.
- Rare cases can be transmitted by mucous membrane contact with aerosolized virus (caves, laboratory-acquired cases)
- Rabies is preventable if exposed persons receive postexposure prophylaxis. Public understanding of rabies exposure risk from bat contact needs to be improved

BASIC INFORMATION

DEFINITION

Radial tunnel syndrome describes a form of compression neuropathy of the posterior interosseous nerve (PIN), a branch of the radial nerve, which presents mainly as pain over the dorso-radial aspect of the forearm (Fig. E1). The radial nerve branches 3 to 5 cm distal to the lateral epicondyle, into the superficial radial sensory nerve and PIN, which then enters the radial tunnel. The radial tunnel is approximately 5 cm and formed by the capitellum posteriorly; the brachioradialis, extensor carpi radialis longus, and brevis muscles anterolaterally; the brachialis muscle and biceps tendon medially; and ends at the proximal edge of the supinator. The PIN supplies the supinator and extensor muscles of the forearm (including the extensor carpi ulnaris, extensor digitorum, extensor digiti minimi, extensor indicis, extensor pollicis longus and brevis muscles, and abductor pollicis longus) as well as providing sensory innervation and proprioception to the wrist joint.

There is some controversy as to whether radial tunnel syndrome is a distinct entity or a variation of PIN syndrome. Patients may be found to have radial tunnel syndrome in the presence of forearm pain and localized tenderness over the radial nerve without weakness. Those with a primary complaint of weakness, rather than pain, are considered to have PIN syndrome.

SYNONYM

Radial pronator syndrome

ICD-10CM CODE

G56.30 Lesion of radial nerve, unspecified upper limb.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Rare, annual incidence is <0.03%
PEAK INCIDENCE: Unknown
PREDOMINANT SEX & AGE: Peak between age 30 and 50, likely slight female predominance, studies range from a female:male ratio of 1:1 to 6:1
GENETICS: Unknown
RISK FACTORS: Trauma and heavy manual labor, especially those who perform forearm extensions in pronation or supination

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients with radial tunnel syndrome present with pain in the proximal forearm, which is often exacerbated by activities that involve repetitive forearm pronation, wrist extension, and elbow extension. Pain is usually felt over lateral epicondyle of the humerus radiating distally toward radial styloid and thumb with maximum pain 3 to 5 cm distal to the lateral epicondyle.

Physical examination shows localized tenderness over the radial nerve distal to the lateral epicondyle. Pain is worsened with forearm pronation, wrist flexion, and elbow extension. The findings of localized forearm pain (especially over the mobile wad, or at the proximal edge of the supinator) with extension of the middle finger against resistance and pain with resisted supination are thought to be specific for radial tunnel syndrome. It is important to carefully examine the lateral aspect of the elbow, as radial tunnel syndrome is often missed. Tenderness over the supracondylar ridge is consistent with lateral epicondyle tendinopathy (tennis elbow), while tenderness 5 cm distal to the radiocapitellar joint is consistent with radial tunnel syndrome.

ETIOLOGY

- Localized compression sometimes related to repetitive movements or work-force injury; but often idiopathic
- Rarely, space-occupying lesions, such as lipomas, ganglions, or synovitis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lateral epicondylitis, which may often co-occur
- Posterior interosseous nerve syndrome

WORKUP

Anesthetic injection into the radial tunnel, which should provide pain relief, and can then serve as a marker for correct injection location for corticosteroids. Injections around the radial nerve should be undertaken with ultrasound guidance to minimize potential injury to nerve structures.

LABORATORY TESTS

N/A

IMAGING STUDIES

- Electromyogram (EMG)/nerve conduction velocity (NCV) studies are often done but rarely show evidence of radial tunnel syndrome. There is no consistent relationship between symptoms and study findings.
- MRI usually negative and has a limited role. Can be helpful in ruling out lipoma/ganglion as cause of compression, or rarely show denervation/edema within supinator/extensor.

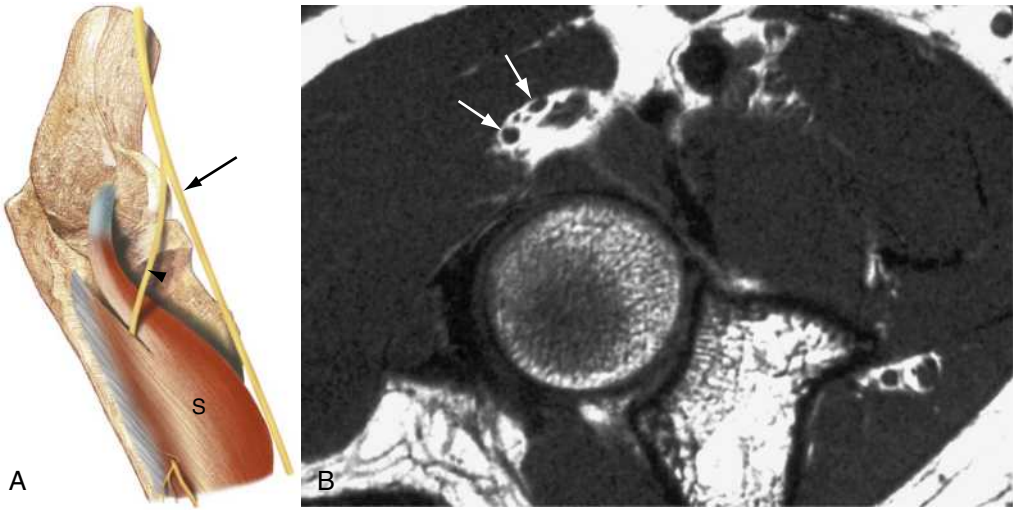

FIG. E1 Normal anatomy of the radial nerve in the elbow area. A, Lateral illustration. The radial nerve courses distally in the anterior aspect of the elbow and arm. At the level of the elbow joint it divides into two branches: The superficial sensory branch *(arrow)* and the deep motor branch or posterior interosseous nerve *(arrowhead)*. The posterior interosseous nerve penetrates the supinator muscle *(S)* between the superficial and the deep layers (the arcade of Fröhse). **B,** Axial T1-weighted magnetic resonance image. (From Pope TL et al: *Musculoskeletal imaging*, ed 2, Philadelphia, 2015, Elsevier.)

TREATMENT

ACUTE GENERAL Rx

- Wrist splinting (generally at nighttime), gentle stretching, and activity modification (limiting repetitive pronation and supination)
- NSAIDs
- Corticosteroid injection: Diagnostic and therapeutic

CHRONIC Rx

Activity modification

DISPOSITION

- Conservative treatment and steroid injection results in about 60% of patients being pain free at 2 yr.
- Radial tunnel release surgery has been reported to be effective in 70% of patients.

REFERRAL

Surgical referral for radial tunnel release surgery—if conservative measures fail >3-mo period

PEARLS & CONSIDERATIONS

COMMENTS

Radial tunnel syndrome coexists with lateral epicondylitis in about 5% of patients. In lateral epicondylitis, pain is directly over lateral epicondyle rather than more distal, as in radial tunnel syndrome. Muscle weakness, if present, is clinically insignificant.

PREVENTION

Activity modification and avoidance of forearm pronation, wrist flexion, and elbow extension

BASIC INFORMATION

DEFINITION

Radiation is the emission of energy as electromagnetic waves or moving subatomic particles. It can be natural or man-made. Natural radiation can come from a cosmic source, such as the sun, or a terrestrial source, such as naturally occurring radionuclides. Man-made radiation can come from nuclear reactors and x-ray machines. There are two types of radiation, ionizing radiation and nonionizing radiation, both of which have the potential for human tissue injury. Ionizing radiation has more energy and can cause a direct effect with its interactions on cellular molecules such as DNA bases, proteins, and cellular membranes, or by indirectly affecting these molecules by influencing other molecules, primarily water, to generate free radicals. The different types of ionizing radiation include alpha and beta particles, gamma rays, and x-rays. An alpha particle is a helium nucleus without the electrons, two protons, and two neutrons. A beta particle is either an electron or a positron (which is a positively charged electron). Gamma rays and x-rays are photons of pure energy, and their biological effects are due to ionization. Nonionizing radiation has less energy and causes damage to biological tissues and aforementioned cellular components through the transfer of thermal (heat) energy. Examples of nonionizing radiation include radio waves, microwaves, and sun exposure. The most important risk from radiation exposure is cancer. Other risks include genetic mutations and birth defects.

UNITS OF RADIATION (TABLE E1)

The amount of radiation absorbed by the patient's tissues is highly predictive of its biological effects.

- Roentgen (R): A measure of radiation that quantifies the electrical charge; it generates in a volume of air divided by the air's mass (coulomb/kg).
- Grays (Gy): Energy deposited per unit mass. 1 J/kg of tissue = 1 Gy.
- Radiation absorbed dose (rad): Amount of radiation absorbed by a material; 1 rad = 1/100 gray (Gy).
- Roentgen equivalent man (rem): A measure of radiation biologic damage. It is the product of the absorbed dose and a quality factor. The quality factor considers differential sensitivity among tissues (Table E2).
- Sievert (Sv): Equal to 100 rem.
- Lethal dose of radiation (LD 50): Amount of radiation associated with death in 50% of those similarly exposed.
- Dose rate: Refers to amount of radiation delivered per unit of time and is often measured in Gy/hr or rads/hr.
- Effective dose: A measurement of dose that considers the type of radiation and the relative sensitivity of the exposed organ/tissue, as determined by the weighting factor for that organ/tissue.

SYNONYMS

For large exposures (deterministic, or nonstochastic, effects of radiation):
Acute radiation syndrome
Radiation sickness
Chronic low-dose exposures produce stochastic effects. This has no common synonyms

ICD-10CM CODES

W88	Exposure to ionizing radiation
T66	Unspecified effects of radiation
T66.XXXA	Radiation sickness, unspecified, initial encounter
T66.XXXS	Radiation sickness, unspecified, sequela
W88.8XXA	Exposure to other ionizing radiation, initial encounter
W90.2XXA	Exposure to laser radiation, initial encounter
W90.8XXA	Exposure to other nonionizing radiation, initial encounter
X39.08XA	Exposure to other natural radiation, initial encounter
Y63.2	Overdose of radiation given during therapy
Y63.3	Inadvertent exposure of patient to radiation during medical care
Z51.0	Encounter for antineoplastic radiation therapy
Z57.1	Occupational exposure to radiation
Z77.123	Contact with and (suspected) exposure to radon and other naturally occurring radiation
G62.82	Radiation-induced polyneuropathy
J70.0	Acute pulmonary manifestations due to radiation
J70.1	Chronic and other pulmonary manifestations due to radiation
K12.33	Oral mucositis (ulcerative) due to radiation
K52.0	Gastroenteritis and colitis due to radiation
K62.7	Radiation proctitis

EPIDEMIOLOGY & DEMOGRAPHICS

- High-dose radiation is limited to nuclear disasters.
- Low-dose radiation occurs from naturally occurring radiation (i.e., radon, terrestrial

TABLE E1 Radiation Exposure Units of Measurement

	SI Units	Common Units	Conversion Equivalents
Radioactivity	Becquerel (Bq)	Curie (Ci)	1 Bq = 3.7×10^{10} Ci
Absorbed dose	Gray (Gy)	Rad	1 rad = 0.01 Gy
Dose equivalent	Sievert (Sv)	Rem	1 Rem = 0.01 Sv
Exposure	Coulomb/kg (C/kg)	Roentgen (R)	1 R = 0.000258 C/kg

TABLE E2 Symptoms, Therapy, and Prognosis of Whole-Body Ionizing Radiation Injury

	0-1 SV	1-2 SV	2-6 SV	6-10 SV	10-20 SV	>50 SV
Therapeutic needs	None	Observation	Specific treatment	Possible treatment	Palliative	Palliative
Vomiting	None	5%-50%	>3 Gy, 100%	100%	100%	100%
Time to nausea, vomiting	—	3 hr	2 hr	1 hr	30 min	<30 min
Main locus of injury	None	Lymphocytes	Bone marrow	Bone marrow	Small bowel	Brain
Symptoms and signs	—	Moderate leukopenia, epilation	Leukopenia, hemorrhage, epilation	Leukopenia, hemorrhage, epilation	Diarrhea, fever, electrolyte imbalance	Ataxia, coma, convulsions
Critical period	—	—	4-6 wk	4-6 wk	5-14 days	1-4 hr
Therapy	Reassurance	Observation	Transfusion of granulocytes, platelets	Transfusion, antibiotics, bone marrow transplantation	Fluids and salts, possible bone marrow transplantation	Palliative
Prognosis	Excellent	Excellent	Guarded	Guarded	Poor	Hopeless
Lethality	0	0	0%-80%	80%-100%	100%	100%
Time of death	—	—	2 mo	1-2 mo	2 wk	1-2 days
Cause of death	—	—	Infection, hemorrhage	Hemorrhage, infection, pneumonitis	Enteritis, infection	Cerebral edema

Modified from Phillips TL: Radiation injury, In Wyngaarden JB et al [eds]: *Cecil textbook of medicine,* ed 24, Philadelphia, 2012, Saunders.

and cosmic radiation), man-made radiation including radiation in medicine (CT, x-ray, radiopharmaceuticals), and radiation in industry such as nuclear power and radioactive waste.
- There is an increase in exposure to low-dose radiation among average Americans due to the expansion of medical imaging, which has been increasing continuously over the past 30 yr.
- Younger persons are particularly susceptible to injury from radiation exposure.
- The average natural background radiation is about 3.6 mSv per yr.
- Epidemiology of cumulative low-level radiation is not well understood and is based on the following two dose-dependent theories:
  1. Stochastic effects of radiation exposure: There is a probability of damage-increased effect with dose, but there is no dose threshold, and severity is not dose related.
  2. Deterministic effects: Severity of damage is dose related but with a threshold below which there is no negative outcome.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Low-level radiation: Low-level radiation over time may present clinically with various malignancies that may be at increased incidence compared with background rates of malignancies, but there remains much controversy.
- Exposure to radiation from medical imaging tests has been implicated in secondary cancer. The rate of cancer has been found to be dose dependent, and exposure increases incremental risk. Data suggest clear evidence of increased radiation-induced cancer risk at doses >100 mSv, but the risk is more controversial with doses of 10 to 100 mSv, which is the range of most medical imaging, including CT.
- Occupational radiation exposure has been associated with cancer risk, both non-CLL leukemia and other cancers. Occupational exposure has been implicated to cause cataracts in medical professionals who get exposure in a dose-dependent relationship.
- Acute radiation syndrome (ARS): An acute illness caused by a high dose of penetrating radiation (≥0.7 Gy) over a large portion of the body delivered in a short period of time (usually minutes). Effects of acute radiation exposure are better studied based on previous nuclear disasters and are summarized in Table E3. The four stages of ARS are:
  1. Stage 1 (prodromal phase 0 to 2 days after exposure): Flulike syndrome with anorexia, apathy, nausea, vomiting, diarrhea, fever, tachycardia, and/or headache, usually occurring within 48 to 72 hr.
  2. Stage 2 (latent phase 2 to 20 days after exposure): A short period characterized by improvement in symptoms, lasting for several days to 1 mo. Duration is inversely related to dose of radiation received and may be absent at severe doses of 10 Gy or greater. Acute radiation pneumonitis may manifest characterized by dry cough and dyspnea.
  3. Stage 3 (manifest illness phase 21 to 60 days): If the person survives this stage, recovery is likely. There are three classic ARS syndromes:
     a. Hematopoietic syndrome: Effects can occur with exposure >1 Gy and include pancytopenia, increased infection risk, and bleeding disorders.
     b. Gastrointestinal syndrome: Radiation induces loss of intestinal crypts, resulting in abdominal pain, nausea, vomiting, anorexia, and diarrhea (5 to 12 Gy).
     c. Central nervous system: Symptoms occur with a very high level of acute radiation (>10 Gy) and include ataxia, confusion, seizures, and coma due to damage of the blood-brain barrier, interstitial edema, and acute inflammation.
     d. Cutaneous syndrome: Findings include erythema, edema, and dry desquamation of the skin that can involve the dermis, subcutaneous tissue, and even muscle or bone.
  4. Stage 4: Death or recovery, lasting wks to mos. Radiation exposure of greater than 5 Gy results in a high risk of death. No individual has survived doses of greater than 10 Gy of exposure. If patients survive, they need lifelong follow-up because of the potential for unusual infections, organ dysfunction, and carcinogenesis.
     a. Radiation "burn": Prolonged exposure from fluoroscopy can lead to acute radiodermatitis presenting as red patches but over a few wks can lead to tissue necrosis.
     b. Radiation-induced lung fibrosis may also arise in doses to the lungs in the range of 8 to 10 Gy. Such injury can lead to tissue hypoxia.
- The clinical course of acute radiation syndrome depends on absorbed radiation dose and distribution. Although all tissues composed of short-lived cells are affected by radiation, the most sensitive of cells in adults include:
  1. Crypt cells in the intestines
  2. Hematopoietic cells in the bone marrow
  3. Spermatocytes in the testis

PROGNOSIS

ACUTE RADIATION SYNDROME:
- Exposure <1 Gy: Almost certain survival
- Exposure 1 to 2 Gy: 90% survival with medical care
- Exposure 2 to 3.5 Gy: Probable survival with medical care
- Exposure 3.5 to 5.5 Gy: 50% survival with medical care
- Exposure 5.5 to 10 Gy: Probable death, even with ICU-level care, reverse isolation, and possible hematopoietic stem cell transplantation
- Exposure >10 to 12 Gy: Certain death

CHRONIC LOW-DOSE EXPOSURE: Excess cancer not detected below 100 mSv

Dx DIAGNOSIS

ACUTE RADIATION SYNDROME:
- Diagnosis usually accompanies a nuclear disaster and therefore suspicion is already very high. Diagnosis may be difficult, as prodromal stage may occur hours to days after exposure.
- Workup can include measuring radiation levels at site. Estimation of exposure may be accomplished using tools such as the METREPOL (Medical Treatment Protocols for Radiation Accident) clinical grading system, which is useful for prognosis.
- Laboratory studies: In the acute setting, serial CBCs with differential, chromosome analysis.
- Diagnostic imaging: Brain imaging.

TABLE E3 Dose Estimates for Common Life and Medical Activities

Activity	Dose Estimate
Natural background and human-made radiation (annual average dose equivalent, including radon)	360 mrem
Diagnostic chest x-ray	6-10 mrem
Flight from Los Angeles to Paris	800 mrem
Barium enema	5 mrem
Smoking 1.5 packs per day for 1 yr	16,000 mrem = 16 rem
Heart catheterization	45,000 mrad = 45 rad = 0.45 Gy
Mild acute radiation syndrome	200 rad = 2 Gy
LD_{50} for acute whole-body irradiation managed without supportive care	450 rad = 4.5 Gy
Occupational limit for a radiation worker	5 rem = 0.05 Sv
Limit of a member of the public	0.1 rem = 0.001 Sv = 1 mSv

Gy, Gray; *LD50,* median lethal dose; *mrad,* millirad; *mrem,* millirem; *mSv,* millisievert; *rad,* radiation absorbed dose; *rem,* roentgen equivalent man; *Sv,* sievert.

Modified from Goans RE: Medical management of radiation incidents, In Shannon MW et al [eds]: *Haddad and Winchester's clinical management of poisoning and drug overdose,* ed 4, Philadelphia, 2007, Saunders.

- Typical syndromes are hematopoietic (doses >3 Gy), gastrointestinal (doses 5 to 12 Gy), and cerebrovascular (10 to 12 Gy).

CHRONIC LOW-DOSE EXPOSURE:

- Currently impossible to determine whether a subsequently diagnosed malignancy is radiation induced. Recent study has shown that long-term exposure to low-dose radiation can lead to a small increase in the risk of leukemia.
- Workup is for underlying malignancy evaluation.
- Research is being performed to look at the effect of chronic low-dose exposure on diseases other than malignancy, such as stroke and heart attack.

ETIOLOGY

ACUTE RADIATION SYNDROME: Usually nuclear disaster

CHRONIC LOW-DOSE EXPOSURE: The average annual dose to residents of the U.S. is approximately 3.6 mSv.

- Cosmic: Positive-charged ions that interact with atmosphere to create secondary radiation
- Terrestrial: Radon, potassium-40, thorium, and uranium
- Man-made: Medical radiation including x-rays, CT scans, PET scans, nuclear stress tests, fluoroscopy, nuclear power, radioactive waste

Rx TREATMENT

- For all accidental radiation contamination, such as nuclear medicine materials, the following decontamination steps are considered mandatory:
  1. Perform at site of exposure unless there is continued radiation exposure.
  2. Remove all clothing (and treat as radioactive waste). Providers should use strict isolation precautions, including donning of gown, mask, cap, double gloves, and shoe covers, when evaluating and treating contaminated patients.
  3. Wash patient with mild soap (neutral pH) and lukewarm water. Dispose of contaminated water as radioactive waste.
  4. Scrub any open wound.
  5. Depending on the situation, the regional emergency response system should be called for additional measures such as evacuation.
- Management of acute radiation syndrome:
  1. Establish IV access.
  2. Monitor physiologic signs.
  3. Manage the airway.
  4. Manage burns.
  5. Identify and treat other injuries.
  6. Obtain CBC with differential, HLA typing prior to any transfusions.
  7. Repeat CBC every 2 to 3 hr for two to three times to assess lymphocyte depletion.
  8. Confirm initial dose estimate using chromosome aberration cytogenetic bioassay when possible.
  9. Provide analgesia and treat vomiting with antiemetics (e.g., ondansetron).
  10. Manage bleeding and transfuse if necessary.
  11. Document skin changes to monitor for radiation skin damage.
  12. Consult with radiation, radiotherapy, and hematology experts.
  13. Diagnose and treat sepsis. Administration of antibiotics reduces the mortality rate. In nonneutropenic patients, use of antibiotics should be reserved for obvious foci of infection secondary to extensive burns, penetrating wounds, and/or abdominal/visceral trauma.
  14. In the setting of neutropenic fever secondary to radiation exposure, one should follow Infectious Diseases Society of America (IDSA guidelines), including fluoroquinolone with streptococcal coverage, an antiviral agent, and an antifungal agent.
  15. Thyroid protection should be considered with exposure to radioactive iodine exposure (e.g., nuclear reactor incident, atomic blast). Prevention of significant uptake is achieved with administration of potassium iodide (KI) within 6 hr of exposure. Repeat doses (every 24 hr) of KI can be administered if radioactive iodine exposure is expected for more than 24 hr.
  16. Consider colony-stimulating factors (CSFs). In any adult with whole-body or significant partial body exposure >3 Gy, treatment with CSFs should be rapidly initiated (e.g., G-CSF or filgrastim, 5 mcg/kg of body weight per day). CSFs may be withdrawn when the absolute neutrophil count reaches a level greater than 1.0×10^9 after recovery from the nadir.
  17. Consider transfusion for radiation-associated bone marrow suppression and GI-associated blood losses. Transfusion thresholds are based upon transfusion guidelines for patients receiving chemotherapy. Consider leukoreduction and irradiation of blood products to prevent graft-versus-host disease.
  18. Consider stem cell transplantation in people with exposure dose of 7 to 10 Gy who do not have significant burns or other major organ toxicity and who have an appropriate donor.
  19. Provide counseling; 75% of individuals exposed to nuclear weapon detonations exhibit some form of psychological symptoms, ranging from insomnia to difficulty concentrating and social withdrawal.
  20. Table E4 summarizes radiation countermeasures for treatment of internal contamination.
- Chronic low-dose exposures: Treatment of radiation-induced organ damage would not differ significantly from non–radiation-induced cancers, cataracts, or skin lesions.
- Late sequelae of radiation exposure include cardiac manifestations such as restrictive cardiomyopathy, constrictive pericarditis, and coronary artery disease. Those at high risk are patients with a radiation exposure of >35 Gy to the heart and usually manifests after 10 yr of radiation exposure.

PEARLS & CONSIDERATIONS

COMMENTS

- Humans are consistently exposed to background/naturally occurring radiation.
- The main concern of radiation exposure is increased risk of cancer.
- X-rays and gamma rays are types of ionizing radiation that can have deleterious biologic effects by damaging DNA.
- The ionizing radiation from medical imaging procedures is not negligible. Since the early 1980s, the per capita dose of radiation from medical imaging has increased by a factor of nearly 6. There is concern that the greater exposure to low-dose radiation due to increased medical imaging will lead to a higher incidence of radiation-induced cancer.
- Efforts to reduce risk of radiation from imaging include justification, optimization, and limitation for imaging procedures.
- Optimization refers to a guiding principle named As Low As Reasonably Achievable (ALARA), which recommends that diagnostic imaging be protocoled to the lowest possible dose to the patient.
- It is difficult to make a link between exposure to chronic low-level radiation and a specific malignancy in an individual.
- Positioning patients for fluoroscopy procedures and monitoring amounts of x-ray radiation are very important to prevent radiation burns.

TABLE E4 Radiation Countermeasures for Treatment of Internal Contamination

Medical Countermeasure	Administered for	Mechanism of Action	Route of Administration	Dosage	Duration of Treatment
Aluminum carbonate	Phosphorus (P-32)	Phosphate binder	PO	600-mg tablet tid or 400 mg/5 ml tid	
Aluminum hydroxide	Radium (Ra-226) Strontium (Sr-90)	Blocks intestinal absorption	PO	*Adults:* 60-100 ml (1200 mg) *Children:* 50 mg/kg, not to exceed the adult dose	Give one dose within 24 hr of radionuclide intake
	Phosphorus (P-32)	Phosphate binder	PO	600 mg tablet tid or 320 mg/5 ml tid	
Barium sulfate	Radium (Ra-226) Strontium (Sr-90)	Blocks intestinal absorption	PO	100-300 g (as a single dose in 250 ml water)	Give one dose within 24 hr of radionuclide intake
Calcium carbonate	Radium (Ra-226) Strontium (Sr-90)	Competes for bone binding sites	PO	Use as directed on label	Begin therapy within 12 hr of radionuclide intake if possible
Calcium gluconate	Radium (Ra-226) Strontium (Sr-90)	Competes for bone binding sites; phosphate binder	IV	5 ampoules (500 mg Ca/amp) in 500 ml 5% D5W; infuse over 4-6 hr	6 days; begin therapy within 12 hr of radionuclide intake if possible
Calcium phosphate	Radium (Ra-226) Strontium (Sr-90)	Increases excretion	PO	1200 mg	Give one dose within 24 hr of radionuclide intake
Deferoxamine (DFOA)	Plutonium (Pu-239)	Chelating agent	IM (preferred route)	2 ampoules (500 mg DFOA/amp)	• Give a single dose, then obtain bioassay to assess residual body burden of Pu-239 • Repeat as indicated: 500 mg IM (preferred) or IV q4h × 2 doses, then 500 mg IV q12h for 3 days
			IV (slow infusion)	2 ampoules (500 mg DFOA/amp) at 15 mg/kg/hr	
Dimercaprol (BAL)	Polonium (Po-210)	Chelating agent	IM (300 mg/vial for deep IM injection only)	2.5 mg/kg qid × 2 days (days 1 and 2), then bid × 1 day (day 3), then QD (days 4-10)	10 days
DTPA (calcium and zinc)	Americium (Am-241) Californium (Cf-252) Cobalt (Co-60) Curium (Cm-244) Plutonium (Pu-238 and Pu-239) Yttrium (Y-90)	Chelating agent	IV (give once daily as a bolus or as a single infusion; i.e., do not fractionate the dose)	*Adults:* 1 g in 5 ml 5% D5W or 0.9% NS slow IV push over 3-4 min or 1 g in 100-250 ml D5W or NS as an infusion over 30 min *Children <12 yr:* 14 mg/kg/day slow IV push over 3-4 min (not to exceed 1 g/day)	• Begin treatment with Ca-DTPA, then change to Zn-DTPA for maintenance, as indicated • Duration of therapy depends on total body burden and response to treatment
			Nebulized inhalation (for use in adults only)	1 g in 1:1 dilution with sterile water or NS over 15-20 min	
			Wound irrigation fluid	1 g Ca- or Zn-DTPA and 10 ml 2% lidocaine in 100 ml 5% D5W or 0.9% NS	• Irrigation can be accompanied by IV or inhaled DTPA • Amount of DTPA absorbed by wound tissues cannot be measured • Avoid overdosing with DTPA and/or 2% lidocaine
EDTA	Cobalt (Co-60)	Chelating agent	IV	1000 mg/m^2 /day in 500 ml 5% D5W or 0.9% NS; infuse over 8-12 hr	Given as a single dose
			IM	Divide IV dose equally into two doses and administer 8-12 hr apart	Given as a divided dose
D-penicillamine	Polonium (Po-210)	Chelating agent	PO	*Adults:* 0.75-1.5 g (250 mg/capsule) QD *Children:* 30 mg/kg/day (250 mg/capsule) divided into 4 doses	• Obtain bioassay to assess • Continue only if clinically indicated • D-penicillamine has a narrow therapeutic index; use is associated with high risk of toxicity

TABLE E4 Radiation Countermeasures for Treatment of Internal Contamination—cont'd

Medical Countermeasure	Administered for	Mechanism of Action	Route of Administration	Dosage	Duration of Treatment
Potassium iodide (KI)	Iodine (I-131)	Blocking agent	PO	*Adults >40 yr:* 130 mg/day (for projected thyroid dose ≥500 cGy) *Adults 18-40 yr:* 130 mg/day (projected thyroid dose ≥10 cGy) *Pregnant or lactating women of any age:* 130 mg/day (for projected thyroid dose ≥5 cGy) *Adolescents ≥70 kg:* 130 mg/day (for projected thyroid dose ≥5 cGy) *Children & adolescents 3-18 yr:* 65 mg/day (projected thyroid dose ≥5 cGy) *Infants & toddlers 1 mo-3 yr:* 32.5 mg/day (projected thyroid dose ≥5 cGy) *Neonates from birth to 1 mo:* 16 mg/day (projected thyroid dose ≥5 cGy)	• Some incidents will require only a single dose of KI • Incident managers may recommend additional daily doses if ongoing radioactive iodine ingestion or inhalation represents a continuing threat
Potassium phosphate	Phosphorus (P-32)	Phosphate binder	PO	600-1200 mg, given in divided doses	
Potassium phosphate, dibasic	Phosphorus (P-32)	Phosphate binder	PO (take with full glass of water with meals and at bedtime)	*Adults:* 1-2 tablets (250 mg/tab) qid *Children >4 yr:* 1 tablet (250 mg/tab) qid	
Propylthiouracil	Iodine (I-131)	Blocking agent	PO	*Adults:* 2 tablets (50 mg/tab) tid	8 days
Prussian blue, insoluble	Cesium (Cs-137)	Ion exchange; inhibits enterohepatic recirculation in GI tract	PO	*Adults, children >12 yr:* • 1-3 g (2-6 capsules; 0.5 g insoluble Prussian blue per cap) tid; up to 10-12 g/day (based on Goiânia incident data) • 3 g (6 capsules; 0.5 g insoluble Prussian blue per cap) tid (see FDA package insert) • *Children 2-12 yr:* 1 g (2 capsules; 0.5 g insoluble Prussian blue per cap) tid • Capsules may be opened and contents mixed with food • See FDA package insert for pediatric prescribing information • *Children <2 yr:* Prussian blue is not FDA-approved for use (IND or EUA may be required)	• Minimum 30 day course per FDA • Obtain bioassay and whole-body count to assess treatment of efficacy • Duration of therapy depends on total body burden and response to treatment
Sevelamer	Phosphorus (P-32)	Phosphate binder	PO	• 2-4 tablets (400 mg-800 mg/tab) tid • Not to exceed 1600 mg tid	5 days if possible; first dose is the most important
Sodium alginate	Radium (Ra-226) Strontium (Sr-90)	Blocks intestinal absorption	PO (take with a full glass of water)	5 g bid × 1 day, then 1 g qid	
Sodium bicarbonate	Uranium (U-235)	Facilitates increased renal excretion	IV	• 2 amps (44.3 mEq bicarbonate/amp) in 1000 ml 5% D5W or 0.9% NS • 250 ml (1-2 mEq/kg) slow infusion	Administer therapy until urine pH is 8-9; continue for 3 days
			PO	2 tablets/q4h	
Sodium glycerophosphate	Phosphorus (P-32)		PO	600-1200 mg, given in divided doses	
Sodium phosphate	Phosphorus (P-32)		PO	600-1200 mg, given in divided doses	
SumLimer (DMSA)	Polonium (Po-210)	Chelating agent	PO	• 100 mg capsules • Administer 10 mg/kg or 350 mg/m^2 every 8 hr for 5 days, then reduce; safety and efficacy in children <12 yr has not been established	Reduce frequency of administration to 10 mg/kg or 350 mg/m^2 every 12 hr for an additional 2 wk of therapy; typical treatment course 19 days
Water	Tritium (H-3)	Facilitates excretion	PO	>3-4 L/day	3 wk

bid, Twice daily; *EUA,* emergency use authorization; *FDA,* Food and Drug Administration; *IND,* investigational new drug; *IV,* intravenous; *PO,* by mouth; *qid,* four times daily; *tid,* three times daily.

BASIC INFORMATION

DEFINITION

Ramsay Hunt syndrome is a localized herpes zoster infection involving the seventh nerve and geniculate ganglia, resulting in hearing loss, vertigo, and facial nerve palsy.

SYNONYMS

Herpes zoster oticus
Geniculate herpes
Herpetic geniculate ganglionitis

ICD-10CM CODE
B02.21 Postherpetic geniculate ganglionitis

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT SEX: Equal sex distribution
PREDOMINANT AGE:
- Increasingly common with advancing age
- Rare in childhood

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Characteristic vesicles:
  1. On pinna
  2. In external auditory canal (Fig. E1)
  3. In distribution of the facial nerve (VII cranial nerve) and, occasionally, adjacent cranial nerves can also be involved, such as V, IX, X
- Facial paralysis on the involved side
- Auditory symptoms include mild to severe tinnitus, deafness, vertigo, and nystagmus

FIG. E1 Herpes zoster of the geniculate ganglion resulting in vesicles on the ear (as shown here) and tympanic membrane occurs in Ramsay Hunt syndrome. Both seventh and eighth cranial nerve functions may be affected. (From White GM, Cox NH [eds]: *Diseases of the skin: color atlas and text,* ed 2, St Louis, 2006, Mosby.)

ETIOLOGY

- Reactivation of dormant infection with varicella-zoster virus after primary varicella.
- Herpetic inflammation of the geniculate ganglion is thought to be the cause of this syndrome.

DIAGNOSIS

- Usually made by recognition of the clinical features detailed previously
- Viral culture and/or microscopic examination of specimens taken from active vesicles

DIFFERENTIAL DIAGNOSIS

- Herpes simplex
- External otitis
- Impetigo
- Enteroviral infection
- Guillain-Barre syndrome
- Bell palsy of other etiologies, such as Lyme disease
- Acoustic neuroma (before appearance of skin lesions)

The differential diagnosis of headache and facial pain is described in Section II.

WORKUP

If the diagnosis is in doubt, confirm varicella-zoster virus infection.

LABORATORY TESTS

- Generally not necessary
- Viral culture of specimens of vesicular fluid and scrapings of the vesicle base
- Tzanck preparation, which may reveal multinucleated giant cells but has low sensitivity
- Direct immunofluorescent staining of scrapings

IMAGING STUDIES

MRI may demonstrate enhancement of the facial and vestibulocochlear nerves before appearance of vesicles.

TREATMENT

ACUTE GENERAL Rx

- Use of corticosteroids is controversial.
- Acyclovir (800 mg PO 5× qd for 10 days), famciclovir (500 mg tid for 7 days), or valacyclovir (1 g q8h for 7 days) may hasten healing.
- Use of prednisone (60 mg PO qd for 7 days or on a tapering regimen, 40 mg PO for 2 days, 30 mg for 7 days, followed by tapering course) is recommended by some authors, but its use remains controversial.
- Analgesics should be used as indicated.

CHRONIC Rx

- Duloxetine and amitriptyline are effective in postherpetic pain.
- Other agents for postherpetic pain include gabapentin and pregabalin.
- Narcotic analgesics may occasionally be necessary.

DISPOSITION

Recurrences are unusual.

REFERRAL

To otolaryngologist: Patients with persistent facial paralysis for potential surgical decompression of the facial nerve

PEARLS & CONSIDERATIONS

To prevent reactivation of herpes zoster, the herpes zoster vaccine is recommended. The Zoster Vaccine Recombinant, Adjuvanted (SHINGRX) is 90% effective after 2 doses and can be given to persons >50 yr of age.

COMMENTS

Immunodeficiency states, particularly HIV infection, should be considered in:
- Younger patients
- Severe cases
- Patients with a history of specific risk behavior

Raynaud Phenomenon PTG

BASIC INFORMATION

DEFINITION

Raynaud phenomenon (RP) is a vasospastic disorder that causes an exaggerated response to cold temperatures and/or emotional stress, resulting in episodic digital ischemia. It presents as a cold-induced, symmetric, sharply demarcated white or blue discoloration of the distal fingers or toes, followed by erythema at a variable time after rewarming.

SYNONYMS

Primary Raynaud phenomenon or Raynaud disease
Secondary Raynaud phenomenon
RP

ICD-10CM CODES

I73.0 Raynaud syndrome
I73.00 Raynaud syndrome without gangrene
I73.01 Raynaud syndrome with gangrene

EPIDEMIOLOGY & DEMOGRAPHICS

- RP is classified clinically into primary or secondary forms and affects approximately 3% to 5% of the general population, 15% of children younger than 12 yr, and less than 1% of adults older than 60 yr.
- Occurs more commonly in colder climates.
- Primary RP usually occurs between the ages of 12 and 25 yr.
- It is more likely to affect more women than men (4:1).
- 5% to 15% of patients with primary Raynaud phenomenon develop a secondary cause later in the course of the disease (mostly a connective tissue disorder).
- Secondary RP tends to begin after age 35 to 40 yr.
- Secondary RP occurs in more than 90% of patients with scleroderma and in approximately 30% of patients with systemic lupus erythematosus or Sjögren syndrome.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The typical manifestation of RP is the biphasic color response of the digits to cold exposure and rewarming, which may or may not be accompanied by pain. RP most often affects the hand (Fig. E1).
  1. White (pallor) or blue (cyanotic) discoloration of the digit(s) resulting from vasospasm on cold or vibration exposure.
  2. Red (rubor) with or without pain and paresthesia when vasospasm resolves and blood returns to the digit.
- Color changes can sometimes be induced by placing the hand in an ice bath, although this is not recommended as a diagnostic maneuver because responses may be inconsistent even in patients with definite RP.
- Color changes are well delineated, symmetric, and usually bilateral, involving the fingers and toes. The index, middle, and ring fingers are commonly involved and the thumb infrequently; however, if the thumb is involved, that suggests secondary causes of RP.
- Fingertips are most often involved, but feet, ears, nose, tongue, and nipples can also be affected.
- Patients with RP may exhibit a violaceous or reticular pattern of skin of arms and legs, sometimes with regular, unbroken circles (livedo reticularis).
- Duration of attacks can range from seconds to hours and averages 15 to 20 min.
- Chronic skin changes resulting from repeated attacks may include skin thickening and brittle nails. Ulcerations and, rarely, gangrene may occur.
- Physical examination should also include examination for symptoms associated with autoimmune disease, such as fever, rash, arthritis, dry eyes, dry mouth, myalgias, or cardiopulmonary abnormalities.

ETIOLOGY

- Primary RP can also be called idiopathic Raynaud phenomenon, primary Raynaud syndrome, or Raynaud disease. It occurs in the absence of any associated disease.
- With primary RP, the possibility that another first-degree family member is affected is reported as approximately 25%.
- Secondary RP is associated with an underlying pathologic condition or disorder, use of certain drugs, or related occupation. Secondary causes of Raynaud phenomenon are summarized in Box 1.

DIAGNOSIS

Clinical criteria:

- Definite RP: Repeated episodes of biphasic color change on cold exposure
- Possible RP: Uniphasic color changes plus numbness or paresthesia on cold exposure
- No RP: No color change on cold exposure

The suggested criteria for primary RP are:

- Symmetric attacks
- Absence of tissue necrosis, ulceration, gangrene, or peripheral vascular disease
- Absence of a secondary cause on the basis of a patient's history and general physical examination
- Negative nail-fold capillary examination
- Negative test for antinuclear antibody (ANA)
- Normal erythrocyte sedimentation rate (ESR)

Secondary RP is suggested by the following findings:

- Onset of symptoms after age 30 yr
- Male gender
- Episodes that are painful, asymmetric, or associated with ischemic skin lesions
- Clinical features suggestive of a connective-tissue disease
- Elevated specific autoantibody tests and ESR
- Evidence of microvascular disease on microscopy of nail-fold capillaries
- It is critical to differentiate primary and secondary RP since management is significantly different for the two conditions. Table 1 summarizes characteristics of primary and secondary Raynaud phenomenon

BOX 1 Secondary Causes of Raynaud Phenomenon

Rheumatologic
Systemic sclerosis (CREST syndrome)
Sjogren syndrome
Systemic lupus erythematosus
Ehlers-Danlos syndrome
Rheumatoid arthritis
Dermatomyositis
Polymyositis
Mixed connective tissue disease

Autoimmune
Reiter syndrome
Vasculitis (polyarteritis nodosa, Henoch-Schönlein purpura)
Antiphospholipid syndrome
Primary pulmonary hypertension

Endocrine
Hypothyroidism
Pheochromocytoma
Carcinoid

Infectious
Hepatitis B and C infection
Mycoplasma pneumonia

Medications
Cyclosporine
Ergotamine
Beta-blockers
Cytotoxic (bleomycin, cisplatin, vinblastine)
Bromocriptine
Nicotine
Cocaine
Sulfasalazine
Interferon-alpha and interferon-beta
Clonidine
Sympathomimetics
Estrogen in oral contraceptives
Caffeine

Occlusive Vascular
Arteriosclerosis
Vascular trauma (hypothenar hammer syndrome)
Buerger disease
Thoracic outlet syndrome
Thromboembolism

Hematologic Proliferative
Leukemia
Lymphoma
Polycythemia vera
Multiple myeloma
Disseminated intravascular coagulation
Cryoglobulinemia
Cold agglutinin disease

Neurologic
Migraines
Carpal tunnel syndrome
Polyneuropathy

Environmental
Emotional stress
Frostbite
Repetitive trauma or injuries to hand

Malignancy
Lung, stomach, small bowel
Paraneoplastic syndrome
Neurofibromatosis

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

TABLE 1 Characteristics of Primary and Secondary Raynaud Phenomenon

Characteristic	Primary	Secondary
Age	Younger (<30 yr)	Older (>30 yr)
Gender preference	Female	Male (depending on secondary cause)
Incidence	Most common	Less common
Familial predisposition	Yes	Yes
Combination with other disease	No, idiopathic	Associated with systemic disease
Vascular defect	Functional dysregulation of autonomic nervous system	Structural changes in connective tissue or vessels
Associated signs	None	Arthritis, sclerodactyly, cardiopulmonary abnormality, rash
Frequency	Precipitated by stimuli	Periodic and stimuli trigger
Severity of symptoms	Long history of mild attacks	Severe and disabling pain
Distribution	Symmetric	Asymmetric
Duration	Self-limited	Need for additional treatment (pharmacologic, surgery)
Critical complications	None	Ischemia and ulcers
Capillaroscopy	Normal (symmetric, thin, and uniform)	Abnormal (dilated, irregular, elongated, and tortuous vessel)
Vascular examination	Normal pulses	Abnormal pulses
Erythrocyte sedimentation rate	Normal	Elevated
Serologic studies	Negative	Antinuclear antibody, autoantibodies
C-reactive protein	Normal	Elevated

From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.

DIFFERENTIAL DIAGNOSIS

- Neurogenic thoracic outlet syndrome or carpal tunnel syndrome
- Frostbite or cold weather injury
- Medication reaction (ergotamine, chemotherapeutic agents)
- Atherosclerosis, thromboembolic disease
- Buerger disease, embolic disease
- Acrocyanosis
- Livedo reticularis
- Injury from repetitive motion

WORKUP

- Once the diagnosis of RP is established, differentiating primary from secondary is helpful in treatment and prognosis.
- Patients who are younger when their symptoms occur, have a normal history and physical examination and normal nail-fold capillaries, and have no history of digital ischemic lesions can be considered as having primary RP. These patients can be monitored clinically without any further testing.
- If a secondary cause of RP is suspected, appropriate laboratory testing is recommended (see "Laboratory Tests"). Secondary RP has associated abnormal nail-fold microscopy.

LABORATORY TESTS

- CBC, serum electrolytes, blood urea nitrogen, creatinine, ESR, ANAs, VDRL antibody test, rheumatoid factor, and urinalysis should be included in the initial evaluation.
- If the history, physical examination, and initial laboratory tests suggest a possible secondary cause, specific serologic testing (e.g., anticentromere antibodies, anti-Scl 70, cryoglobulins, complement testing, and serum protein electrophoresis) may be indicated.
- Noninvasive vascular testing includes finger systolic blood pressures, segmental blood pressure measurements, cold recovery time (measure vasoconstrictor and vasodilator responses of finger to cold), fingertip thermography, and laser Doppler with thermal challenge (measures relative change in skin blood flow with ambient warming).

IMAGING STUDIES

- The diagnosis of RP should not be made on the basis of laboratory tests, and imaging studies should not replace a good history and physical examination.
- Duplex ultrasound can image the palmar arch and digital arteries for patency.
- Magnetic resonance angiography is useful for imaging larger arteries.
- Contrast angiography is the gold standard for arterial imaging.
- Nail-fold capillary microscopy can differentiate primary from secondary RP.
- Videomicroscopy and thermography are also useful for diagnosis of RP.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid drugs that may precipitate RP (see "Etiology").
- Avoid cold exposure and sudden temperature shifts. Use warm gloves, hats, and garments during the winter months or before going into cold environments (e.g., air-conditioned rooms).
- Avoid stressful situations, and use relaxation techniques in preventing RP attacks.

ACUTE GENERAL Rx

- Acute measures to terminate an attack include rotating the arms in a windmill pattern, placing the hands under warm water or in a warm body fold such as the axilla, and the swing-arm maneuver.
- Medications are indicated in the treatment of RP if there are signs of critical ischemia or if the quality of life of the patient is affected to the degree that activities of normal living are no longer possible and preventive techniques do not work. Table 2 summarizes drugs commonly used in Raynaud phenomenon.

CHRONIC Rx

- Dihydropyridine calcium channel blockers (e.g., nifedipine, amlodipine, felodipine, nisoldipine, isradipine) are the most effective pharmacologic treatment for RP and are the drugs of choice. Amlodipine or nifedipine are commonly used.
- Amlodipine dosage ranges from 2.5 to 10 mg/day. Nifedipine is most often prescribed at a dose of 10 to 20 mg 30 min before cold exposure. If symptoms occur with long duration, nifedipine XL 30 to 180 mg PO qd is often effective.
- When calcium channel blockers do not appropriately control symptoms, phosphodiesterase inhibitors (cilostazol, pentoxifylline, and sildenafil) can be added or substituted. Sildenafil can be started at a dosage of 20 mg/day. Angiotensin 2 receptor antagonists (losartan), and selective serotonin reuptake inhibitors (fluoxetine) have also been used with some limited success.
- Some potential therapeutic options include direct vasodilators such as nitroprusside, hydralazine, papaverine, minoxidil, niacin, and griseofulvin. Topical 1% nitroglycerin or topical l-arginine, ethyl nicotinate, hexyl nicotinate, thurfyl salicylate may also be useful, particularly if low blood pressure is a concern.
- Alpha receptor antagonists such as prazosin and phenoxybenzamine have also shown some effectiveness in treating RP.
- The prostaglandins, including inhaled iloprost, IV epoprostenol, alprostadil, and tadalafil, may be promising in severe RP. However, additional experience and controlled studies are needed.
- Antioxidants like zinc gluconate have been used to decrease tissue damage.
- *N*-Acetylcysteine and probucol have been shown to lead to improvement in RP.
- Anticoagulation with IV unfractionated heparin or subcutaneous low-molecular-weight heparin and addition of aspirin can be considered during the acute phase of a severe ischemic event. Aspirin (81 mg/day) therapy can be considered in all patients with secondary RP with a history of ischemic ulcers or thrombotic events; however, caution should be exercised because aspirin can theoretically worsen vasospasm by the inhibition

TABLE 2 Drugs Commonly Used in Raynaud Phenomenon

Drug	Dosage
Oral	
Nifedipine (or other long-acting calcium channel blocker)	10-20 mg bid or tid
Sildenafil	25-50 mg tid
Naftidrofuryl oxalate	100-200 mg tid
Inositol nicotinate	1 g tid or inositol nicotinate forte 1.5 g bid
Thymoxamine	40-80 mg qid (stop after 2wk if no response)
Intravenous Infusion	
Iloprost	Start infusion (peripheral line) at 1 μg/hr; increase by 1 μg every 30 min until reach maximum tolerable dose (maximum dose should not be greater than 3 μg/hr). Infusions are given over 6 hr each day for 3-7 days on each occasion.
Prostaglandin E_1	60 μg in 250-ml physiologic infusion over 3 hr daily for 5-6 days. This could be repeated every 6 wk to cover the cold weather in severe cases, especially if associated with critical ischemia or digital ulceration, and should be given via a central line.

bid, Twice a day; *qid,* four times a day; *tid,* three times a day.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BOX 2 Features Suggestive of Progression of RP

Clinical
- Older age at onset (>35 yr)
- Recurrence of chilblains as adult
- Vasospasm all yr round
- Asymmetric attacks
- Sclerodactyly or any other sign of CTD
- Digital ulceration
- Finger pulp pitting scars

Laboratory
- Increased inflammatory markers
- Detection of autoantibodies
- Increased von Willebrand factor antigen

Nail-fold Microscopy
- Abnormal vessels on videomicroscopy

CTD, Connective tissue disorder.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

of prostacyclin. Long-term anticoagulation with heparin or warfarin is not recommended unless there is evidence of a hypercoagulable state.
- Bypass surgery can be performed for severe RP associated with reconstructible arterial occlusive disease.
- Sympathectomy is available for unreconstructible occlusive disease or pure vasospastic disease refractory to medical treatment.
- Microsurgical revascularization of the hand and digital reconstruction may improve digital vascular perfusion and heal digital ulcers when proximal arterial occlusion is associated with digital vasospasm.
- Ischemic digital lesions should be treated with topical antibiotics and daily cleansing with soap and water. Digits that progress to dry gangrene should be permitted to undergo autoamputation. Surgical amputation is limited for intractable pain or deep tissue infection.

DISPOSITION

The prognosis of patients with RP depends on the etiology.
- Primary RP is fairly benign, usually remaining stable and controlled with nonpharmacologic medical treatment.
- Remission of primary RP can occur spontaneously.
- Patients with secondary RP, specifically those with scleroderma, CREST syndrome, or thromboangiitis obliterans, may develop severe ischemic digits with ulceration, gangrene, and autoamputation.
- Box 2 summarizes features suggestive of progression of Raynaud phenomenon.

REFERRAL

- Rheumatology consult is indicated if secondary collagen vascular disease is diagnosed.
- Vascular surgery consult is indicated if ulcers, gangrene, or threatened digit loss is noted.

PEARLS & CONSIDERATIONS

- Most patients with RP can be managed by a primary care provider
- It is important to differentiate primary from secondary forms. Secondary forms may become manifest as far out as 10 yr from the diagnosis of RP. It is important to take immediate action during an attack, and patients are encouraged to:
  1. Keep warm
  2. Not use tobacco products
  3. Avoid aggravating medications
  4. Control stress
  5. Exercise
  6. Follow up with a physician

BASIC INFORMATION

DEFINITION

Reactive arthritis is one of the seronegative spondyloarthropathies, so called because serum rheumatoid factor is not present in these forms of inflammatory arthritis. Its characteristic clinical course consists of urethritis, conjunctivitis, and arthritis. Hans Reiter was a Nazi war criminal and many believe that he should no longer be given name recognition to designate this syndrome. Reactive arthritis is an asymmetric polyarthritis that affects mainly the lower extremities and is associated with one or more of the following:

- Urethritis
- Cervicitis
- Dysentery
- Inflammatory eye disease
- Mucocutaneous lesions

SYNONYMS

Reiter disease
Reiter syndrome
Seronegative spondyloarthropathy

ICD-10CM CODE
M02.30 Reiter disease, unspecified site

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 0.0035% annually of men ≤50 yr
PEAK INCIDENCE: Most common in the third decade
PREDOMINANT SEX: Male
PREDOMINANT AGE: 20 to 40 yr
GENETICS: Familial disposition: Strongly associated with HLA-B27 (63% to 96%)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Polyarthritis:
  1. Affecting the knee and ankle
  2. Commonly asymmetric
- Heel pain and Achilles tendinitis, especially at the insertion of the Achilles tendon
- Plantar fasciitis
- Large effusions
- Dactylitis, or "sausage toe"
- Urethritis
- Uveitis or conjunctivitis; uveitis can progress to blindness without treatment
- Keratoderma blennorrhagicum, circinate balanitis:
  1. Hyperkeratotic lesions on soles of the feet (Fig. E1), toes, penis (Fig. E2), hands
  2. Closely resembles psoriasis
- Aortic regurgitation similar to that seen in ankylosing spondylitis

ETIOLOGY

- Epidemic Reiter syndrome after outbreaks of dysentery has been well described.
- Genetically susceptible HLA-B27 individuals are at risk for developing reactive arthritis after infection with certain pathogens:
  1. *Salmonella*
  2. *Shigella*
  3. *Yersinia enterocolitica*
  4. *Chlamydia trachomatis*
- Symptom complex indistinguishable from reactive arthritis has been described in association with HIV infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ankylosing spondylitis
- Psoriatic arthritis
- Rheumatoid arthritis
- Gonococcal arthritis-tenosynovitis
- Rheumatic fever
- Serum sickness
- Gout
- Chronic mucocutaneous candidiasis

WORKUP

- X-ray examination of affected joints
- Synovial fluid examination and culture
- Careful examination of eyes and skin
- Cultures for gonococcus (urethral, cervical, stool)

LABORATORY TESTS

- Elevated but nonspecific erythrocyte sedimentation rate
- No specific laboratory tests to diagnose reactive arthritis
- Do not use HLA-B27 testing as a diagnostic tool, as only positive in 30% to 50% of patients

IMAGING STUDIES

Plain radiographs:

- Juxtaarticular osteopenia of affected joints
- Erosions and joint space narrowing in more advanced disease
- Periostitis and reactive new bone formation at the insertions of the Achilles tendon and the plantar fascia
- Sacroiliitis:
  1. Unilateral or bilateral
  2. Indistinguishable from ankylosing spondylitis
- Vertebral bridging osteophytes

TREATMENT

NONPHARMACOLOGIC THERAPY

Physical therapy to maintain range of motion of the spine and other joints

ACUTE GENERAL Rx

- Flares treated with nonsteroidal antiinflammatory drugs such as indomethacin (25 to 50 mg PO tid). Refractory cases can be treated with methotrexate or infliximab.
- Mucocutaneous lesions are visually self-limited and clear with topical corticosteroids. Acitretin or cyclosporine can be used for refractory skin lesions.
- Enteric or urethral infection should be treated with appropriate antibiotic coverage.
- Uveitis should be treated with steroid eye drops in consultation with an ophthalmologist.
- Achilles tendinitis and plantar fasciitis should be treated with injections of methylprednisolone (40 to 80 mg).
- Sulfasalazine (500 to 1000 mg PO bid, then titrate up to maximum 3 g/day) may be effective.
- Careful monitoring for the following is essential:
  1. Gastrointestinal toxicity
  2. Hypersensitivity
  3. Bone marrow suppression
- Persistent and uncontrolled disease should be managed with cytotoxic drugs (methotrexate, azathioprine) in consultation with a rheumatologist.
- The role of tumor necrosis factor alpha inhibitors in therapy is evolving, but agents such as etanercept for 6 mo or infliximab have been shown to be helpful in small studies.

CHRONIC Rx

Chronic disease is best managed by a team approach with the collaboration of a rheumatologist or other experienced physician and physical therapist.

DISPOSITION

- Recurrences are frequent, even with treatment.
- Long-term sequelae:
  1. Persistent polyarthritis
  2. Chronic back pain
  3. Heel pain
  4. Progressive iridocyclitis
  5. Aortic regurgitation

REFERRAL

- To ophthalmologist if uveitis is suspected
- To rheumatologist if arthritis and tendinitis fail to improve rapidly after a course of nonsteroidal antiinflammatory drugs

PEARLS & CONSIDERATIONS

COMMENTS

- Infection with HIV is associated with particularly severe cases of reactive arthritis.
- HIV testing is recommended, especially if risk factors such as unprotected sexual activity or IV drug use are identified.
- The role of antibiotics seems useful in *Chlamydia*-triggered arthritis, but the role of antibiotics in arthritis triggered by enteric pathogens is less clear.

Rectal Prolapse

BASIC INFORMATION

DEFINITION

Rectal prolapse is an often socially disabling condition characterized by the circumferential protrusion of part or all layers of the rectum beyond the anus. The two main types of rectal prolapse include: (1) Partial prolapse including the anal or rectal mucosa only, and (2) complete (full-thickness) prolapse involving all layers of the rectum (Fig. E1). A third and less common type is prolapse of the rectal wall that does not protrude through the anus, known as an occult prolapse or rectal intussusception.

SYNONYMS

Procidentia
Rectal intussusception

ICD-10CM CODES

K62.3	Rectal prolapse
K62.2	Anal prolapse

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown in general population. In children with cystic fibrosis it approaches 20%.
PEAK INCIDENCE: Women after the fifth decade represent between 80% and 90% of patients with rectal prolapse. Incidence increases with each decade in female patients until the seventh decade.
PREVALENCE: N/A
PREDOMINANT SEX AND AGE: Rectal prolapse occurs at the extremes of age, with an equal sex distribution in children. In adults, females predominate by a ratio of nine to one.
GENETICS: N/A
RISK FACTORS: Cystic fibrosis, hemorrhoids, laxity of the pelvic fascia/muscles due to prior pelvic surgery or obstetric trauma, anal sphincter dysfunction, chronic constipation, and increasing age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most patients detect a mass, usually after defecation or strenuous activity. Later in the course, patients may develop prolapse with activities such as standing or walking.
- In children, the prolapse usually appears as a painless, maroon-colored mass associated with mucus or blood.
- Anal sphincter weakness associated with rectal prolapse may cause fecal incontinence
- Other common symptoms include rectal bleeding, a change in bowel habits, incomplete evacuation or tenesmus, and a mucus-like discharge with bowel movements.
- Differentiating between mucosal and complete prolapse can be helpful yet challenging. Mucosal prolapse usually occurs distal to the dentate line, extending only a few centimeters beyond the anus. Complete prolapse may extend up to 15 cm and will usually have a normal-appearing anus as compared with mucosal prolapse, in which the anal edges appear everted.

ETIOLOGY

- Rectal prolapse is associated with chronic straining, leading to pelvic muscle and nerve dysfunction or weakness.
- Multiple conflicting theories exist for the etiology of rectal prolapse including: (1) A redundant sigmoid colon lying deep within the pelvis, (2) an intussusception due to poor anorectal tone, (3) injury to the pudendal nerves from repeated stretching of the pelvic floor, and (4) abnormal fixation of the rectum.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Rectal cancer, hemorrhoids, rectal polyps, intussusception

WORKUP

General principles of evaluation include a thorough physical examination including digital rectal examination, imaging studies to evaluate various etiologies, and colorectal surgical consultation for repair.

LABORATORY TESTS

- In general, patients with rectal prolapse do not need laboratory testing if they appear well or are mostly asymptomatic.
- A hemoglobin/hematocrit may be obtained if there is concern for significant bleeding. A metabolic panel may be obtained if there is concern for electrolyte abnormalities.
- All patients that require surgical intervention will need preoperative laboratory testing.

IMAGING STUDIES

- Screening evaluation of the colon with colonoscopy or a barium enema is recommended in most adult patients after reduction or repair of rectal prolapse.
- Additional studies such as cinedefecography, anorectal manometry, electromyography, and colonic transit studies may be considered in the evaluation of patients with rectal prolapse in consultation with a specialist.

TREATMENT

- Patients with a small rectal prolapse that reduces on its own may be managed conservatively with stool softeners. Early specialist referral is encouraged to exclude alternative diagnoses and for serial examinations.
- Operative intervention is the mainstay of treatment for rectal prolapse that requires manual reduction. Goals of surgical treatment include control of the prolapse, restoring continence, and preventing constipation.
- The choice of operative repair takes into account many factors, including coexisting slow transit constipation, postoperative rectal compliance, pelvic floor denervation, the possibility of postoperative sexual dysfunction in men, age, cardiac and pulmonary risk factors, prior abdominal surgeries or pelvic irradiation, and overall immune function.
- Given that many patients with rectal prolapse carry high operative risk due to age and concomitant disease, nonoperative treatment is appealing but only temporary.

NONPHARMACOLOGIC THERAPY

- Abdominal procedures such as suture rectopexy with sigmoid resection and/or subtotal colectomy yield better results in young, healthy patients and are associated with lower recurrence rates.
- Perineal procedures such as perineal rectosigmoidectomy with levatorplasty have a higher rate of recurrence and functional abnormality, yet carry a lower surgical risk and are thus reserved for high-risk, older surgical patients.

ACUTE GENERAL Rx

- Manual reduction can be attempted after appropriate analgesia or sedation. In children, the protruding mucosa proximal to the anorectal ring is replaced by applying slow and steady pressure to the prolapsed segment.
- In adults, manual reduction is more challenging and may take several minutes. The thumbs are placed over the prolapsed segment medially and the fingers grasp the outer walls laterally. Continuous, steady pressure starting with the thumbs followed by rolling of the fingers can aid in reduction.
- After reduction, a digital rectal examination should be performed on all patients to ensure that the reduction is complete, and to evaluate for mass or polyps. Gauze with a lubricant jelly can be placed over the anus and taped in place after reduction.
- Patients with severe rectal prolapse that cannot be reduced or have ischemia/gangrene of the prolapsed segment will require emergency surgical consultation and hospitalization.
- Granulated sugar applied for 15 min to a swollen prolapsed segment has been used to reduce edema before attempting manual reduction.

FIG. E1 Prolapse of the rectum. (Courtesy Gershon Effron, MD, Sinai Hospital of Baltimore. From Seidel HM et al: *Mosby's guide to physical examination,* ed 4, St Louis, 1999, Mosby.)

CHRONIC Rx

Patients with edematous rectal walls, venous engorgement, thrombosis, ulcerations, strangulation, or ischemia will likely not be candidates for manual reduction and will require more urgent surgical referral.

COMPLEMENTARY & ALTERNATIVE MEDICINE

N/A

DISPOSITION

- Patients with reducible and nonischemic rectal prolapse without significant bleeding can be referred for outpatient surgical consultation and intervention.
- Patients with ischemic or nonreducible segments associated with gangrene or severe bleeding will need to be hospitalized.

REFERRAL

Patients with rectal prolapse will require colorectal surgical consultation. Many patients will also require referral to a gastroenterologist for screening colonoscopy.

PEARLS & CONSIDERATIONS

COMMENTS

- Rectal prolapse is a relatively rare yet socially debilitating condition that appears at the extremes of age.
- Manual reduction is the mainstay of initial treatment after appropriate analgesia or sedation.
- Surgical referral is warranted for all patients and emergent referral should be made for all patients with ischemic, gangrene, or nonreducible prolapsed segments.

PREVENTION

Avoiding chronic constipation

AUTHOR: **Rory Merritt, MD, MEHP**

Relapsing Polychondritis

BASIC INFORMATION

DEFINITION

Relapsing polychondritis (RP) is a rare, progressive, autoimmune disorder characterized by episodic inflammation and destruction of cartilage and proteoglycan-rich tissues such as those present in the eyes, inner ear, cardiovascular system, and kidneys.

SYNONYMS

Chronic atrophic polychondritis
RPC
Generalized or systemic chondromalacia
Meyenburg-Altherr-Uehlinger syndrome
Relapsing perichondritis
von Meyenburg disease

ICD-10CM CODE
M94.1 Relapsing polychondritis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 3.5 cases per million. There is similar frequency of cases in both sexes. RP is associated with human leukocyte antigen-DR4. Box 1 summarizes conditions associated with relapsing polychondritis.
PREDOMINANT SEX: Males and females are affected equally.
PREDOMINANT AGE: Peak onset is between 40 and 60 yr, although RP has been described in children.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- RP affects cartilaginous and noncartilaginous structures.
- Acute unilateral or bilateral auricular chondritis affecting the pinna and sparing the earlobe (Fig. E1) is the classic clinical feature and the most common symptom. It presents with sudden onset of redness, swelling, warmth, and pain. RP may resolve with or without treatment in 5 to 10 days. Repeated attacks may progress to a pinna devoid of firmness and a cauliflower-like appearance. Swelling of the outer ear or inner ear artery vasculitis may cause deafness or vertigo.
- The second most common symptom is arthritis in an asymmetric pattern.
- RP may affect the nasal cartilage, causing saddle-nose deformity (Fig. E2), structures of the inner ear leading to auditory or vestibular complications, and ocular structures.
- Respiratory disease develops in 50% of patients and is noteworthy because of its association with lethal organ system involvement and worse prognosis. Patients may have symptoms such as hoarseness, aphonia, tenderness over the anterior neck (anterior trachea cartilage or thyroid cartilage [Fig. E3]), or persistent dry cough.
- Cardiovascular, ocular, renal, neurologic, and mucocutaneous manifestations are possible.
- Table 1 demonstrates frequency of initial findings at time of diagnosis with subsequent symptoms.
- Anemia at the time of diagnosis in individuals older than 50 may be a poor prognostic factor. Macrocytic anemia warrants suspicion of myelodysplasia.

ETIOLOGY

Unknown, felt to be an autoimmune condition. Some association with HLA-DR4 is seen.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection (tuberculosis, fungal disease, leprosy, syphilis)
- Leukemia cutis, lymphoma
- Red ear syndrome
- ANCA-associated vasculitides
- Cogan syndrome
- Chondrodermatitis nodularis helicis

1. Diagnosis is clinical, and McAdams criteria (Box 2) commonly are used. Presence of any three of the following is diagnostic: 1) bilateral auricular chondritis, 2) nonerosive inflammatory polyarthritis, 3) chondritis of nasal cartilage, 4) inflammation of ocular structures (conjunctivitis, keratitis, scleritis, episcleritis, uveitis), 5) chondritis of the respiratory tract (laryngeal/tracheal cartilage), 6) cochlear and/or vestibular damage (hearing loss, tinnitus, vertigo).
2. Since RP is a remittent and rare disease, diagnosis may be delayed.

LABORATORY TESTS

- No specific blood tests to diagnose RP.
- Acute-phase reactants may be elevated during times of disease activity.
- Serologic testing as warranted if associated condition such as rheumatoid arthritis or ANCA-associated vasculitis is suspected.
- Synovial fluid analysis if arthritis is present.
- Cartilage biopsy (Fig. E4).

IMAGING STUDIES

- Pulmonary function tests (PFTs) should be obtained in all suspected cases. If abnormal, chest CT is warranted to look for abnormalities such as airway stenoses or dynamic airway collapse. Expiratory CT abnormalities are common. Findings may be missed if not obtained during expiratory phase.
- Echocardiogram can be used to characterize cardiopulmonary symptoms and assess heart valves.
- PET/CT and MRI may be used to monitor disease activity and response to treatment.
- Biopsy, though not required, demonstrates cartilage with loss of basophilic staining of cartilage matrix, perichondrial inflammation, and potential cartilage destruction (see Fig. E3). Infiltrates are mainly plasma cells and lymphocytes.

BOX 1 Conditions Associated with Relapsing Polychondritis

- Rheumatoid arthritis
- Systemic lupus erythematosus
- Scleroderma
- Sjögren syndrome
- Overlap connective tissue disease
- Ankylosing spondylitis and sacroiliitis
- Psoriatic arthritis
- Reactive arthritis
- Antineutrophil cytoplasmic antibody-associated granulomatous vasculitis
- Polyarteritis nodosa
- Churg-Strauss vasculitis
- Behçet syndrome
- Myelodysplastic syndromes
- Lymphoma
- Inflammatory bowel disease
- Primary biliary cirrhosis

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

TABLE 1 Clinical Manifestations of Relapsing Polychondritis

Finding	Frequency (%) Initial	Total
Auricular chondritis	39	85
Saddle-nose deformity	18	29
Hearing loss	9	30
Arthritis	36	52
Costochondral cartilage inflammation	2	2
Nasal cartilage inflammation	24	54
Ocular inflammation	19	51
Scleritis or episcleritis	19	47
Laryngotracheal-bronchial disease	26	48
Laryngotracheal stricture	15	23
Systemic vasculitis	3	10
Valvular dysfunction	0	6
Cutaneous features	7	28

Adapted from Isaak BL, Liesegang TJ, Michet CJ Jr. Ocular and systemic findings in relapsing polychondritis, *Ophthalmology* 93:681-9, 1986. In Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BOX 2 Diagnostic Criteria for Relapsing Polychondritis

- Bilateral auricular chondritis
- Nonerosive seronegative inflammatory polyarthritis
- Nasal chondritis
- Ocular inflammation (conjunctivitis, keratitis, scleritis and/or episcleritis, uveitis)
- Respiratory tract chondritis (laryngeal and/or tracheal cartilages)
- Cochlear and/or vestibular dysfunction (neurosensory hearing loss, tinnitus, and/or vertigo)
- Cartilage biopsy confirmation of a compatible histologic picture

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Severe airway, cardiac, and sensorineural deficits require a holistic approach. Airway teams should be aware of pathologic airways. Tracheobronchomalacia may require tracheostomy, stenting of airway, or nighttime positive pressure ventilation. Cardiac intervention to treat aortic root dilation or valvular disease may be warranted. Cochlear implantation may restore hearing. Interventions ideally should take place during disease quiescence.

ACUTE GENERAL Rx

Initial management of patients with acute RP is dependent on severity. For minor inflammation (nose, ear, or chest wall), NSAIDs, low dose corticosteroids, colchicine, or dapsone may be used. Serious or life-threatening manifestations such as severe chondritis, laryngotracheal or ocular symptoms often require 1 mg/kg of prednisone with slow taper.

CHRONIC Rx

- Steroid dependence, relapses, or life-threatening manifestations may warrant disease modifying therapies. Case reports have demonstrated success with methotrexate, cyclophosphamide, mycophenolate mofetil, azathioprine, chlorambucil, cyclosporine, and IVIG.
- RP refractory to conventional treatments has been treated successfully with TNF inhibitors, tocilizumab, anakinra, and abatacept. Rituximab has more negative than positive case reports.

REFERRAL

- ENT for audiovestibular symptoms
- Pulmonology, anesthesia, and surgery for airway management
- Rheumatology

PEARLS & CONSIDERATIONS

- Prompt diagnosis is necessary to avoid severe complications.
- Respiratory involvement, number of manifestations, and anemia predict reduced survival.
- All patients should have airway and laryngotracheal involvement assessed through neck and chest x-rays and PFTs. Flow volume loops may reveal fixed extrathoracic obstruction.

Renal Abscess

BASIC INFORMATION

DEFINITION

Renal abscess and perinephric abscess are purulent complications of an underlying urinary infection of the ascending tract with an obstructed pyelonephritis. Predisposing factors include diabetes and renal stones. There is lobar necrosis with renal abscess and perirenal fat necrosis in perinephric abscess.

SYNONYMS

Intrarenal abscess
Perinephric abscess
Kidney abscess

ICD-10CM CODE
N15.1 Renal and perinephric abscess

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Ranges from 1 to 10 per 10,000 hospital admissions
PREDOMINANT SEX AND AGE: In one study median age was 59.8 yr
RISK FACTORS: Diabetes and renal stones

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms include fever, flank pain, abdominal pain, and urinary frequency or dysuria.
- At times renal abscess can present insidiously in the elderly or persons with diabetes.

ETIOLOGY

These infections may be a complication of a urinary tract infection that ascends to the upper tract, usually due to gram-negative bacteria, or a complication of a bacteremia with hematogenous seeding to the kidney, usually secondary to a *Staphylococcus aureus* infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute pyelonephritis with papillary necrosis
- Acute lobar nephronia: Acute nonsuppurative renal infection
- Renal cell carcinoma
- Malakoplakia: Rare granulomatous inflammatory disease seen with *Escherichia coli* infection
- Emphysematous pyelonephritis: Gas formation within the renal parenchyma caused by infection by facultative anaerobes or *Candida* spp.

WORKUP

Combination of laboratory tests and imaging

LABORATORY TESTS

- Blood cultures, urine cultures, urinalysis, and CBC are basic tests.
- Elevated ESR or C-reactive protein may be marker for a deep-seated infection.

IMAGING STUDIES

- Ultrasound may show thick-walled fluid-filled cavity in renal parenchyma. A perinephric abscess is confined to the perinephric space by Gerota fascia.
- CT with contrast (Fig. E1) is preferred over ultrasound for the diagnosis.
- MRI and nuclear scans are of limited value.

TREATMENT

Antibiotic therapy and, when necessary, interventional radiology or surgical drainage procedure

NONPHARMACOLOGIC THERAPY

- Therapy for a renal abscess greater than 5 cm in diameter should be percutaneous drainage by CT- or US-guided therapy along with intravenous antibiotics.
- A perinephric abscess should be drained percutaneously with CT or US guidance.
- At times a nephrectomy may be required for severe cases, usually in diabetic patients.

ACUTE GENERAL Rx

A renal abscess less than 5 cm in diameter can be treated successfully with targeted intravenous therapy (92% success rate for abscess 3 to 5 cm in diameter). Antibiotic choices are based on culture results but initially should target gram-negative bacteria unless infection is secondary to staphylococcal bacteremia. Empiric antibiotic therapy in geographic areas where fluoroquinolone resistance rates are <10% consists of ciprofloxacin 400 mg IV loading dose. In areas with high fluoroquinolone resistance rates, ceftriaxone 1 g IV is appropriate. If perinephric abscess is associated with staphylococcal bacteremia, give IV nafcillin if methicillin-susceptible *Staphylococcus aureus* (MSSA) or vancomycin 1 g IV q12h if methicillin-resistant *S. aureus*.

CHRONIC Rx

Antibiotic therapy generally continues for 2 to 3 weeks, some of which can be completed with oral therapy.

DISPOSITION

Antibiotics such as trimethoprim-sulfamethoxazole and quinolone antibiotics penetrate well in the kidney and are ideal oral agents for therapy.

REFERRAL

Interventional radiology, urologic surgeon, and infectious diseases consult

PEARLS & CONSIDERATIONS

COMMENTS

This diagnosis should be considered in patients who are being treated for pyelonephritis with appropriate antibiotics and fail to respond clinically after 5 days.

PREVENTION

Early and targeted therapy for urinary tract infections, especially in diabetic patients

BASIC INFORMATION

DEFINITION

Renal artery stenosis (RAS) is the progressive narrowing of the renal artery, which is most commonly due to atherosclerosis or fibromuscular dysplasia (FMD). RAS is an important, potentially reversible cause of hypertension, ischemic nephropathy, and destabilizing cardiac syndromes. RAS increases the risk of renal artery occlusion via progression of the severity of the stenosis.

SYNONYMS

Fibromuscular disease
FMD
RAS
Renovascular disease

ICD-10CM CODES

I70.1	Atherosclerosis of renal artery
I15.0	Renovascular hypertension
I77.9	Disorder of arteries and arterioles, unspecified
Q27.1	Congenital renal artery stenosis

EPIDEMIOLOGY & DEMOGRAPHICS

- RAS:
  1. Atherosclerotic RAS (ARAS) accounts for about 90% of cases. True prevalence is unknown.
     a. General population autopsy studies: 10%, 27% over 50 yr; hypertensive patients: 0.2% to 5%.
     b. In the general population >65 yr of age, the prevalence is 6.8% by Doppler ultrasound (5.5% of women, 9.1% of men, 6.7% of African Americans, and 6.9% of Caucasians). Of those with ARAS, 12% had bilateral disease.
     c. In patients with malignant hypertension, the prevalence is 43% in Caucasians and 7% in African Americans. In patients with mild hypertension, the prevalence is <1%.
     d. In patients with peripheral artery disease, the prevalence is 22% to 59%.
  2. FMD accounts for approximately 10% of chronic RAS. It is typically seen in women (90%). FMD was previously thought to be a disease of the young and healthy with few risk factors, but recent data suggest an average age of diagnosis of 54 yr, and 26% have bilateral disease.

ETIOLOGY

- Atherosclerosis: ARAS is a process similar to atherosclerosis in other vascular beds with similar risk factors: family history, smoking, diabetes, hypertension, and hyperlipidemia. ARAS most often involves the ostium and proximal third of the main renal artery.
- Fibromuscular dysplasia (FMD) (Figs 1 and 2): Etiology unknown. Classified into three categories based on the layer of arterial wall affected: medial (>90%), intimal (<10%), adventitial (<1%). FMD typically involves the distal main renal artery and intrarenal branches.

PATHOGENESIS

- Pathogenesis of fibromuscular dysplasia is unknown. Fibromuscular dysplasia involves abnormal constrictions and dilations of the renal artery, leading to a typical "string of beads" finding on angiography.
- The pathogenesis of atherosclerotic RAS is similar to that of atherosclerosis in other vascular beds.
- The pathogenesis of renovascular hypertension is related to the neurohormonal cascade resulting from renal ischemia. The macula densa of the kidney senses a decreased systemic blood pressure caused by the reduced blood flow through the stenotic artery. Renal hypoperfusion or ischemia produces an increase in plasma renin that converts angiotensin I to angiotensin II, producing vasoconstriction and aldosterone secretion, sodium retention, and potassium wasting. Hypertension results and can be self-sustaining, even in the case of unilateral RAS, because of hypertensive damage to the contralateral kidney.
- The pathogenesis of ischemic nephropathy is a topic of current debate. Whether renal dysfunction develops purely from persistent ischemia related to progressively narrowed vessels or from repetitive small ischemic insults and upregulation of inflammatory mediators is yet to be fully elucidated.
- "Flash" or sudden-onset pulmonary edema, a manifestation usually seen in bilateral ARAS, results from sodium and water retention as well as upregulation of the sympathetic nervous system.

NATURAL HISTORY

- RAS caused by fibromuscular dysplasia rarely causes renal artery occlusion or ischemic nephropathy.
- ARAS rarely progresses to total occlusion. One study of serial ultrasounds of patients with RAS demonstrated that those with >60% stenosis progressed to total occlusion in 1 yr in only 5% of cases; an additional 11% progressed after 2 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Progressive RAS:

- Renal artery stenosis should be considered in any white female aged <30 yr with hypertension not attributed to any other cause, or in any patient aged >50 yr with new-onset refractory hypertension, or with stable hypertension that has abruptly and significantly worsened.
- RAS most often presents as a clinically asymptomatic finding. Manifestations can include renovascular hypertension, ischemic nephropathy, or flash pulmonary edema.
- Flash pulmonary edema in the absence of cardiac disease most often indicates severe bilateral renal artery stenosis.
- Renovascular hypertension should be considered if blood pressure control remains suboptimal on a medication regimen that includes 3 maximally dosed medications, including a diuretic.
- Ischemic nephropathy should be considered if kidney function is rapidly deteriorating or parenchymal sizes are decreasing on serial imaging, particularly with bilateral disease.
- Acute elevation of serum creatinine (>30%) after starting angiotensin–converting-enzyme inhibitors (ACEIs) or angiotensin type I receptor blockers (ARBs) may be seen in bilateral disease.
- A bruit heard in either upper quadrant on abdominal auscultation may suggest RAS. Patients with atherosclerotic RAS will often have bruits heard in other vascular beds.

DIAGNOSIS

SCREENING

American College of Cardiology and American Heart Association (ACC/AHA) guidelines for identification of patients who should be screened for RAS:

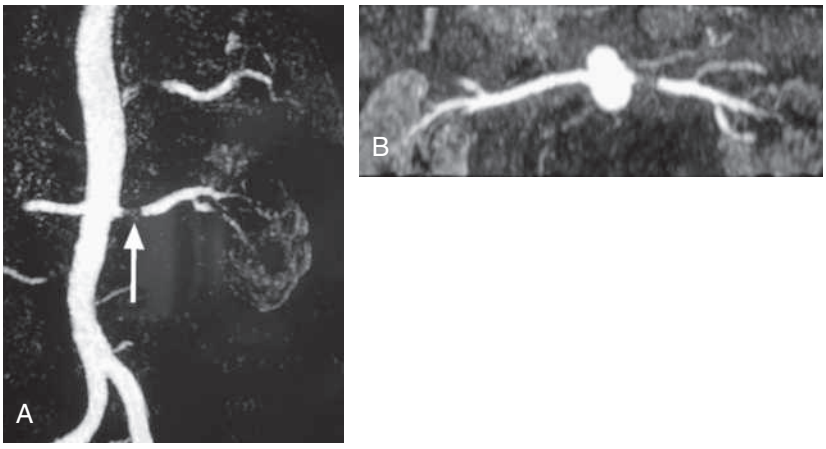

FIG 1. Magnetic resonance angiogram. **A,** Coronal maximum intensity projection (MIP) of a patient with significant left renal artery stenosis *(white arrow).* **B,** Axial MIP of the same patient. (From Adam A et al: *Grainger & Allison's diagnostic radiology,* ed 5, 2007, Churchill Livingstone. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

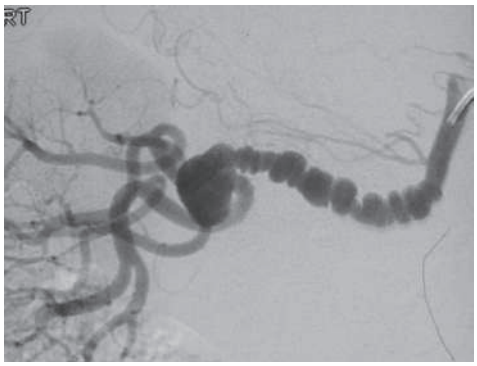

FIG. 2 Fibromuscular dysplasia. On a selective right anterior oblique (RAO) digital subtraction angiogram, the characteristic saccular dilatations and web-like stenoses are clearly evident. (From Adam A et al: *Grainger & Allison's diagnostic radiology,* ed 5, 2007, Churchill Livingstone. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

- Onset of hypertension at age <30 yr or severe hypertension at age >55 yr
- Clinical findings that suggest secondary hypertension as opposed to essential hypertension in the absence of a more likely cause of secondary hypertension such as pheochromocytoma
- Malignant hypertension: Hypertension with coexistent evidence of acute end-organ damage (acute renal failure, acute decompensated heart failure, new visual or neurologic disturbance, and/or advanced retinopathy)
- Accelerated hypertension: Sudden and persistent worsening of previously controlled hypertension
- Resistant hypertension: Full doses of a three-drug regimen that includes a diuretic
- Sudden unexplained pulmonary edema
- New azotemia or acute kidney injury following initiation of an ACEI or ARB
- Unexplained atrophic kidney or variation in size of both kidneys by >1.5 cm, smaller kidney likely affected by RAS
- Consider screening when renal asymmetry is noted with kidney lengths differing by ≥1.5 cm

LABORATORY TESTS

- Basic chemistry panel including sodium, potassium, blood urea nitrogen, and serum creatinine
- Urinalysis
- Renal vein renin sampling helps determine whether one or both kidneys are overproducing renin in cases of suspected renovascular hypertension (RVH). A positive result has strong predictive value. However, 50% of patients with no evidence for lateralization can still respond to unilateral intervention. This procedure is rarely performed except in specialized hypertension centers

IMAGING STUDIES

Renal Duplex Doppler ultrasonography, CT angiography, and magnetic resonance angiography (MRA) are effective diagnostic screening methods. The choice of imaging modality will depend on the availability of the diagnostic tool, the experience and local accuracy of each modality, patient characteristics including body size, renal function, and contrast allergy, and the presence of prior stents.

RENAL DOPPLER ULTRASOUND:

- Renal Doppler is a noninvasive, inexpensive screening study, and it can determine whether a stenosis of >60% is present.
- Abnormal results in RAS:
  1. Peak systolic velocity (PSV) >250 cm/sec
  2. Peak diastolic velocity >150 cm/sec
  3. Renal-to-aortic ratio (RAR) >3.5
  4. Acceleration time >100 msec
  5. Exact definitions of a positive renal Doppler for RAS will vary by institution
- Compared to renal angiography, Doppler studies have shown varied performance, with a sensitivity of 84% to 98% and a specificity of 62% to 99%.
- Limitations include high user variability. Valid test performance requires technicians who perform a high volume of these tests to reduce user error. If significant user variability exists at certain institutions, renal Doppler may be excluded from diagnostic algorithm. Patients with a large body habitus may have limited imaging results. It is not as sensitive or specific as MR or CT methods. Detection of RAS is limited to identifying whether stenosis of 60% to 99% is present.
- Duplex Doppler is a good modality for monitoring patency after a stent has been placed.

MAGNETIC RESONANCE ANGIOGRAPHY:

- MRA provides good visualization of both main and accessory renal arteries. The test has high sensitivity (90% to 100%) and a specificity of 76% to 94%. It is superior to renal Doppler ultrasonography and equivalent to CT angiography.
- Benefits include the lack of exposure to iodine contrast or radiation.
- Limitations include claustrophobia, high cost, and inability to image within a previously placed metallic stent. In addition, gadolinium exposure is relatively contraindicated in CKD patients with an estimated glomerular filtration rate (GFR) <30 ml/min per 1.73 m^2 due to the risk of inducing nephrogenic systemic fibrosis.

COMPUTED TOMOGRAPHY ANGIOGRAPHY:

- CT angiography is rapid and effective. When compared with angiography, CT has a sensitivity of 59% to 96% and a specificity of 82% to 99%. It is superior to renal Doppler and equivalent to MRA. Contrast uptake in kidneys can also be used to estimate viability of affected kidneys.
- CT has good spatial resolution and can detect restenosis through metal stents.
- CTA can be used more easily than MRA in obese or claustrophobic patients.
- Limitations include radiation exposure and potentially nephrotoxic, iodinated radiocontrast medium exposure to CKD patients. Heavily calcified arteries may appear narrower than in actuality.

DIRECT ANGIOGRAPHY:

- IV digital subtraction angiography (DSA) has an 88% sensitivity and 90% specificity. It is the gold standard for anatomic diagnosis of RAS. It is not a first-line screening tool, but it is recommended after a positive noninvasive test. DSA is also used for patients with a high clinical suspicion for RAS and inconclusive noninvasive tests and in whom the decision has already been made that correction of stenosis will produce clinical benefit. DSA allows for angioplasty with stenting during the same procedure. Renal fractional flow reserve at the time of DSA can evaluate the severity of RAS during maximal vasodilatation.
- This modality is reserved for patients with a high likelihood of intervention.
- Limitations include its invasive nature, requiring intraaortic catheterization that may lead to aortic and renal artery trauma with possible dissection, rupture, thrombosis, or embolization.
- Procedure requires a skilled interventionalist (radiologist, cardiologist, or vascular surgeon) knowledgeable in RAS.
- Procedure requires iodinated contrast and must be used cautiously with CKD. Carbon dioxide contrast imaging and limiting image acquisition number reduce kidney injury risk.

NUCLEAR RENOGRAPHY (WITHOUT CAPTOPRIL): A noninvasive test conducted when renal atrophy is present to document differential kidney function. This can be useful when determining whether to revascularize an atrophic kidney or to remove it in renovascular hypertension. Atrophic kidneys with <20% differential renal function are unlikely contributors to ongoing worsening kidney function but may still contribute to renovascular hypertension.

Rx TREATMENT

ACUTE GENERAL Rx

The treatment of renal artery stenosis must be targeted to the clinical presentation:

- Asymptomatic RAS requires no treatment.
- Patients with chronic hypertension in the setting of incidentally discovered RAS require only antihypertensive medical therapy.
- Patients in whom RVH is suspected should be initially treated with antihypertensive therapy, specifically medications that block the renin-angiotensin-aldosterone system. As discussed later, failure to control blood pressure

on an aggressive regimen represents a reason to consider renal revascularization.
- Patients with ischemic nephropathy should be considered for intervention only if the renal function is rapidly declining or flash pulmonary edema develops in the setting of bilateral renal artery stenosis.

PHARMACOLOGIC THERAPY

- Because of the activation of the renin-angiotensin-aldosterone system in RAS, ACEIs or ARBs are recommended and well tolerated (92%) for the treatment of RVH. Kidney function should be monitored carefully when initiating or titrating these medications, particularly when bilateral RAS (78% tolerability) or unilateral stenosis with solitary kidney is present to avoid precipitating AKI.
- Diuretics should be considered in patients with congestive heart failure or flash pulmonary edema.
- Antiplatelet therapy and statin therapy in patients with atherosclerotic RAS.

NONPHARMACOLOGIC THERAPY

- If either blood pressure cannot be controlled by medications alone, flash pulmonary edema occurs, or there is rapid decline in renal function, referral for renal angiography, angioplasty, and stenting may be indicated.
- Angioplasty without stenting is insufficient for atherosclerotic lesions due to a high failure rate of adequate dilation of the artery or a high rate of restenosis.
- Occasionally a kidney that has lost its function due to RAS may cause refractory hypertension. This situation would be discovered only by renal vein renin sampling in a patient with unilateral renal atrophy. In such cases, nephrectomy of the atrophied kidney may be the best method to control blood pressure.
- Rarely is renal artery bypass required.
- If RAS is suspected as the cause of flash pulmonary edema or rapidly declining kidney function, bilateral disease is likely, and, if confirmed by angiography, both renal arteries should be stented.
- Hypertension is rarely cured with revascularization in patients with atherosclerotic RAS due to high background essential hypertension. The goal of intervention is to gain control of blood pressure and reduce the number of blood pressure medications.
- The ACC/AHA guidelines for clinical indications of renal artery revascularization in the presence of significant stenosis include:
  1. Accelerated, resistant, or malignant hypertension (class IIa)
  2. Hypertension with unilateral small kidney (class IIa)
  3. Hypertension with intolerance to medication (class IIa)
  4. Treatment of cardiac destabilization syndromes such as unexplained heart failure exacerbations or episodes of flash pulmonary edema (class I) and refractory or unstable angina (class IIa)
  5. Progressive chronic kidney disease with bilateral RAS or RAS associated with a solitary functioning kidney (class IIa)
- Many patients who meet these criteria will not demonstrate a beneficial response to renal revascularization. Careful selection of patients for angiography and intervention must be made.
- Multiple randomized controlled trials (e.g., ASTRAL, CORAL, DRASTIC, and STAR) have not shown benefit to percutaneous therapy compared to medical therapy, with end points of blood pressure control, renal function, and cardiovascular events. However, these trials did have several inherent limitations.
  1. DRASTIC trial was a small angioplasty-only trial that demonstrated no difference in blood pressure, but it did show decrease in daily doses of antihypertensive drugs and number of drugs in the intervention group. Crossover was high from the medication arm to the intervention arm.
  2. The ASTRAL trial was a moderate-sized trial of stenting versus medication in RAS that showed no difference in blood pressure control or in the number of antihypertensive medications required to achieve blood pressure control. RAS severity was only moderate in the study population, decreasing the likelihood of finding a positive result.
  3. CORAL is a large, prospective, multicenter trial comparing stenting versus medication in severe RAS (>60% stenosis). This study confirms that with atherosclerotic renal artery stenosis and hypertension, clinical outcomes are not improved by stenting and that renal artery stenting is futile in general. RAS severity was moderate in many patients and may have diluted the beneficial effects of intervention on those with severe RAS.
  4. Follow-up of the CORAL population at 3 yr failed to show any difference in blood pressure control, change in GFR, end-stage renal disease, or death with stenting vs. medical therapy.
- With these limitations in mind, there is no prospective, randomized, controlled trial that has shown a benefit in any subgroup of patients with renal artery stenosis of revascularization over medical management. Therefore it is recommended that the decision to refer a patient for revascularization be made by specialists who are practiced and skilled in handling hypertension and renal artery stenosis.

FIBROMUSCULAR DYSPLASIA

- Medical therapy should include an ACEI or ARB to control blood pressure unless severe bilateral disease is present (rare).
- RVH from fibromuscular dysplasia (FMD) is often cured by renal artery revascularization because many younger patients do not have background essential hypertension.
- In most cases, patients should be referred for renal artery angioplasty regardless of whether blood pressure can be controlled medically.
- Stenting is not appropriate in patients with FMD because angioplasty alone usually yields a durable result. In addition, recurrence of FMD is common, and the presence of stents may hinder additional interventions.
- Renal artery bypass may be necessary in patients whose FMD recurs multiple times or in whom angioplasty failed to yield an improvement in blood pressure.

DISPOSITION & REFERRAL

- Patients with uncontrolled hypertension on multiple agents should be referred for management by a hypertension specialist.
- Percutaneous intervention for atherosclerotic RAS must be reserved for selected patients until further data are available.

PEARLS & CONSIDERATIONS

- Renal artery stenosis is most commonly an incidental finding and clinically silent.
- Renal artery stenosis may present as hypertension, renal dysfunction, or both, or flash pulmonary edema.
- Stenting is inappropriate for most patients with RAS. Consideration should be made only in high-risk patients and after consultation with a specialist in the field.
- The modality for the type of imaging should depend on the expertise of the institution.

BASIC INFORMATION

DEFINITION

Renal cell carcinoma (RCC) is a primary carcinoma originating in the renal parenchyma from the malignant transformation of proximal renal tubular epithelial cells. The majority of renal cell cancers are of clear cell type; papillary tumors comprise 15%, and chromophobe cancers comprise 10%.

SYNONYMS

Hypernephroma
RCC
Renal cell adenocarcinoma

ICD-10CM CODES

C64.9	Malignant neoplasm of kidney, except renal pelvis
C64.1	Malignant neoplasm of right kidney, except renal pelvis
C64.2	Malignant neoplasm of left kidney, except renal pelvis
C64.9	Malignant neoplasm of unspecified kidney, except renal pelvis
C65.9	Malignant neoplasm of renal pelvis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: In 2019, there were an estimated 73,820 new cases and 14,770 deaths in the U.S. Two percent of cases of renal cancer are associated with inherited syndromes.
PREDOMINANT SEX: Male:female ratio is approximately 2:1.
PREDOMINANT AGE: Peak incidence is at age 50 to 70 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients are often asymptomatic until they have advanced disease. Paraneoplastic syndromes such as hypercalcemia, erythrocytosis, anemia, and hepatic dysfunction may occur with renal cell carcinoma. The classic triad of flank pain, hematuria, and a palpable abdominal mass currently represents an unusual presentation. Current presenting findings in RCC include:

Hematuria	50-60%
Elevated erythrocyte sedimentation rate	50%-60%
Abdominal mass	25%-45%
Anemia	20%-40%
Flank pain	35%-40%
Hypertension	20%-40%
Weight loss	30%-35%
Fever	5%-15%
Hepatic dysfunction	10%-15%
Classic triad (hematuria, abdominal mass, flank pain)	5%-10%
Hypercalcemia	3%-6%
Erythrocytosis	3%-4%
Varicocele	2%-3%

ETIOLOGY

Hereditary forms:
- Familial renal carcinoma
- Renal carcinoma associated with Von Hippel-Lindau disease
- Hereditary papillary renal cell carcinoma

Risk factors:
- Cigarette smoking
- Obesity
- Phenacetin-containing analgesics
- Asbestos, lead, Thorotrast, and chromium exposure
- Gasoline and other petroleum products
- Role of the *VHL* gene on chromosome 3

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Transitional cell carcinomas of the renal pelvis (8% of all renal cancers)
- Wilms tumor
- Other primary renal carcinomas and sarcomas
- Renal cysts
- Retroperitoneal tumors

WORKUP

LABORATORY TESTS:
- Urinalysis: Hematuria
- Complete blood count: Anemia or erythrocytosis
- Chemistry panel: Renal failure and electrolyte issues, including hypercalcemia
- Liver function tests: Hepatic dysfunction with elevated alkaline phosphatase, prolonged prothrombin time, and hypoalbuminemia

IMAGING STUDIES

Nearly 50% of renal cancers are now detected because a renal mass is incidentally detected on radiographic evaluation.
- Renal ultrasound
- Abdominal CT scan with contrast (Figs. E1 and 2); CT-guided biopsy is generally not necessary for diagnosis of solid masses >4 cm (high likelihood of cancer)
- MRI
- Renal arteriogram
- Intravenous pyelography

STAGING

See Table 1.

COMMON SITES OF METASTASES

Lung	50%-60%
Bone	30%-40%
Regional nodes	15%-30%
Main renal vein	15%-20%
Perirenal fat	10%-20%
Adrenal (ipsilateral)	10%-15%
Vena cava	10%-15%
Brain	10%-15%
Adjacent organs (colon, pancreas)	10%
Kidney (contralateral)	2%

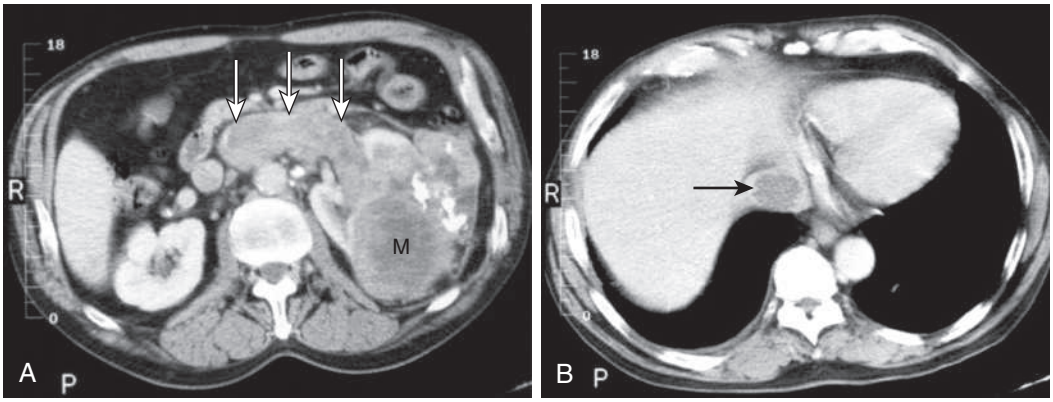

FIG. 2 Renal cell carcinoma. In this patient, the computed tomography scan at the midportion of the kidneys **(A)** demonstrates a large left renal mass *(M)* that extends into the renal vein and into the inferior vena cava *(arrows)*. **B,** An image at the level of the base of the heart shows that the tumor thrombus *(arrow)* extends into the right atrium. (From Mettler FA Jr: *Essentials of radiology,* ed 3, Philadelphia, 2014, Saunders.)

TABLE 1 TNM Staging of Renal Cell Carcinomas as per the AJCC Eighth Edition

T Stage	Description
T_x	Tumor cannot be assessed
T_1: Tumor ≤7 cm, limited to kidney	T_{1a}: Tumor <4 cm T_{1b}: Tumor ≥4 cm to ≤7 cm
T_2: Tumor >7 cm, limited to kidney	T_{2a}: Tumor >7 cm but ≤10 cm T_{2b}: Tumor >10 cm
T_3: Tumor extending into major veins or perinephric tissue but not into ipsilateral adrenal gland or beyond Gerota fascia	T_{3a}: Tumor extends to renal vein/branches or invades perirenal and/or renal sinus fat T_{3b}: Tumor extends into IVC below diaphragm T_{3c}: Tumor extends into IVC above diaphragm or wall of IVC
T_4	Tumor invades beyond Gerota fascia (including contiguous extension into ipsilateral adrenal gland)
N stage	**Description**
N_x	Regional nodes cannot be assessed
N_1	No regional nodes involved
N_2	Metastasis in regional node(s)
M stage	**Description**
M_0	No distant metastases
M_1	Distant metastasis present
Stage	**TNM grouping**
I	$T_1N_0M_0$
II	$T_2N_0M_0$
III	$T_3N_0M_0$ or $T_{1-3}N_1M_0$
IV	$T_4N_{any}M_{any}$ or $T_{any}N_{any}M_1$

AJCC, American Joint Committee on Cancer; *IVC,* intravenous cholangiography; *TNM,* tumor, node, metastases.

Rx TREATMENT

- Surgery:
  1. Surgical nephrectomy (open procedure or laparoscopic approach) is the only effective management for stages I, II, and some stage III tumors. Although radical nephrectomy had long been the standard treatment, retrospective studies have shown that partial rather than radical nephrectomy is associated with improved survival and is appropriate for patients with renal cell neoplasms <4 cm that are not adjacent to the renal pelvis or invading the vena cava.
  2. Laparoscopic robotic-assisted nephrectomy has been adopted in multiple centers, primarily for nephron-sparing surgery in the case of tumors <4 cm. Advantages include less blood loss, minimal effects on renal function, and similar oncologic outcomes. Disadvantages include increased costs and limitations in tumor size and locations eligible for robotic surgery.
  3. Various forms of partial nephrectomy may be available for patients with bilateral cancers or with a solitary kidney.
  4. Cytoreductive nephrectomy in patients with metastatic RCC before immunotherapy improved survival in patients compared with immunotherapy alone on the basis of randomized trials data. However, recent results from the randomized Clinical Trial to Assess the Importance of Nephrectomy (CARMENA) demonstrated no benefit for intermediate- and poor-risk patients in the setting of modern tyrosine kinase inhibitor (sunitinib) therapy. Additional trials data are awaited to assess the role of nephrectomy in favorable risk patients and with the use of neoadjuvant tyrosine kinase inhibitor therapy.
- Angioinfarction, cryoablation, or radiotherapy (for palliation).
- Systemic therapy:
  1. In patients with unresectable disease, therapy with the multi-targeted tyrosine kinase inhibitors axitinib, sunitinib, pazopanib, cabozantinib, lenvatinib, and sorafenib and also mTOR kinase inhibitors such as everolimus and temsirolimus can be used as therapy. Typically, patients are offered sequential therapy with either of these agents until maximum response duration or onset of major toxicity from each agent. The majority of responses with these agents are typically either partial or stable disease, and relapse is the norm.
  2. Checkpoint inhibitors: The checkpoint inhibitors have demonstrated efficacy in both treatment-naïve and previously treated patients. Combination checkpoint inhibition with ipilimumab combined with nivolumab has demonstrated superior efficacy for patients with IMDC intermediate and poor risk treatment-naïve patients. Furthermore, therapeutic regimens combining tyrosine kinase inhibition plus immune checkpoint inhibition also have demonstrated superiority in all risk groups for axitinib plus pembrolizumab and also axitinib plus avelumab compared to sunitinib monotherapy.
  3. Immunotherapy: High-dose interleukin-2 therapy may achieve a 15% response rate, which is often durable and associated with long-term survival in highly selected patients with excellent performance status. Severe toxicities associated with this therapy have limited the use of this approach.

PROGNOSIS

The 5-yr survival rate among patients with kidney cancer has increased from 57% in 1987-1989 to 74% in 2006-2012. The prognosis of surgically treated patients is shown in the following:

TNM Stage	5-yr Survival (%)
I	95
II	88
III (renal vein or vena cava)	50-60
III (nodal involvement)	15-25
IV	5-20

REFERRAL

- To urologist for staging and surgery
- To medical oncologist if metastatic disease is present

PEARLS & CONSIDERATIONS

- Patients should be considered for nephron-sparing surgery in case of smaller tumors (<4 cm).
- Laparoscopic robotic-assisted surgery is utilized for standard nephron-sparing surgery routinely; it is utilized for central tumors and tumors >4 cm in some experienced centers.
- Adjuvant therapy utilizing tyrosine kinase inhibitors has showed mixed results when used in the postresection setting and is not approved for use in this setting. An intergroup study showed no survival benefit, whereas a smaller study limited to high-risk patients showed a progression-free survival benefit.
- High-dose interleukin-2 can lead to long-term remissions in 10% to 15% of carefully selected patients.

Renal Tubular Acidosis

BASIC INFORMATION

DEFINITION

Renal tubular acidosis (RTA) is a group of chronic diseases characterized by hyperchloremic metabolic acidosis (HCMA) produced by inability of the renal tubules to either excrete hydrogen ion (H^{+}) or retain bicarbonate ion (HCO_3^-). Factors differentiating types of RTA are described in Table 1. Four main types of RTA are described:

- Type 1 (classic, distal RTA): Abnormality in distal tubule hydrogen secretion, resulting in hypokalemic HCMA
- Type 2 (proximal RTA): Decreased proximal tubule bicarbonate reabsorption, resulting in hypokalemic HCMA
- Type 3 (mixed RTA): Rare autosomal recessive disorder with features of distal and proximal RTA
- Type 4 (hyporeninemic, hypoaldosteronism RTA): Aldosterone deficiency or a disease of the cortical collecting duct characterized by decreased distal sodium reabsorption and decreased distal tubule acidification hyperkalemic HCMA

SYNONYM

RTA

ICD-10CM CODE

N25.89 Other disorders resulting from impaired renal tubular function

EPIDEMIOLOGY & DEMOGRAPHICS

RTA type 4 affects primarily adults, whereas RTA types 1 and 2 are more frequent in children.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Examination may be normal.
- Reduced skin turgor may be present from polyuria and dehydration.
- Muscle weakness and aches, paralysis, and cardiac arrhythmias from hypokalemia may occur.
- Low back pain and bone pain may be present in patients with abnormalities of calcium and phosphorus metabolism (RTA type 2).
- Failure to thrive or delayed growth in children.
- Some patients may present with sensorineural deafness in RTA type 1 (H^+–ATPase mutations).

ETIOLOGY

- Type 1 RTA inherited as a primary disorder with mutation of the basolateral chloride–bicarbonate exchanger (*SLC4A1* gene) or apical proton–ATPase (H^+–ATPase). Acquired causes: Autoimmune disorders (SLE, Sjögren syndrome); primary biliary cirrhosis and other liver diseases; medications (amphotericin, NSAIDs, lithium carbonate, ifosfamide); genetic disorders (Ehlers–Danlos syndrome, Marfan syndrome, hereditary elliptocytosis); toxins (toluene); disorders with nephrocalcinosis (primary hyperparathyroidism, vitamin D intoxication, idiopathic hypercalciuria); and tubulointerstitial disease (renal transplantation, renal medullary cystic disease, obstructive uropathy, chronic urinary tract infections, and analgesic nephropathy)
- Type 2 RTA includes inherited disorders such as proximal tubule cell sodium bicarbonate co-transporter (NBCe1) defect, carbonic anhydrase type 2 deficiency, and Fanconi syndrome (caused by cystinosis, Wilson disease, hereditary fructose intolerance, Lowe syndrome, Fanconi-Bickel syndrome, Dent disease, tyrosinemia, galactosemia). Acquired causes include primary hyperparathyroidism, multiple myeloma, amyloidosis, light chain deposit diseases, heavy metals (copper, lead, mercury, and cadmium), chronic rejection of a transplanted kidney, and medications (acetazolamide, topiramate, outdated tetracycline, ifosfamide, zidovudine, didanosine, aminoglycosides)
- Type 3 RTA: Rare inherited recessive disorder with carbonic anhydrase (CA) 2 deficiency, drugs (topiramate)
- Type 4 RTA includes inherited disorders such as pseudohypoaldosteronism type 1 or type 2 (Gordon syndrome). Acquired causes include diabetes mellitus, HIV/AIDS, sickle cell disease, obstructive uropathy, lupus, amyloidosis, adrenal insufficiency, kidney transplant rejection, drugs (spironolactone, eplerenone, amiloride, angiotensin-converting enzyme [ACE] inhibitors, angiotensin-receptor blockers [ARBs], trimethoprim, pentamidine, heparin, NSAIDs, and calcineurin inhibitors [cyclosporine, tacrolimus])

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS: EXTRARENAL ORIGIN

- Diarrhea with significant bicarbonate loss
- External loss of biliary and pancreatic secretions
- Gastrointestinal-urinary diversion procedures (e.g., ureterosigmoidostomy, ileal conduit)
- Respiratory acidosis
- Drugs: Calcium chloride, magnesium sulfate, cholestyramine

WORKUP

Detection of HCMA by serum electrolyte and arterial blood gas (ABG) analysis followed by evaluation of potential causes (see "Etiology"). Fig 1 describes an approach to the patient with RTA.

LABORATORY TESTS

- ABG reveals metabolic acidosis.
- Anion gap is normal.
- Serum potassium is low in RTA types 1 and 2, normal in type 3, and high in type 4.
- First-morning urine pH is >5.5 in RTA type I, <5.5 in types 2 and 3, and <5.5 (low mineralocorticoid secretion) or >5.5 (collecting duct abnormality) in RTA type 4.
- Urinary anion gap (UAG) is an indirect evaluation of urinary ammonium excretion, which differentiates renal from extrarenal causes of normal anion gap metabolic acidosis (e.g., diarrhea). UAG is 0 or positive in all types of RTA.
- $UAG = U_{(Na + K)} - U_{Cl}$.
- UAG is valid only if U_{Na} >20 mEq/L and urine pH <6.5.
- Urine osmolar gap (UOG) is an independent surrogate of urinary ammonium concentration and is not affected by the presence of other non-reabsorbable anions (e.g., keto acids, 5-oxoproline/pyroglutamic acid, bicarbonate, or hippurate).
- Calculated $U_{NH4}^+ = 0.5$ (measured Uosm – calculated Uosm [2 (Na + K) + Urine Urea (mg/dl/2.8) + glucose (mg/dl/18]).
- Calculated urine ammonium ≥75 mEq/L denotes intact renal tubular function and supports an extrarenal origin of HCMA.

TABLE 1 Contrasting Features and Diagnostic Studies in Renal Tubular Acidosis

Finding	Types of Renal Tubular Acidosis		
	Proximal (Type 2)	Classical Distal (Type 1)	Generalized Distal Dysfunction (Type 4)
Plasma potassium	Low	Low	High
Urine pH during metabolic acidosis (ABG pH <7.3)	<5.5	>5.5	<5.5 or >5.5
Urine net charge	Positive	Positive	Positive
Fanconi lesion	Present	Absent	Absent
Fractional bicarbonate excretion	10%-15%	2%-5%	5%-10%
Urine–Blood PCO_2	Normal	Low	Low
H^+–ATPase defect		Low	
HCO_3^-/Cl^- transporter defect		High	
Amphotericin B		Normal	
Response to therapy	Least responsive	Responsive	Less responsive
Associated features	Fanconi syndrome	Nephrocalcinosis/ hypergammaglobulinemia	Chronic kidney disease

ATPase, Adenosine triphosphatase; (U – B) *PCO_2,* urine–blood CO_2 tension difference, <30 is low.
Modified from DuBose TD: Disorders of acid–base balance. In *Brenner and Rector's the kidney,* ed 9, Philadelphia, 2011, WB Saunders.

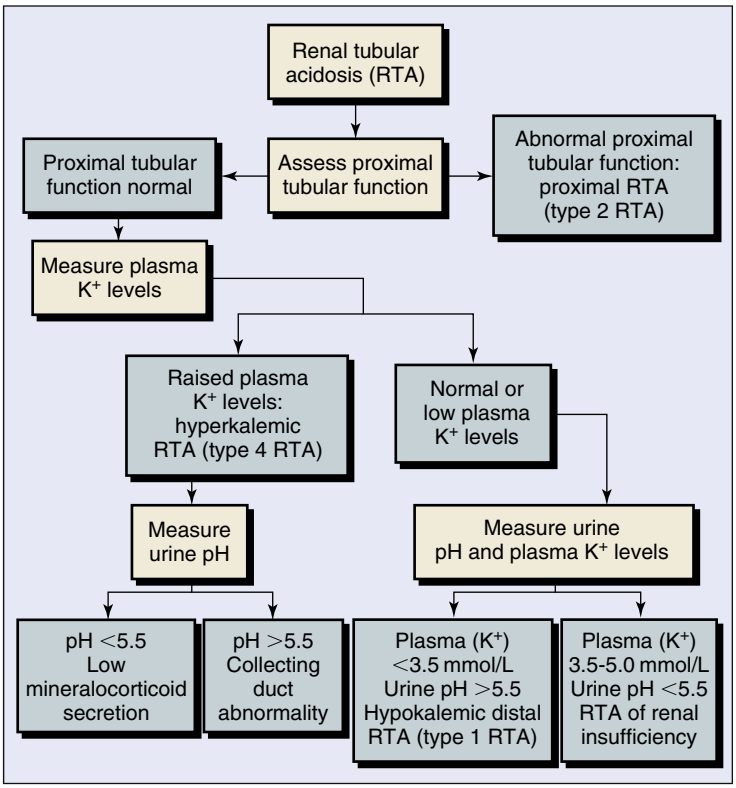

FIG. 1 Approach to the patient with renal tubular acidosis. (From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, WB Saunders.)

- Calculated urine ammonium ≤25 mEq/L denotes inappropriately low concentration.
- UOG cannot be used if there are other neutral substances in the urine (e.g., mannitol, alcohols) or during a urinary tract infection urease-producing bacteria.
- Additional studies include urine and serum calcium concentrations.
- Parathyroid hormone measurement when primary hyperparathyroidism is suspected (type 2 RTA).

IMAGING STUDIES

- Plain abdominal radiographs for evaluation of nephrocalcinosis
- Kidney ultrasound to determine kidney sizes or presence of stones
- Non–contrast-enhanced CT scan in patients with nephrocalcinosis or nephrolithiasis

Rx TREATMENT

ACUTE GENERAL Rx

- Types 1 and 2 are treated with oral sodium bicarbonate (1 to 2 mEq/kg/day in RTA type I, 2 to 4 mEq/kg/day in RTA type 2) titrated to correct metabolic acidosis (serum bicarbonate >22 mEq/L).
- Potassium supplementation is required for hypokalemic patients.
- Type 4 RTA can be treated with diuretics to lower elevated potassium levels and with sodium bicarbonate to correct significant acidosis. Fludrocortisone 0.1 to 0.3 mg/day can be used to correct mineralocorticoid deficiency.

CHRONIC Rx

- Monitor potassium levels in RTA type 4.
- Monitor for bone disease (osteomalacia) in RTA type 2.
- Monitor for nephrolithiasis and nephrocalcinosis in RTA type I.

DISPOSITION

- Prognosis varies with the associated conditions (see "Etiology").
- Untreated distal RTA may result in hypocalcemia, hypophosphatemia, nephrolithiasis, and nephrocalcinosis.

PEARLS & CONSIDERATIONS

- Non-anion gap metabolic acidosis: Check for urine ammonium (urine anion and osmolar gaps) to differentiate nonrenal vs. renal causes of HCMA.
- Examine serum potassium to differentiate between RTA types 1 or 2 vs. type 4.
- In type 4 hyperkalemic RTA, carefully review medication list and rule out urinary obstruction, especially in elderly males.

COMMENTS

Patient education material can be obtained from the National Kidney and Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893.

SUGGESTED READINGS

Available at ExpertConsult.com

AUTHOR: **Jian Li, MD, PhD**

Renal Vein Thrombosis

BASIC INFORMATION

DEFINITION

Renal vein thrombosis (RVT) is the thrombotic occlusion of one or both renal veins.

ICD-10CM CODE

I82.3 Embolism and thrombosis of renal vein

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence unknown; probably an underdiagnosed condition
- May occur at any age with no gender preference
- Epidemiology tied to the underlying cause

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Acute bilateral renal vein thrombosis:
- Back and bilateral flank pain
- Acute renal failure

Acute unilateral renal vein thrombosis:
- Flank pain
- Decline in renal function
- Hematuria
- Increase in the amount of proteinuria if associated with nephrotic syndrome

Chronic unilateral renal vein thrombosis:
- May be silent
- Pulmonary emboli and hemolysis
- Back pain
- Deep vein thrombosis in lower extremities
- Edema
- Glycosuria
- Hyperchloremic acidosis
- Left varicocele (if the left renal vein is thrombosed)
- Dilated abdominal veins

ETIOLOGY & PATHOGENESIS

- Nephrotic syndrome, especially when the serum albumin is <2 g/dl
- Extrinsic compression by a tumor or retroperitoneal mass
- Invasion of the renal vein or inferior vena cava by tumor (almost always renal cell cancer)
- Trauma
- Other hypercoagulable states
- Severe dehydration

NOTE: For unknown reasons, diabetic nephropathy is not commonly associated with renal vein thrombosis, even if the nephrotic syndrome is present.

Controversy has existed regarding whether the renal vein thrombosis association with nephrotic syndrome is a complication of nephrotic syndrome or whether renal vein thrombosis occurring in the setting of increased renal vein pressure (e.g., with congestive heart failure, constrictive pericarditis, or extrinsic compression) can independently cause proteinuria. Current evidence is that renal vein thrombosis does not cause nephrotic syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The diagnosis of renal vein thrombosis does not include any differential consideration. The differential diagnosis is that of proteinuria. Renal vein thrombosis should be considered if proteinuria worsens or if renal function worsens in a patient with glomerulonephritis. Renal vein thrombosis should also be considered in patients with pulmonary emboli and no lower-extremity deep vein thrombosis.

WORKUP

Clinical suspicion (see "Differential Diagnosis") and imaging studies

IMAGING STUDIES

- Abdominal ultrasound with Doppler (Fig. E1)
- Abdominal MRI or CT with contrast (Fig. 2) in the absence of significant renal failure
- Renal arteriography (delayed films during venous phase)
- Selective renal vein venography
- Renal biopsy may be indicated if evidence of nephritis is present (e.g., active urinary sediment)

TREATMENT

- Anticoagulation with heparin or low-molecular-weight heparin as a bridge to coumadin in acute renal vein thrombosis to prevent pulmonary emboli and in attempt to improve renal function and decrease proteinuria.
- Note that patients with nephrotic syndrome can be resistant to heparin because of antithrombin III deficiency.
- Direct thrombin and factor Xa inhibitors have not been studied in patients with nephrotic syndrome. However, there are case reports of their effectiveness in patients who have contraindications or refuse warfarin or low-molecular-weight heparin.
- Local thrombolytic therapy with or without endovascular thrombectomy has also been reported to be effective, particularly for patients with acute renal vein thrombosis with evidence of acute renal failure.
- The value of anticoagulation in chronic renal vein thrombosis is dubious. The exception is in nephrotic patients with membranous glomerulonephritis with profound hypoalbuminemia, where prolonged prophylactic anticoagulation may be of benefit even if renal vein thrombosis has not been documented.

PROGNOSIS

Probable worsening of the underlying nephropathy by acute renal vein thrombosis; the effect of chronic renal vein thrombosis is unclear.

AUTHOR: **David J. Lucier, Jr., MD, MBA, MPH**

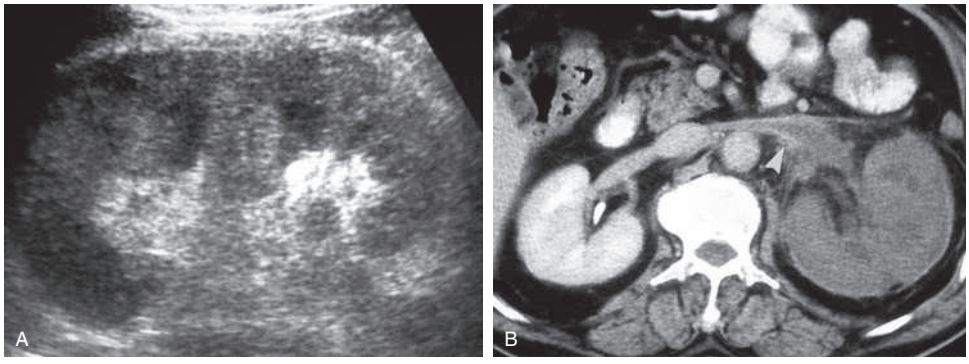

FIG. 2 Renal vein thrombosis. A, Sagittal sonogram demonstrates a diffusely enlarged, edematous left kidney with loss of corticomedullary differentiation. **B,** Confirmatory contrast-enhanced computed tomography shows a large, poorly perfused left kidney and thrombus in the left renal vein *(arrowhead).* (From Rumack CM et al: *Diagnostic ultrasound,* ed 4, Philadelphia, 2011, Elsevier.)

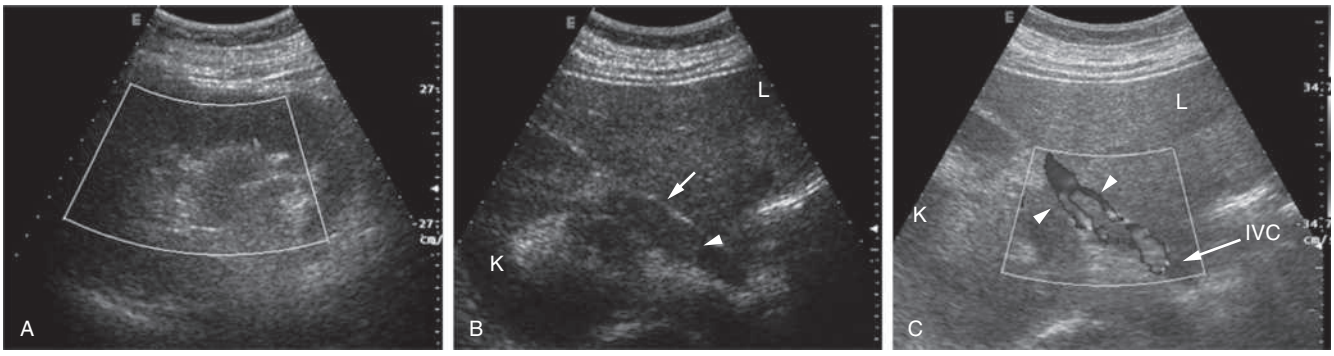

FIG. E1 Bilateral renal vein thrombosis in a patient with nephritic syndrome secondary to focal glomerulosclerosis. Male, age 23, with normal glomerular filtration rate (GFR) and proteinuria 12 to 17 g/day. Ultrasonographic evaluation was required after acute worsening of GFR and low back pain (serum creatinine was 3.7 mg/dl). Right kidney longitudinal diameter was 14 cm and it appeared hypoechoic, globose-shaped and hypoperfused **(A).** Resistive indexes were 0.68. Right renal vein showed a hypoechoic material *(white arrow)* filling most part of the lumen *(arrowhead)* **(B).** After systemic anticoagulant therapy **(C),** the vein showed a partial recanalization with thin flow signals *(arrowheads)* around the thrombus. The progressive improvement in vessel perfusion occurred together with functional recovery. *IVC,* Inferior vena cava; *K,* kidney; *L,* liver. Respiratory Syncytial Virus

BASIC INFORMATION

DEFINITION

Respiratory syncytial virus (RSV) is an RNA virus that tends to form syncytia in tissue culture. RSV causes repeated acute respiratory tract infections in people of all ages. It is highly contagious and is the leading cause of severe lower respiratory tract infections in infants and young children, while it usually manifests as upper respiratory infections, bronchiolitis, or tracheobronchitis in older children and adults.

SYNONYMS

Bronchiolitis
RSV

ICD-10CM CODES

B97.4	Respiratory syncytial virus as the cause of diseases classified elsewhere
J12.1	Respiratory syncytial virus pneumonia
J20.5	Acute bronchitis due to respiratory syncytial virus
J21.0	Acute bronchiolitis due to respiratory syncytial virus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Humans are the only source of infection. There are 64 million infections worldwide annually, resulting in 160,000 deaths; it is associated with >57,000 U.S. pediatric hospitalizations annually and 2 million outpatient visits each yr among children <5 yr. It is the leading cause of lower respiratory tract infection in young children worldwide.

PREVALENCE: Nearly everyone is infected by age 2, with reinfections occurring at all ages.

PREDOMINANT SEX AND AGE: Male sex may predispose to more severe respiratory disease in RSV infection. Age predominance in infancy and the elderly.

PEAK INCIDENCE: In nontropical areas of the Northern Hemisphere, seasonal outbreaks usually occur November to April, with a peak in January or February; in nontropical areas of the Southern Hemisphere, May to September, with a peak in May, June, or July. In the tropics, seasonal outbreaks usually occur during the rainy season. Incubation ranges from 2 to 8 days; although 4 to 6 days is most common.

RISK FACTORS: For children, risk factors include attending daycare or school and inpatient hospitalization. Severe disease is seen primarily in infants and young children (especially those born before 35 wk of gestation); the elderly; and in patients with cardiac, pulmonary, or immune system dysfunction.

GENETICS: Severe disease is associated with polymorphisms in various interleukins and CCR5.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical findings include fever, tachypnea, prolonged expiration, wheezes and rales, cough, rhinorrhea, coryza, conjunctivitis, and otitis media. Clinical presentation can include pneumonia and bronchiolitis.

ETIOLOGY

Humans are the only known reservoir. Transmission is by large respiratory droplets via close contact or contaminated surfaces, where it can survive for several hours. The CDC recommends hand washing, gowns, and gloves to prevent nosocomial infection, which is especially common on pediatric wards. However, the CDC does not recommend excluding children with respiratory illnesses who are well enough to attend school or daycare, as RSV is often spread during early stages of illness.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Influenza, parainfluenza, and adenovirus

WORKUP

- History with a focus on upper and lower respiratory symptoms, fever, and (in infants) apnea
- Focused physical exam including temperature and pulse oximetry, as well as lung and head, eyes, ears, nose, and throat (HEENT) exam

LABORATORY TESTS

Nasopharyngeal specimens can be analyzed using rapid diagnostic assays, such as immunofluorescent and enzyme immunoassay techniques for detection of viral antigen and are generally reliable in infants and young children. Virus isolation is also possible, but requires 1 to 5 days and accuracy may vary. Serologic testing (serum antibodies) is less useful because it is unreliable in infants and is confounded in other patients due to repeated infections.

IMAGING STUDIES

Chest x-ray for suspected pneumonia, but not routinely in suspected bronchiolitis

TREATMENT

NONPHARMACOLOGIC THERAPY

Early diagnosis and isolation techniques are important in limiting spread of RSV infections.

ACUTE GENERAL Rx

Primary treatment is predominantly supportive in nature. May include hydration, clinical assessment of respiratory status, measurement of oxygen saturation, supplemental oxygen, bronchodilators, suction of the upper airway, nebulized hypertonic saline, and, if required, intubation and mechanical ventilation.

- Mild disease: Symptomatic treatment and supportive therapy.
- Severe disease may require oxygen therapy, bronchodilators, hospitalization, intubation, and mechanical ventilation. The use of corticosteroids remains controversial, especially in infants, and is not recommended by the American Academy of Pediatrics.
- Avoid sports drinks, soft drinks, undiluted fruit juice, or water. These beverages may contain too much sugar, contain too few calories, or lack the proper balance of essential minerals.
- Reduce fever with acetaminophen or ibuprofen.
- Antibiotics may be used to treat a bacterial infection (such as pneumonia) that develops as a complication.
- Ribavirin is not recommended for routine use but may be indicated in specific situations, such as for treatment of severe lower respiratory tract RSV infections in pediatric and adult patient populations with additional underlying compromising conditions such as chronic lung conditions, prematurity, borderline personality disorder (BPD), congenital heart disease, immunodeficiency, immunosuppression, or organ transplantation. It may also be used in selected patients with documented, potentially life-threatening RSV. Updated eligibility criteria for treatment may change, and updates should be sought from the American Academy of Pediatrics Red Book in its print or online version. Further studies are needed. New research in the field of RNA interference-based agents has shown promising results for the treatment of acute RSV infection but is still in phase II trials. Ribavirin is a Federal Drug Administration Pregnancy Category X product, indicating that its use is contraindicated in women who are pregnant. It also should not be taken by women who are breastfeeding.

REFERRAL

To pulmonology and infectious disease specialists for severe disease or when use of ribavirin is considered; hospitalization for those with respiratory compromise

PEARLS & CONSIDERATIONS

PREVENTION

Primary prevention is through avoidance of transmission through hand washing, proper procedures to avoid spread in health care facilities, and diagnosis of suspected cases.

No benefit has been found from the use of RSV prophylaxis intravenous immunoglobulin (IVIG) or RSV immune globulin (IG) monoclonal antibody, and RSV-IVIG is no longer available. Palivizumab, a humanized mouse monoclonal antibody, may be used in certain infants and children to reduce the risk of lower tract disease, in those with chronic lung disease of prematurity, history of preterm birth, or with congenital heart disease. Updated eligibility criteria for prophylaxis may change, and consultation with pulmonary or infectious disease specialists is recommended.

PATIENT & FAMILY EDUCATION

Hand washing with soap and water for 15 to 20 seconds, covering mouth and nose when coughing or sneezing, avoiding sharing cups and eating utensils with those who may be infected, and refraining from kissing loved ones possibly infected may all aid in preventing future infection. Avoid visiting infected child in the hospital. Avoid secondhand smoke, which irritates the mucous membranes of the nose, sinuses, and lungs of the affected patients and makes them more susceptible to infections.

BASIC INFORMATION

DEFINITION

Restless legs syndrome (RLS) is an awake phenomenon consisting of an urge to move legs, usually associated with feeling of discomfort in legs. Symptoms typically are present only at rest and at least partially improve with movement. Additionally, symptoms are usually worse at night. RLS can result in sleep disturbance with associated executive dysfunction and depression.

SYNONYMS

RLS
Wittmaack-Ekbom syndrome

ICD-10CM CODE
G25.81 Restless legs syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Average prevalence rate is 1% to 29%. Prevalence estimates in Europe are around 10%, and 0.1% to 12% in East Asian population.
PEAK PREVALENCE: 10% in persons aged 30 to 79 and 19% in persons aged 80 or above
PREDOMINANT SEX: Early-onset RLS is more common in females, with 2:1 female/male ratio.
PREDOMINANT AGE: Prevalence of RLS increases with age, and it is more commonly seen in the elderly population.
GENETICS: Genetic basis of RLS has been reported, particularly in early-onset RLS.

- Autosomal dominant disorder
- Common among first-degree relatives
- RLS associated with certain sequences in chromosomes 6p, 12q, 14q, 9p, 20p, 2p, 16p
- These include polymorphisms in the genes *BTBD9, MEIS1, PTPRD, MAP2K5, SKOR1,* and *TOX3*

RISK FACTORS:

- Iron deficiency anemia (IDA)—25% to 35%.
- Pregnancy: Increases in severity and prevalence with each passing trimester.
- End-stage renal disease (ESRD) requiring hemodialysis: Improves with transplant but not dialysis.
- Many neurologic diseases such as Parkinson disease, multiple sclerosis, neuropathy, and myelopathy increase risk as do mood disorders, other inflammatory disease, and cardiovascular disease.

CLASSIFICATION

- Primary RLS is without any obvious cause, with no associated disorder.
- Secondary RLS results from other medical conditions.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Wide spectrum of severity of clinical manifestations has been reported in RLS.
- Most common symptom is unpleasant sensations in legs ("dysesthesias"), reported as discomfort or "creepy-crawling" sensations, mostly bilateral. Arms are occasionally involved.
- There is an extreme urge to move legs, and relief is sustained as long as the movement continues.
- Symptoms are worse at night or evening. Best sleep is usually early in the morning.

ETIOLOGY

The exact etiology remains unknown. Pharmacologic, pathologic, physiologic, and imaging studies have implicated dopaminergic pathways, brain iron metabolism, and endogenous opioid pathways.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Periodic limb movement disorder (PLMD)
- Nocturnal leg cramps
- Painful peripheral neuropathy
- Akathisia
- Positional discomfort
- Volitional movements, foot tapping, leg rocking

WORKUP

- Diagnosis of RLS is based on established clinical criteria (Table 1) and normal neurologic examination.
- Testing is done to determine possible cause of secondary RLS. All patients with RLS should be screened for iron deficiency because iron supplementation in patients with iron deficiency may resolve the symptoms.
- Polysomnography with leg activity monitors to determine limb movements during sleep, but they are unable to distinguish periodic limb movements from periodic movements associated with sleep apnea.
- Nerve conduction studies and electromyography for associated peripheral neuropathy.

LABORATORY TESTS

- Iron status: Serum ferritin, total iron binding capacity, percent saturation
- CBC for anemia in case of iron deficiency
- Metabolic panel: Blood urea nitrogen and serum creatinine for renal insufficiency

IMAGING STUDIES

No imaging studies are required for diagnosis of RLS.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of caffeine, alcohol, and nicotine, which can exacerbate RLS.
- Review and adjustment of medications that may exacerbate or cause RLS (selective serotonin reuptake inhibitors, dopamine blocking agents, stimulants).
- Physical and mental activity.
- Good sleep hygiene.
- Monitoring for depression as RLS has an elevated suicide risk. Bupropion may be the best agent for depression in RLS due to lack of dopamine effects.

CHRONIC Rx

Once the diagnosis of RLS is considered based on clinical criteria as mentioned in Table 1 and causes impairment of quality of life, an anticonvulsant (gabapentin enacarbil or pregabalin) or dopamine agonist (bromocriptine, pramipexole, or ropinirole) should be started at low dose and then gradually tapered depending on tolerance.

Treatment options (Table 2) for RLS include:

- Anticonvulsants, such as gabapentin, have been shown to be effective in multiple studies. Gabapentin enacarbil and pregabalin would now be considered first-line agents in the treatment of RLS. These agents do not cause iatrogenic worsening (augmentation) of RLS with long-term treatment. Limited case reports support use of lamotrigine and topiramate in patients who are intolerant of other agents.
- Dopaminergic agents such as levodopa and dopamine agonists help to ameliorate RLS symptoms, decrease periodic limb movements, and improve sleep. Dopamine agonists, pramipexole and ropinirole, can be first-line agents in the treatment of RLS but often cause augmentation of RLS with long-term treatment.

TABLE 1 Diagnostic Criteria for Restless Legs Syndrome

Minimal Criteria

- Desire to move the legs usually associated with paresthesias
- Motor restlessness, as characterized by floor pacing, leg rubbing, stretching, and flexing
- Worse at rest, with relief by activity
- Worse at night

Additional Criteria

- Sleep disturbances, as difficulty in sleep onset and maintaining sleep, daytime fatigue, or somnolence
- Involuntary movements, as periodic limb or leg movements in sleep and periodic or aperiodic limb movements while awake
- Neurologic examination is normal in idiopathic restless legs syndrome
- Clinical course may begin at any age but most severe in middle and older age
- Family history suggests autosomal dominant mode of inheritance in one third of the cases

From Stiansy K et al: Clinical symptomatology and treatment of restless leg syndrome and periodic limb movement disorder, *Sleep Med Rev* 6(4):253-265, 2002.

TABLE 2 Management of Restless Legs Syndrome LS/WED

Agent and Daily Dosage	Side Effects	Countermeasures
Step 1: α2δ Agents		
First-line treatment, particularly if sleep disturbance, pain, or anxiety is present		
Gabapentin enacarbil, 300-600 mg Pregabalin, 50-450 mg* Gabapentin, 100-1800 mg*	Dizziness	Reduce dose and add alternate medication class as needed. If fall risk, then discontinue and change to alternate medication class.
	Somnolence, daytime fatigue	Reduce dose and add alternate medication class as needed. If significant, discontinue and change to alternate medication class.
	Tolerance	Discontinue, take drug holiday with return to medication. Switch to alternate medication class.
	Weight gain	Reduce dose and add alternate medication class as needed. If significant, discontinue and change to alternate medication class.
Step 2: Dopamine Agonists		
Alternative first-line treatment if depression is present and dose kept low.		
Pramipexole, 0.125-0.5 mg* (0.75 mg in Europe) Ropinirole, 0.5-4.0 mg* Rotigotine, 1-3 mg/24 h	Nausea and orthostatic hypotension	Slowly increase dosage or use domperidone if available (10-30 mg).
	Insomnia	Add or switch to α2δ agent. Use a small dose of benzodiazepines in association with dopamine agonists.
	Daytime fatigue and somnolence	Reduce dosage or discontinue dopamine agonists.
	Compulsive or impulsive behavior	Reduce dose and add alternate medication class as needed. If significant, discontinue and change to alternate medication class.
	Tolerance	Discontinue and switch to longer-acting dopamine agonist or alternate medication class.
	Augmentation	Discontinue and switch to alternate medication class or longer-acting dopamine agonist.
Step 3: Dopamine Precursors		
Useful for intermittent treatment, such as twice a wk		
Levodopa-benserazide or levodopa-carbidopa (regular or slow release), 100/25 or 200/50 mg†	Same as for dopamine agonists	See countermeasures for dopamine agonists.
	Morning rebound or augmentation of restless legs syndrome in early evening	Use small extra dose of levodopa during daytime or reduce dosage or combine levodopa with dopamine agonists or benzodiazepines or discontinue levodopa (if severe and persistent).
	Augmentation	Do not use daily. Discontinue and switch to dopamine agonists or a nondopamine medication.
Benzodiazepines		
Useful for sleep promotion		
Clonazepam, 0.5-2.0 mg‡ Temazepam, 15-30 mg‡ Nitrazepam, 5-10 mg*	Daytime somnolence	Reduce dosage.
	Tolerance	Take drug holiday for 2 wk then return to lower dosage.
Opiates		
Second-line treatment		
Oxycodone-naloxone, 10/5 to 40/20 mg/day Methadone, 2.5-20 mg Oxycodone, 5-40 mg	Constipation	Use for symptom treatment.
	Dependency	Take a drug holiday. Discontinue and switch to alternate medication.
Oral Iron		
Always consider if serum iron ≤75 mcg/L *or* transferrin saturation ≤17%		
Ferrous sulfate, 650 mg (325 mg with vitamin C, 100 mg twice a day)	Constipation, stomach upset and pain	Reduce dose, discontinue, take with food.
	Diarrhea, nausea, vomiting	Reduce dose, discontinue, take with food.

*One hour before onset of symptoms in the evening or 1-2 hours before bedtime if symptoms are not present in the evening.
†Considered most appropriate for PRN dosing not more than 3 times a wk rather than daily use.
‡Before bedtime usually to promote sleep with restless legs syndrome.
From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.

- Rotigotine patch (Neupro) is also effective and FDA approved for moderate to severe RLS.
- Opiates, mostly methadone, are generally reserved as last line of treatment.
- Iron replacement should be started concurrently in case of iron deficiency. Iron supplements are indicated even with low-normal ferritin levels (<45 ng/ml). Sometimes IV iron replacement is used.

REFERRAL

Refer to neurologist if diagnosis is uncertain or an underlying disorder is suspected.

Retinal Detachment

BASIC INFORMATION

DEFINITION

Retinal detachment is the separation of the neurosensory retina (NSR) from the retinal pigment epithelium (RPE). This results in the accumulation of subretinal fluid (SRF) in the potential space between the NSR and the RPE. The main types of retinal detachment are **rhegmatogenous** (caused by retinal tear with vitreous fluid passing through the defect), **tractional** (subretinal fluid caused by fibrous proliferation and pulling from vitreous gel), and **exudative** (accumulation of subretinal fluid due to inflammation or tumors).

ICD-10CM CODES

H33	Retinal detachment and breaks
H33.2	Serous retinal detachment
H33.5	Other retinal detachments
H33.0	Retinal detachment with retinal break

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.) OF RHEGMATOGENOUS RETINAL DETACHMENT:

- Annual incidence roughly 1 in 10,000
- Particularly common in patients with high myopia of 5 diopters or more
- Incidence 1% to 2% after cataract surgery

PEAK INCIDENCE: Incidence increases with increasing age or increasing myopia

PREVALENCE (IN U.S.): Busy ophthalmologists may see one or two acute retinal detachments per month.

PREDOMINANT AGE:

- Most common age group is 40 to 70 yr old.
- Peak age coincides with peak incidence of acute posterior vitreous detachment, as this is the most important cause of a retinal tear.
- Rare in children and almost always due to congenital ocular disorders (Stickler syndrome) or trauma.

RISK FACTORS:

- Myopia
- Lattice degeneration (peripheral retinal thinning)
- Previous ocular surgery (particularly cataract surgery)
- Family history
- Contralateral retinal detachment or retinal tear
- Ocular trauma
- MEK inhibitors (serous retinal detachment)
- Ocular inflammation (uveitis)
- Retinal vascular disease (particularly diabetic retinopathy)
- Intraocular tumor (ocular or metastatic)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Sudden onset of flashes of light and floaters associated with a peripheral shadow or curtain
- May progress rapidly over days to involve central vision
- Generally no pain unless associated with ocular inflammation
- Examination reveals elevation of retina and vessels associated with tears in the retina () and/or hemorrhage in the vitreous

ETIOLOGY

- The overwhelming majority of retinal detachments are caused by a retinal tear or hole (rhegmatogenous) occurring after acute separation of the vitreous (posterior vitreous detachment [PVD]).
- Cataract surgery is thought to cause biochemical changes in the vitreous resulting in PVD.
- High myopia and lattice degeneration cause thin areas of the retina resulting in holes.
- Most common cause of traction RD is severe proliferative diabetic retinopathy resulting in fibrovascular proliferation with contraction of fibrous tissue and secondary detachment of retina.
- Ocular tumors and inflammation including posterior uveitis and scleritis are the most common causes of exudative retinal detachment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Degenerative retinoschisis
- Uveal effusion syndrome
- Choroidal detachment
- Hemorrhage
- Tumors

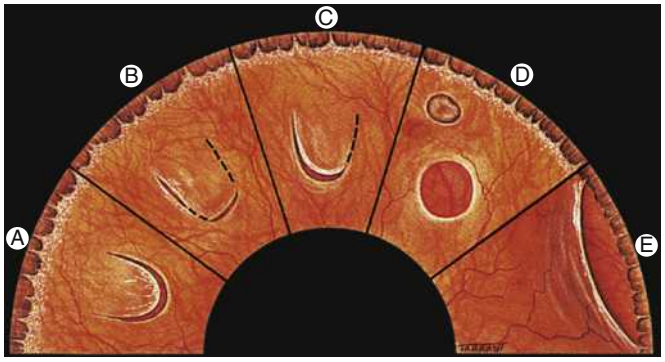

FIG. E1 Retinal tears. A, Complete U-shaped; **B,** linear; **C,** L-shaped; **D,** operculated; **E,** dialysis. (From Kanski JJ, Bowling B: *Clinical ophthalmology: a systematic approach,* ed 7, Philadelphia, 2010, Saunders.)

WORKUP

- Full eye examination with dilated fundus exam and retinal drawing to document tears and extent of detachment
- Visual fields
- Ultrasonography when the view of the fundus is limited due to hemorrhage or cataract to show the retinal detachment or tumors beneath it
- Medical workup only when inflammation or systemic disease considered

LABORATORY TESTS

Usually not necessary unless exudative detachment is being considered

IMAGING STUDIES

B scan ultrasonography (US) of the eye

TREATMENT

NONPHARMACOLOGIC THERAPY

Immediate surgery. The three principal methods for reattachment of the retina in patients with primary retinal detachment are scleral buckling, vitrectomy, and pneumatic retinopexy. There is a paucity of randomized trials comparing these procedures and the choice remains subjective. Some data suggest that vitrectomy may be preferable for detachment in pseudophakic eyes, whereas primary detachment in phakic eyes with complexity exceeding the original indications for pneumatic retinopexy may be treated with scleral buckling or vitrectomy.

ACUTE GENERAL Rx

- Early surgery to repair the detachment
- Treatment of the underlying disorder

CHRONIC Rx

Occasionally, steroids or other treatment of underlying inflammatory disease, if indicated

DISPOSITION

- Immediately refer to an ophthalmologist
- Early intervention improves outcomes

REFERRAL

Immediately

PEARLS & CONSIDERATIONS

COMMENTS

If treated early, most patients will recover a substantial portion of their vision.

AUTHOR: **Robert H. Janigian, Jr., MD**

Retinal Hemorrhage (PTG)

BASIC INFORMATION

DEFINITION

Retinal hemorrhages occur as a result of rupture of the rich retinal capillary network. The location of the vascular pathology determines the type of hemorrhage and may aid in the differential diagnosis. Preretinal hemorrhage usually implies neovascularization or traction, intraretinal hemorrhage is caused by rupture of capillaries or aneurysms within the retina, and subretinal hemorrhage occurs when there is rupture of choroidal vessels or subretinal neovascularization. Retinal hemorrhages are abnormal, and causes should be sought (see "Etiology").

SYNONYMS

Subretinal or preretinal hemorrhages
Splinter hemorrhage, dot and blot hemorrhages
Roth spots (small white centered blood, traditionally associated with endocarditis)

ICD-10CM CODES	
H35.60	Retinal hemorrhage, unspecified eye
H35.61	Retinal hemorrhage, right eye
H35.62	Retinal hemorrhage, left eye
H35.63	Retinal hemorrhage, bilateral

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Busy ophthalmologists see one or two cases a mo.
PREDOMINANT AGE: Usually vascular disease in older patients
PEAK INCIDENCE:

- In children: Associated primarily with trauma and hematologic disorders (must consider shaken baby syndrome and leukemia in every child with retinal hemorrhages), rare retinal vascular diseases of children (Coat syndrome, Eales disease)
- Associated with trauma, diabetes, vascular disease (hypertensive retinopathy, retinal vascular occlusions, sickle cell disease, anemia, radiation retinopathy), macular degeneration, altitude changes (mountain climbing)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Retinal hemorrhages in general do not cause loss of vision or ocular symptoms unless associated with other ocular pathology; symptoms, when present, are generally from the systemic cause.
- Ophthalmoscopy reveals hemorrhage within the retina, or on the nerve or subretinal area.
- Evidence of diabetes, hypertension, tumors, inflammation, macular degeneration, and drug use.

ETIOLOGY

- Vascular: Diabetic retinopathy, hypertensive retinopathy, retinal vein occlusion, carotid occlusive disease, Valsalva retinopathy, radiation retinopathy, retinal macroaneurysm, ischemic optic neuropathy
- Elevated intracranial pressure (hemorrhages generally located around or on optic nerve)
- Trauma
- Inflammatory diseases: Retinal vasculitis, lupus
- Infectious: HIV retinopathy, acute retinal necrosis (herpes virus mediated), endocarditis
- Neoplastic: Leukemia, vascular tumors of the retina, choroidal melanoma, metastatic tumors
- Degenerative diseases: Age-related macular degeneration, myopia, angioid streaks
- Rapid changes in altitude (mountain climbing or scuba diving)
- Drugs: Interferon, cocaine
- NOTE: In general, anticoagulants and antiplatelet drugs do not by themselves cause retinal hemorrhages

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Evaluate patients for local and systemic diseases (diabetes is most common).
- Trauma in children or adults.
- Venous or arterial occlusion associated with atherosclerotic heart disease may cause retinal hemorrhage.
- Rule out malignant melanoma, trauma, hypertensive, or cardiovascular disease.
- Section II describes the differential diagnosis of acute painless loss of vision.

WORKUP

- Complete history and general physical examination; evaluate for trauma; look for systemic diseases and medication etiologies
- Complete eye exam, including dilated fundus exam

LABORATORY TESTS

- Minimum: Complete blood count, erythrocyte sedimentation rate, complete blood chemistries
- Visual field testing

IMAGING STUDIES

- Color photography and fluorescein angiography (assess for retinal vascular causes, vasculitis, macular degeneration) (Fig. E1)
- Ocular ultrasound if tumor is in differential
- Carotid Doppler scan
- Trauma: Skull radiographs or head CT (evaluate for fractures)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Laser or treatment of underlying disorder
- Carotid endarterectomy if indicated

ACUTE GENERAL Rx

- Laser treatment may be indicated for certain retinal diseases (diabetic retinopathy, retinal vein occlusion, retinal macroaneurysm).
- Treatment may be indicated for wet macular degeneration or diabetic retinopathy (intravitreal injection).
- Treat underlying systemic disease.
- Repair any damage from trauma.

CHRONIC Rx

- Vitamin therapy: Age-Related Eye Disease Study 2 formulation for macular degeneration.
- Treatment will differ depending on various causes of bleeding.
- Treat medical problems (e.g., diabetes, hypertension).
- Encourage adequate control of underlying medical disorders.

DISPOSITION

If present, hemorrhage in the retina is generally considered abnormal; refer to ophthalmologist for evaluation.

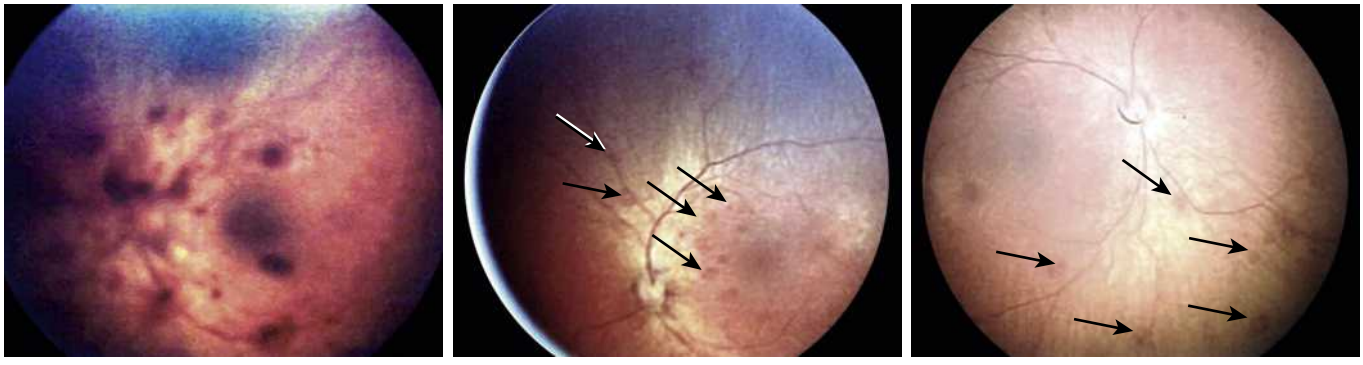

FIG. E1 Retinal hemorrhages. *Arrows* point to hemorrhages of various sizes. (From Kliegman RM [ed]: *Nelson textbook of pediatrics*, ed 19, 2011, Saunders.)

REFERRAL

Immediate referral to an ophthalmologist, especially if there is a significant change in vision or distorted vision; early treatment significantly affects outcome.

PEARLS & CONSIDERATIONS

COMMENTS

- Vision may not be affected if macula is not involved.
- Complete recovery of vision depends on cause.
- Chronic situations may have poor prognosis.

Retinitis Pigmentosa (PTG)

BASIC INFORMATION

DEFINITION

Retinitis pigmentosa (RP) refers to a group of phenotypically variable and genetically diverse retinal dystrophies resulting in predominantly rod photoreceptor cell death. Subsequent cone and retinal pigment epithelial involvement can also be seen. The term "retinitis" is a misnomer as inflammation plays a very minor role in the pathology. Visual manifestations usually include night blindness (nyctalopia) and loss of peripheral vision.

SYNONYM

RP

ICD-10CM CODE
H35.5 Hereditary retinal dystrophy

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (IN U.S.):
- Approximately 1 in 4000 in the U.S. and 1 in 5000 worldwide.
- It is the most commonly encountered hereditary fundus dystrophy.

PREDOMINANT SEX: X-linked presents only in males, but there is no gender predilection with the other genetic varieties.

PREDOMINANT AGE: Onset usually in young adulthood but can present at any time from infancy up to 30s to 50s, depending on mode of inheritance.

PEAK INCIDENCE:
- Autosomal recessive incidence: In the 20s
- Autosomal dominant form: In the 40s

GENETICS:
- Over 100 genetic loci have been mapped on more than 50 genes representing all inheritance patterns
- 20% autosomal recessive
- 10% to 20% autosomal dominant
- 10% X-linked
- Up to 40% have no family history and an unknown molecular genetic basis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Classic triad: Bone spicule and pigment clumping in the mid periphery (Fig. E1), "waxy pallor" of the optic nerve and arteriolar attenuation.
- Findings almost always bilateral but may be asymmetric.
- Other findings: Depigmentation and atrophy of retinal pigment epithelium (RPE), cataracts, and macular edema.
- Typical symptoms: Decrease in night vision and peripheral vision. Patients typically lose night vision to a greater extent than they lose day vision, and they lose peripheral vision before losing central vision.

ETIOLOGY

RP may occur as an isolated sporadic disorder, or may be inherited as autosomal dominant, autosomal recessive, or x-linked. Gene mutations that cause RP generally affect the biological function of the photoreceptors and RPE. The end result is photoreceptor apoptosis and cell death. XL is the least common but most severe form, and may result in complete blindness by the third or fourth decade.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Previous chorioretinitis: Syphilis, cytomegalovirus (CMV) retinitis, rubella, diffuse unilateral subacute retinitis
- Must consider other genetic disorders that cause retinal degeneration, including gyrate atrophy, choroideremia, Refsum disease, cone-rod dystrophy, cone dystrophy, and Leber congenital amaurosis
- Toxic retinopathies (phenothiazines, chloroquine)

WORKUP

- Electrophysiologic studies (electroretinogram results are most important)
- Dark adaptation studies
- Visual fields
- Medication history

LABORATORY TESTS

- Usually not necessary
- Venereal disease research laboratory (VDRL) if syphilis is a consideration
- Consider other conditions that cause pigmentary degeneration of the retina: Serum ornithine level or ornithine-lysine ratio (for gyrate atrophy of the retina and choroid) and serum phytanic acid level (for Refsum disease)

IMAGING STUDIES

- Color fundus photography
- Optical coherence tomography
- Fluorescein angiography

TREATMENT

CHRONIC Rx

- No proven therapy to prevent photoreceptor cell death.
- Nutritional and supplement therapy is controversial: High-dose vitamin A palmitate (15,000 IU) was shown to slow the decline of electroretinogram (ERG) response, but whether it translates to better visual prognosis is not clear.
- Docosahexaenoic acid (DHA), an omega-3 fatty acid thought to be important for photoreceptor function, has been evaluated in two clinical trials for its potential to slow vision loss in RP, but neither study showed a clear benefit.
- Based on clinical trial results, some experts recommend a regimen of 15,000 IU of vitamin A palmitate daily, lutein 12 mg daily, and two portions of oily fish weekly.
- Use of UV-absorbing sunglasses and brimmed hats for protection from high levels of light exposure seems prudent.
- Drugs that may negatively impact RP include isotretinoin (Accutane), sildenafil (Viagra), and vitamin E.
- Cystoid macular edema should be treated with carbonic anhydrase inhibitors including topical dorzolamide and acetazolamide, periocular or intravitreal steroid, and possibly intravitreal anti-vascular endothelial growth factor (anti-VEGF).
- Emerging therapies: Argus II retinal implant is a phototransducing chip that is surgically placed on the retinal surface and is FDA approved for RP patients with bare light perception or no light perception. Trials are

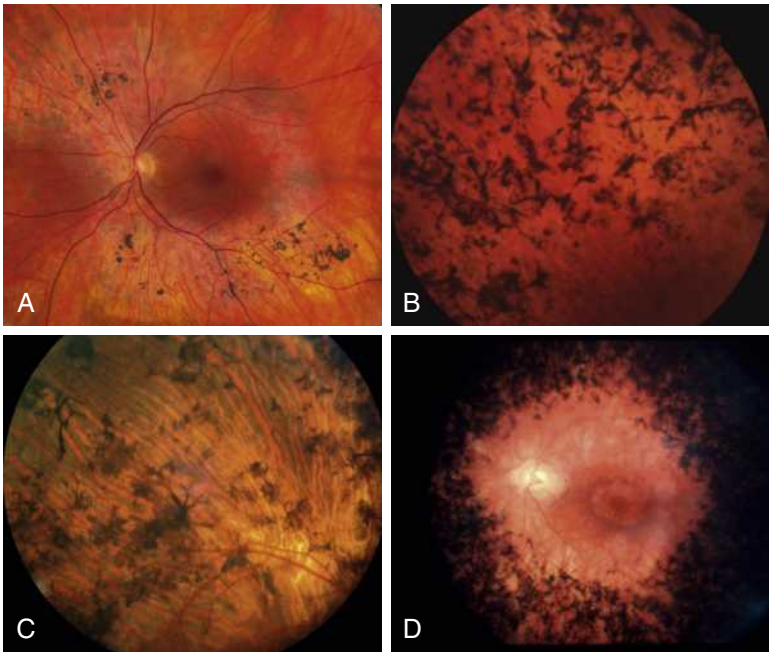

FIG. E1 Progression of retinitis pigmentosa. A, Early changes. **B,** Advanced changes. **C,** Unmasking of choroidal vessels. **D,** End-stage disease. (**A,** Courtesy P. Saine; from Kanski JJ, Bowling B. *Clinical ophthalmology: a systematic approach,* ed 7, Philadelphia, 2010, Saunders.)

under way using gene therapy targeted for specific gene mutations. Ciliary neurotrophic factor (CNTF) has been shown to slow retinal degeneration, and clinical trials are presently in progress.

DISPOSITION

- Reassurance that total blindness is rare; the overwhelming majority of patients maintain sight in one eye
- Low-vision evaluation
- Annual comprehensive eye examination with visual fields and possibly ERG every 2 yr
- Liver function studies for those on high-dose vitamin A

REFERRAL

To ophthalmologist to confirm diagnosis

PEARLS & CONSIDERATIONS

COMMENTS

- Patient education material can be obtained from the Retinitis Pigmentosa Foundation Fighting Blindness, 1401 Mt. Royal Avenue, 4th Floor, Baltimore, MD 21217.
- Information regarding ongoing clinical trials for RP can be found at clinicaltrials.gov.

BASIC INFORMATION

DEFINITION

Retinoblastoma is a congenital neoplasm arising from the neural layers of the retina. It represents the most common childhood intraocular malignancy and accounts for 10% to 15% of cancers occurring within the first yr of life.

ICD-10CM CODES

C69.20 Malignant neoplasm of unspecified retina
C69.21 Malignant neoplasm of right retina
C69.22 Malignant neoplasm of left retina

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Retinoblastoma affects 1 in 15,000 children, with approximately 300 children newly diagnosed each yr in the U.S. The worldwide incidence is 1 in 15,000 to 1 in 20,000 live births, constituting a total of 9000 new cases per yr. The annual incidence of retinoblastoma in children less than 15 yr was 4.1 per million between 2005 and 2009.

PEAK INCIDENCE:

- 6 to 13 mo. Mean age at diagnosis is 12 mo for bilateral tumors and 24 mo for unilateral tumors.
- 72% diagnosed by age 3.
- 90% diagnosed by age 4.

PREDOMINANT AGE: 8 mo

GENETICS:

- First disease demonstrating a genetic basis for cancer development:
  1. Biallelic inactivation of the *RB1* gene.
  2. Mutation of *RB1* gene predisposes to other second malignancies such as lung, bladder, bone, skin, or brain cancers.
- Either heritable or nonheritable, with the majority of cases having no positive family history:
  1. Heritable form affects one eye or both.
  2. Nonheritable form affects only one eye.
- Gene mutation or an autosomal-dominant gene with 80% to 95% penetration

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Leukocoria in a child <3 yr old (white reflex or white pupil) (Fig. E1)
- White elevated retinal masses
- Strabismus
- Glaucoma
- Uveitis
- Vitreous masses and opacity

ETIOLOGY

The retinoblastoma (*RB1*) gene is a tumor suppressor gene located on the long arm of chromosome 13 at region 14 that codes for the RB protein. A second genetic abnormality accountable for retinoblastoma has been discovered recently: the amplification of the *MYCN* gene. All bilateral retinoblastomas are heritable and often present at an earlier age. Biallelic *RB1* inactivation is responsible for most bilateral, heritable retinoblastomas. Of all retinoblastomas, ~60% are attributable to somatic, nonhereditary mutations caused by biallelic *RB1* loss. The *MYCN* gene amplification contributes a small percentage of nonheritable retinoblastoma with normal *RB1* gene.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Eye examination (Fig. E2):

- Strabismus
- Retinal detachment
- Uveitis
- Other tumors
- Glaucoma
- Coats disease (pathologic telangiectatic retinal vessels that leak and lead to accumulation of subretinal fluid and lipid)
- Endophthalmitis
- Cataract
- Infectious

SCREENING

Screening should be conducted shortly after birth with frequent follow-up by an ophthalmologist for children with a positive family history of retinoblastoma or 13q deletion.

WORKUP

Diagnosis is by ophthalmologic examination. An awake examination to determine if the patient can fixate, and extent of eye mobility should be done. Examination should also include visual acuity, papillary examination, extraocular movements, slit-lamp examination for evidence of iris neovascularization, hyphemia or hypopyon, indirect ophthalmoscopy with 360 degrees of scleral depression, and fundus photographs documenting all lesions. Ophthalmologic examination is followed by ultrasonography of the eye and MRI of the orbits and brain to exclude extraocular extension and trilateral retinoblastoma. Metastatic disease is rare at diagnosis, but if there is evidence of disease invasion into the optic nerve or extensive choroidal involvement, a full metastatic workup may be warranted, including lumbar puncture, bone marrow biopsy and aspirate, or radionuclide bone scan.

CLASSIFICATION

Several classifications for retinoblastoma have been in place for many yrs. In 1969, the Reese-Ellsworth classification system was devised to predict the outcome of external beam radiation. However, this classification became outdated as chemotherapy strategies became widely used for salvage therapy. In 2003, a new international classification system for intraocular retinoblastoma (IIRC) was formulated (Table E1). This system accurately reflects response to standardized chemotherapy regimen used in conjunction with focal consolidative therapy. The international classification system is subdivided into:

- Group A (small, very low risk)
- Group B (medium, low risk)
- Group C (confined, medium, moderate risk)
- Group D (diffuse, large, high risk)
- Group E (enucleation, advanced, very high risk)

STAGING

Table E2 summarizes the International Retinoblastoma Staging System.

IMAGING STUDIES

- MRI: May show calcifications in retina
- Ultrasonography: Good delineation of mass

TREATMENT

Usually treated by a multidisciplinary team consisting of a pediatrician, an ophthalmologist, a pediatric oncologist, and a pediatric radiation oncologist. Table E3 summarizes a recommended approach to the treatment of intraocular retinoblastoma. Treatment depends on location and stage of tumor when diagnosed:

- Chemotherapy was introduced in the 1990s and has shown efficiency in control of tumor growth in various stages of retinoblastoma. The goal of chemotherapy is to reduce the tumor volume for focal therapy with cryotherapy, laser, thermotherapy, or plaque brachytherapy. Systemic chemotherapy involves a three-drug regimen comprising vincristine, cisplatin, and etoposide
- Plaque brachytherapy with iodine-125 or ruthenium-106 and cryotherapy
- Surgical enucleation of the eye in heavy tumor burden; i.e., group E to prevent metastasis
- Radiation and chemotherapy

DISPOSITION

Overall there is a high cure rate (93% 5-yr survival in the U.S.) for retinoblastoma. Group A tumors generally have good visual and survival prognosis with focal consolidative therapy alone, groups B and C are treated with chemotherapy and focal therapy with good results (vision salvage rates up to 93%), group D patients often eventually require enucleation despite treatment.

REFERRAL

- To ophthalmologist, pediatric oncologist, and pediatric radiation oncologist.
- Prospective parents with a family history of retinoblastoma should be referred for genetic counseling. Genetic testing should be carried out for most retinoblastoma patients unless it is declined.

PEARLS & CONSIDERATIONS

COMMENTS

- High incidence of second tumor in survivors compared with general population
- High incidence of lung cancer, bladder cancer, and other epithelial cancers

TABLE E1 International Classification for Intraocular Retinoblastoma

GROUP A

Small tumors away from foveola and disc
- Tumors ≤3 mm in greatest dimension confined to the retina, and
- Located at least 3 mm from the foveola and 1.5 mm from the optic disc

GROUP B

All remaining tumors confined to the retina
- All other tumors confined to the retina not in group A
- Subretinal fluid (without subretinal seeding) ≤3 mm from the base of the tumor

GROUP C

Local subretinal fluid or seeding
- Local subretinal fluid alone >3 to ≤6 mm from the tumor
- Vitreous seeding or subretinal seeding ≤3 mm from the tumor

GROUP D

Diffuse subretinal fluid or seeding
- Subretinal fluid alone >6 mm from the tumor
- Vitreous seeding or subretinal seeding >3 mm from tumor

GROUP E

Presence of any of these poor-prognosis features:
- More than two thirds of globe filled with tumor
- Tumor in anterior segment
- Tumor in or on the ciliary body
- Iris neovascularization
- Neovascular glaucoma
- Opaque media from hemorrhage
- Tumor necrosis with aseptic orbital cellulitis
- Phthisis bulbi

TABLE E2 International Retinoblastoma Staging Systems

Stage 0: Patient treated conservatively
Stage I: Eye enucleated, completely resected histologically
Stage II: Eye enucleated, microscopic residual tumor
Stage III: Regional extension
a. Overt orbital disease
b. Preauricular or cervical lymph node extension
Stage IV: Metastatic disease
a. Hematogenous metastasis (without CNS involvement)
   1. Single lesion
   2. Multiple lesions
b. CNS extension (with or without any other site of regional or metastatic disease)
   1. Prechiasmatic lesion
   2. CNS mass
   3. Leptomeningeal and CSF disease

CNS, Central nervous system; *CSF,* cerebrospinal fluid.

BASIC INFORMATION

DEFINITION

Retroperitoneal fibrosis (RPF) is a condition characterized by the presence of inflammation and fibrosis surrounding the infrarenal aorta and iliac arteries. To make the diagnosis, the following must be present:

- A soft tissue density surrounding the infrarenal aorta or iliac vessels demonstrated on enhanced computed tomography (CT) or magnetic resonance imaging (MRI)
- Absence of a biopsy in the retroperitoneum that is positive for malignancy
- Absence of a systemic, multicentric, fibrosing process such as IgG4-related disease or a histiocytic disease such as Erdheim-Chester disease

SYNONYMS

Ormond disease (idiopathic retroperitoneal fibrosis)
Periureteritis fibrosa
Periureteritis plastic
Chronic periureteritis
RPF
Sclerosing retroperitoneal granuloma

ICD-10CM CODE

N13.58	Crossing vessel and stricture of ureter without hydronephrosis

EPIDEMIOLOGY & DEMOGRAPHICS

Patients with RPF present to medical attention in the fifth, sixth, and seventh decades of life with a mean age of 54 yr. There is a slight male-to-female predominance, with ratios ranging from 1:1 to 3:1 depending on the report. All races appear to be affected equally. Few epidemiological studies exist that accurately characterize the incidence and prevalence of the disease. One report from the Netherlands suggests an incidence of 0.10/100,000 individuals.

RISK FACTORS: Definitive risk factors for RPF have not been established. Associations with atherosclerosis of the abdominal aorta, therapeutic radiation exposure, asbestos exposure, and certain medications (methysergide, ergotamine, pergolide, cabergoline, bromocriptine) have all been associated with RPF.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The disease onset may be preceded by systemic symptoms such as fatigue, anorexia, and weight loss
- May take months from the time symptoms start until a specific diagnosis is established
- Dull, noncolicky pain that does not modify with position is present in the lower back, flank, and lower abdomen and radiates to the inguinal area
- Testicular pain may often be accompanied by a hydrocele or varicocele due to spermatic vein encasement
- New or worsening hypertension
- Acute kidney injury secondary to ureteral obstruction
- Lower extremity edema secondary to caval compression
- Deep venous thromboembolism or pulmonary embolus
- Hypothyroidism (secondary to autoimmune thyroiditis)
- Physical findings on exam include:
  1. Abdominal or flank tenderness
  2. Lower extremity edema
  3. Hydrocele
  4. New onset or worsening hypertension

ETIOLOGY & PATHOGENESIS

There is no formal agreement on the clinical definition of RPF. Likely, several different mechanisms exist to explain the evolution of this disease process. Unfortunately no animal model has been developed to further study this family of diseases, thus making elucidation of these mechanisms protracted. There are currently two different hypotheses proposed to explain the pathogenesis of RPF. The first model is based on the finding that many patients with RPF have a significant burden of atherosclerosis in the abdominal aorta. The incidence of this finding

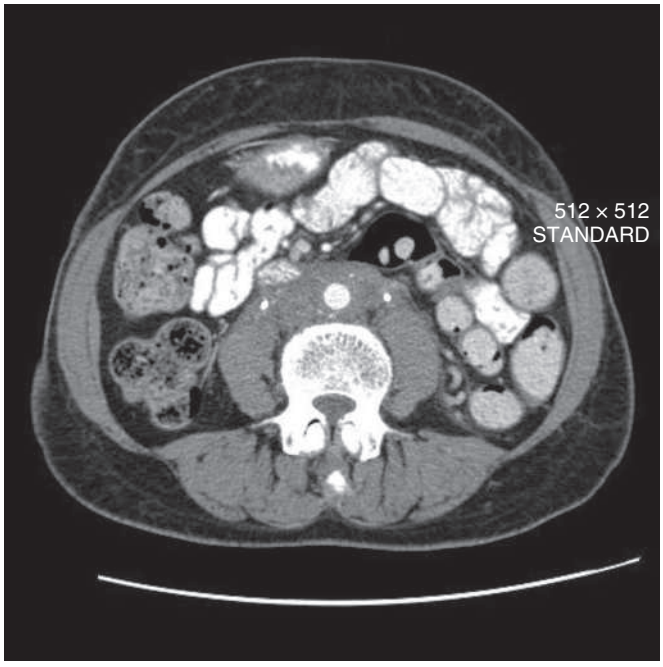

FIG. E1 Retroperitoneal fibrosis. Computed tomography scan of the abdomen with intravenous contrast reveals a soft tissue density surrounding the infrarenal aorta.

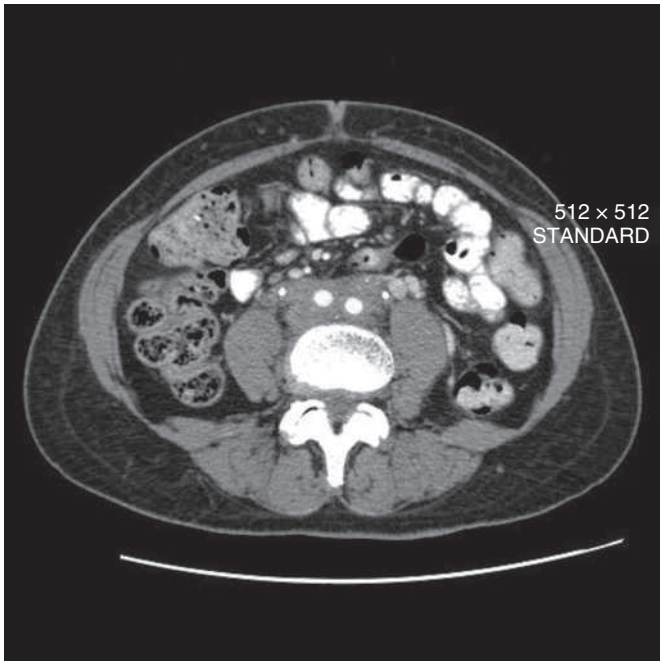

FIG. E2 Computed tomography scan of the pelvis reveals a soft tissue density surrounding the common iliac arteries.

varies by series. Other patients present with no evidence of an atherosclerotic burden, and alternative explanations have been proposed. Each may correctly explain a subset of patients with RPF, or components of each may uniformly apply to the broader heterogeneous population currently labeled as RPF.

1. Atherosclerosis model: This model was originally proposed by Michison and Parums in the mid-1980s. The authors noticed that the affected sections of the aorta had a heavy atherosclerotic burden. Microscopically the authors noted that the inflammatory reaction to the atherosclerosis was not limited to the intimal layer but expanded to the media and adventitial layers. The authors postulated that this "breach" into the media allowed lipid-laden macrophages to present oxidized low-density lipoprotein (LDL) and ceroid as antigens to T and B cells, thus initiating an immune reaction. This inflammatory reaction progressed to the adventitial layer and periaortic space, leading to the periaortitis and fibrosis.
2. These same authors could subsequently demonstrate that in patients with periaortitis, IgG could be shown to be in close apposition to extracellular ceroid. Additionally, they could show that ceroid-laden macrophages could be found in the adventitia and regional lymph nodes and that T and B cells found in the aorta media layer demonstrated markers of activation and proliferation. Finally, these authors showed evidence of elevated serum IgM and IgG antibodies to oxidized LDL and ceroid in patients with CP but not in a control population.
3. Autoimmune model: The evidence that RPF represents an autoimmune disease is broad but circumstantial. In one of his original papers, Ormond noted that the periaortic vessels in two of his patients resembled the vasculitis seen in polyarteritis nodosa. Similar findings of vasculitis of the vasa vasorum of the aorta have been documented by other authors. Moroni documented by flow cytometry that in patients with RPF there were increased numbers of circulating endothelial cells and that these cells were of microvascular origin. Similar findings were not found in patients with atherosclerosis or in healthy controls. These circulating endothelial cells returned to normal levels with suppression of the immune system. Vaglio has shown the presence of the HLA-DRB1* 03 allele in patients with RPF. This allele has also shown to be present in high numbers in other autoimmune diseases—namely, type 1 diabetes mellitus, myasthenia gravis, and systemic lupus erythematosus (SLE). Patients with RPF have been documented to also present with various other autoantibodies. There are also case reports of patients presenting with both RPF and with autoimmune diseases, such as seropositive inflammatory arthritis, ankylosing spondylitis, and SLE-associated and ANCA-associated vasculitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Retroperitoneal lymphoma
- Erdheim-Chester disease
- IgG-4 RD
- Metastatic breast cancer
- Inflammatory aortic aneurysm

WORKUP

- The initial diagnosis is usually made via CT scan or MRI. Definitive diagnosis is established by laparoscopic biopsy or ultrasound-guided percutaneous needle biopsy, but these are usually not required unless the diagnosis is in question
- Workup usually also involves:
  1. Age-appropriate cancer screening
  2. Cross-sectional imaging

LABORATORY TESTS

- An increase in the erythrocyte sedimentation rate (ESR) is almost always present.
- Elevated C-reactive protein (CRP). CRP and ESR lack sensitivity and specificity for the diagnosis of RPF.
- Serum creatinine is variably increased: present in 50% to 75% of patients.
- Anemia (normochromic, normocytic) present in 45% of patients.
- TSH is abnormal in 25% of patients.
- Antithyroperoxidase antibodies present in 24%.

IMAGING STUDIES

- Radiographic imaging usually provides a tentative diagnosis.
- Contrast-enhanced CT scan is the preferred imaging method and demonstrates a homogeneous, circumferential soft tissue mass surrounding the infrarenal abdominal aorta and common iliac arteries. Medial deviation of the ureters and inferior vena cava encasement are common.
- MRI shows low intensity on T1-weighted images and variable by T2-weighted images. Secondary cases due to malignancy are often not homogeneous, are bulky, and less often cause medial ureteral deviation.

BIOPSY

The pathology of RPF is that of a fibroinflammatory disease marked by chronic inflammation and fibrous tissue. The inflammatory infiltrate consists of lymphocytes, plasma cells, and rare macrophages. Lymphoid aggregates contain T and B cells. If the ratio of IgG-4 to total IgG is >40%, consider IgG-4–related disease.

TREATMENT

GOALS OF TREATMENT

- Identify and discontinue the use of any inciting or suspected drug
- Suppress inflammatory process
- Preserve renal function by maintaining ureteral patency
- Exclude malignancy
- Relieve symptoms

NONPHARMACOLOGIC THERAPY

Therapy is initially directed toward drainage of the ureteral obstruction by a ureteral stent or percutaneous nephrostomy tube.

ACUTE GENERAL Rx/CHRONIC Rx

- The aim of pharmacologic treatment is to reduce or eliminate the inflammatory soft tissue mass. There are multiple approaches to medical therapy. The two most commonly used medical protocols are the following:
  1. Glucocorticoids are the initial immunosuppressant used, with doses of 0.75 to 1 mg/kg/day prednisone tapered over the 6 to 9 months.
  2. Mycophenolate mofetil 1000 mg by mouth twice daily with corticosteroids, starting at 40 mg per day, with a taper of 10 mg per month. After prednisone 10 mg daily has been taken for 1 month, reduce to 5 mg daily for 30 days and then discontinue prednisone. Mycophenolate mofetil is continued until ureteral stents or PCN have been removed for 6 months, with no evidence of recurrent obstruction. Mycophenolate mofetil is continued for 6 months in cases in which no obstruction is present for at least 6 months and after a 25% reduction in the periaortic mass.
  3. Although tamoxifen had historically been used as a steroid-sparing agent, randomized clinical trials have shown it to be of less benefit than prednisone.
  4. A randomized trial of prednisone alone versus prednisone plus mycophenolate mofetil has not been conducted. Both regiments report excellent response rates.

STENT MANAGEMENT

For patients with unilateral or bilateral stents in which cross-sectional imaging demonstrates a reduction of the periaortic or peri-iliac mass and in which the effected ureter(s) is free from the fibroinflammatory density, only one stent should be removed at a time.

After removal, patients are assessed for increased pain and decreased urine output. At 48 hr, blood is obtained for analysis of creatinine and potassium. If there is no clinical suspicion of obstruction, a technetium-99m nuclear scan with furosemide washout is obtained at 14 days. If excretion is normal ($T_{1/2}$ excretion, <12 min), the contralateral stent may be removed. At day 14, a partial obstruction may exist from ureteral edema. If a partial obstruction is demonstrated at day 14 ($T_{1/2}$ excretion, 12 to 20 minutes), the examination is repeated in 2 weeks. If a partial obstruction still exists, the ureteral stent is replaced. If the follow-up study indicates no obstruction, the stent can remain out and attention to remove the contralateral stent, if present, with a simi-

lar protocol proceeds. For patients in whom ureteral obstruction was relieved with a percutaneous nephrostomy and cross-sectional imaging suggests regression of the mass sufficient to relieve the obstruction, patency may be evaluated by closing the external stopcock and proceeding with a technetium-99m nuclear scan with furosemide washout, as described previously, or by formal Whittaker manometry.

DISPOSITION

- Long-term follow-up is required because of the potential for disease recurrence.
- After discontinuation of medications, renal function, inflammatory markers (e.g., erythrocyte sedimentation rate), and complete blood count are followed monthly for 6 months and quarterly afterward.
- Cross-sectional imaging by CT or MRI is performed 6 months after discontinuation of medications.
- For patients with normal labs and normal cross-sectional imaging at 6 months, annual follow-up is appropriate, unless new symptoms occur.
- Prognosis is usually good; however, if RPF chronically relapses, maintenance therapy and monitoring are required.

BASIC INFORMATION

DEFINITION

Retropharyngeal abscess is a soft tissue infection of the throat that involves retropharyngeal space and that primarily affects children. The anatomic boundaries of the retropharyngeal space are the buccopharyngeal fascia (middle layer of the deep cervical fascia) anteriorly and the alar fascia (deep layer of the deep cervical fascia) posteriorly. The space begins at the skull base superiorly and ends inferiorly where the two fasciae fuse at the level between the first and second thoracic vertebrae.

ICD-10CM CODE

J39.0 Retropharyngeal and parapharyngeal abscess

EPIDEMIOLOGY & DEMOGRAPHICS

Retropharyngeal abscess occurs most commonly in children between the ages of 2 and 4 yr, analogous to suppurative cervical adenitis. 70% of cases are in patients under the age of 6, and 50% are in patients under the age of 3. This represents the peak age group for numerous viral upper respiratory tract infections and their attendant complications, acute otitis media and sinusitis. Retropharyngeal space infection is less common in older children and adults because the lymph nodes generally atrophy by puberty.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The onset of a retropharyngeal infection may be insidious, with little more than fever, irritability, drooling, a muffled voice (dysphonia), or possibly nuchal rigidity.
- The acute symptoms relate to pressure and inflammation produced by the abscess on either the airway or the upper digestive tract and pharynx. The patient may have intense dysphagia, drooling, and odynophagia, or there may be some element of respiratory distress from edema and inflammation of the airway (stridor, tachypnea, or both).
- Unwillingness to move the neck because of discomfort is often a prominent presenting feature and should lead to consideration of retropharyngeal abscess if the child is febrile and irritable.
- Extension of the neck is usually affected more than flexion. This causes the patient to hold his or her neck stiffly or to present with torticollis.
- Trismus is unusual.
- On physical examination it may be possible to appreciate midline or unilateral swelling of the posterior pharyngeal wall. The mass may be fluctuant to the examining finger, and care must be taken to avoid rupture of the abscess into the upper airway.

Complications are numerous and could be fatal; these include airway obstruction, septicemia, thrombosis of the internal jugular vein, carotid artery rupture, and acute necrotizing mediastinitis. Aspiration with resultant pneumonia may complicate retropharyngeal abscess if rupture of the abscess occurs and empties into the airway. Infection can spread from one space in the neck to another.

The most dreaded complication is jugular vein suppurative thrombophlebitis (Lemierre syndrome), in which the vessels of the carotid sheath become infected, leading to bacteremia and spread of infection to the lungs, brain, and mediastinum.

ETIOLOGY

- The retropharyngeal space comprises two chains of lymph nodes that drain the nasopharynx, adenoids, posterior paranasal sinuses, middle ear, and Eustachian tube. Accordingly, suppurative infections in these areas may provide the seeds for infection for retropharyngeal abscess.
- The predominant bacterial species are *Streptococcus pyogenes* (group A *Streptococcus*), *Staphylococcus aureus,* and respiratory anaerobes (including *Fusobacteria, Prevotella,* and *Veillonella* species). *Haemophilus* species are also occasionally found.
- In young children, infection usually reaches this space by lymphatic spread from a septic focus in the pharynx or sinuses.
- In adults, infection may reach the retropharyngeal space from either local or distant sites. Penetrating trauma (e.g., from chicken bones or iatrogenic) is the usual source of local spread. More distant sources of infection include odontogenic sepsis and peritonsillar abscess (now a rare cause).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cervical osteomyelitis
- Pott disease
- Meningitis
- Calcific tendonitis of the long muscle of the neck
- Differentiating features of deep neck infections are summarized in Table 1

LABORATORY STUDIES

- CBC with differential.
- Blood cultures may be considered in refractory cases or for severe symptoms.

IMAGING STUDIES

- A lateral neck film should be obtained and can be helpful in delineating the presence of a retropharyngeal abscess and may demonstrate cervical lordosis; the retropharyngeal space is considered widened and pathologic if it is greater than 7 mm at C2 or 14 mm at C6 (Fig. E1).
  1. There must be attention to technical issues when performing the study, especially in children. The film should be a perfect lateral, and the child must keep the neck in extension during inspiration to avoid a false thickening of the retropharyngeal space. Crying, particularly in infants, may also cause false thickening of the retropharyngeal space.
- CXR should be considered to evaluate for mediastinitis or aspiration pneumonia.
- A CT scan of the neck is useful for patients with moderate or high suspicion of having a deep neck space abscess. It is the most useful imaging modality to identify abscesses in the retropharyngeal space, but it is not perfect. Both the sensitivity and specificity of the CT scan in predicting the presence of drainable purulent material are quite variable from study to study, ranging between 68% and 100%.
  1. The CT scan provides more information than the plain radiograph because it can generally differentiate between retropharyngeal cellulitis and retropharyngeal abscess and can demonstrate extension of the retropharyngeal abscess to contiguous spaces in the neck. Findings

TABLE 1 Differentiating Features of Deep Neck Infections

Space	Clinical Features*
Submandibular space (Ludwig angina)	Woody submental induration, protruding swollen/necrotic tongue, no trismus, rotted lower molars commonly present
Lateral pharyngeal space (anterior)	Fever, toxicity, trismus, neck swelling
Lateral pharyngeal space (posterior)	No trismus, no swelling (unless ipsilateral parotid is involved), cranial nerve IX-XII palsies, Horner syndrome, carotid artery erosion
Retropharyngeal space (retropharynx)	Neck stiffness, decreased neck range of motion, soft-tissue bulging of posterior pharyngeal wall, sore throat, dysphagia, dyspnea
Retropharyngeal space ("danger space")	Mediastinal or pleural involvement
Retropharyngeal space (prevertebral)	Neck stiffness, decreased neck range of motion, cervical instability, possible spread along length of vertebral column
Jugular vein septic thrombophlebitis (Lemierre syndrome)	Sore throat, swollen tender neck, dyspnea, chest pain, septic arthritis

*Fever and signs of systemic toxicity are common to all.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

TABLE 2 Therapeutic Options for Deep Neck Infections

Syndrome	Likely Flora	Therapeutic Options*
Submandibular space infection (community acquired)	Anaerobes, streptococci, *Staphylococcus aureus*	Ampicillin-sulbactam (3 g IV q6h) Ceftriaxone (1-2 g IV q24h) *plus* clindamycin (300-900 mg IV q8h) *or* metronidazole (500 mg IV q6h) Ertapenem (1 g IV q day)
Submandibular space infection (hospital/ICU acquired)	*Pseudomonas aeruginosa,* methicillin-resistant *S. aureus* (MRSA), anaerobes	Imipenem (500 mg IV q6h) *or* piperacillin-tazobactam (3.375 g IV q8h by continuous infusion) *plus* vancomycin (1 g IV q12h)
Retropharyngeal space infection	Anaerobes, streptococci, *S. aureus*	Ampicillin-sulbactam (3 g IV q6h) Ceftriaxone (1-2 g IV q24h) *plus* clindamycin (300-900 mg IV q8h) *or* metronidazole (500 mg IV q6h) Ertapenem (1 g IV q day)
Lateral pharyngeal space infection	Anaerobes, streptococci, *S. aureus*	Ampicillin-sulbactam (3 g IV q6h) Ceftriaxone (1-2 g IV q24h) *plus* clindamycin (300-900 mg IV q8h) *or* metronidazole (500 mg IV q6h) Ertapenem (1 g IV q day)
Internal jugular vein septic thrombophlebitis	*Fusobacterium necrophorum*	Metronidazole (500 mg IV q6h) Clindamycin (300-900 mg IV q8h) Ampicillin-sulbactam (3 g IV q6h)

ICU, Intensive care unit; *IV,* Intravenous.
*Antibiotic choices listed are examples, because for most infections, multiple different antibiotics are effective; individual choice will be influenced by patient factors (e.g., allergies, concurrent medications), local hospital bacterial resistance rates, and microbiological culture results.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

on CT common to both cellulitis and abscess are a low-density core, soft tissue swelling, obliterated fat planes, and mass effect. Findings on CT scan that are indicative of abscess are "complete rim enhancement" and scalloping of the abscess borders (Fig. E2). The abscess may be seen as a mass impinging on the posterior pharyngeal wall.

- MRI of the neck is rarely used for diagnosis, especially in the pediatric population because of the longer time to acquire the study and the need for sedation in the younger population. T2-weighted images may identify and localize areas of pus for drainage or aspiration. Gadolinium enhancement is important to accurately define the soft tissue component. It also can be useful for distinguishing inflammatory from congenital or neoplastic lesions. Magnetic resonance angiography can be helpful for imaging vascular lesions, such as jugular thrombophlebitis.

Rx TREATMENT

ACUTE GENERAL & CHRONIC Rx

- When the CT findings suggest cellulitis or phlegmon, a trial of IV antibiotic therapy without drainage is initiated, and the child is monitored as an inpatient for 48 hr. If the child is clinically improved, consider discharge home with a course of oral antibiotics. If the clinical course is not improved or is worse, a repeat CT scan should be obtained, and surgical drainage or prolonged IV antibiotic therapy may be warranted. Some investigators also support a trial of IV antibiotic therapy alone when small abscesses are identified by CT scans, as long as the airway is not compromised.
  1. Ampicillin-sulbactam (300 mg/kg/day IV divided q6h) or clindamycin (25 to 40 mg/kg/day IV divided q8h) are effective antimicrobial selections. In adults, ampicillin-sulbactam 3 g IV q6h or clindamycin 600 mg IV q8h. Antibiotics should be adjusted as culture data become available, and oral therapy is continued to complete at least a 14-day course. Therapeutic options for deep neck infections are summarized in Table 2.
- Surgical intervention has historically played a prominent role in the management of retropharyngeal abscess in conjunction with antibiotic therapy. Prompt surgical drainage is indicated when there is a large hypodense area suggestive of an abscess or when a patient has not responded to parenteral therapy alone.

PEARLS & CONSIDERATIONS

PREVENTION

The complications of deep neck infection in any space are numerous and potentially fatal. Early diagnosis, with prompt and appropriate management, is key to avoiding these complications.

Reye Syndrome

BASIC INFORMATION

DEFINITION

Reye syndrome is a postinfectious triad consisting of encephalopathy, fatty liver degeneration, and transaminase elevation.

ICD-10CM CODE
G93.7 Reye syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- During the 1970s, 300 to 600 cases were being reported yearly in the U.S.
- Since the mid-1980s, after the understanding that aspirin is associated with Reye syndrome, the yearly count has fallen to <20 cases.
- Seasonal relation with influenza and varicella outbreaks.
- Age: Rare in persons aged >18 yr; peak age (in the U.S.) is 6 to 8 yr.
- Case-fatality rate: 25% to 50%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Shortly after recovery from a viral infection (flu or chickenpox), an afebrile child begins to vomit intractably. Hepatomegaly is often present. The vomiting can lead to dehydration. Occasionally, symptoms of hypoglycemia are present. After 2 days symptoms of encephalopathy dominate the clinical picture (lethargy, confusion, stupor, coma, seizures, decorticate or decerebrate posture) (Table E1).

ETIOLOGY

- Temporal association with influenza and varicella infection
- Epidemiologic association with aspirin or other salicylate use to treat the viral infection
- Possible association with aflatoxin and pesticides
- Pathology
- Liver: No inflammation; the striking finding is panlobular microvesicular hepatocyte infiltration on light microscopy and mitochondrial injury on electron microscopy
- Brain: No inflammation but cerebral edema and anoxic degeneration
- Pathogenesis: Not fully understood but mitochondrial dysfunction is clearly center stage

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inborn errors of metabolism (e.g., carnitine deficiency, ornithine transcarbamylase deficiency)
- Salicylate or amiodarone intoxication
- Jamaican vomiting sickness
- Hepatic encephalopathy of any cause

Table E2 describes diseases that present a clinical or pathologic picture resembling Reye syndrome.

TABLE E2 Diseases That Present a Clinical or Pathologic Picture Resembling Reye Syndrome

Metabolic disease:
Organic aciduria
Disorders of oxidative phosphorylation
Urea cycle defects (carbamoyl phosphate synthetase, ornithine transcarbamylase)
Defects in fatty acid oxidation metabolism
Acyl-CoA dehydrogenase deficiencies
Systemic carnitine deficiency
Hepatic carnitine palmitoyltransferase deficiency
3-OH, 3-methylglutaryl-CoA lyase deficiency
Fructosemia
Central nervous system infections or intoxications (meningitis), encephalitis, toxic encephalopathy
Hemorrhagic shock with encephalopathy
Drug or toxin ingestion (salicylate, valproate)

CoA, Coenzyme A.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

WORKUP

According to the Centers for Disease Control and Prevention (CDC) case definition, the following conditions must be met for consideration as a Reye syndrome case:

- Acute noninflammatory encephalopathy documented by:
  1. Alteration in the level of consciousness and, if available, a record of cerebrospinal fluid containing ≤8 leukocytes per mm^3 or
  2. Histologic specimen demonstrating cerebral edema without perivascular or meningeal inflammation
- Hepatopathy documented either by a liver biopsy or autopsy considered to be diagnostic of Reye syndrome or by a threefold or greater rise in the levels of serum aspartate aminotransferase, serum alanine aminotransferase, or serum ammonia
- No more reasonable explanation for the cerebral and hepatic abnormalities

LABORATORY TESTS

- Elevated transaminase (alanine aminotransferase and aspartate aminotransferase)
- Elevated ammonia level
- Occasional elevation of creatine phosphokinase, lactate dehydrogenase, and bilirubin and prolongation of prothrombin time
- Occasional hypoglycemia (in patients <4 yr)
- Cerebrospinal fluid is normal or contains <8 white blood cells per milliliter
- Rarely a liver biopsy is indicated (in infants or in recurrent cases)

TREATMENT

- Supportive
- Mannitol, glycerol, or hyperventilation for cerebral edema if present
- Interferon-alfa (experimental)
- Prevention:
  1. Influenza vaccine
  2. Varicella vaccine
  3. Avoidance of aspirin in children, especially during influenza and varicella outbreaks

TABLE E1 Clinical Staging of Reye Syndrome

Grade	Symptoms at Time of Admission
I	Usually quiet, **lethargic** and sleepy, vomiting, laboratory evidence of liver dysfunction
II	Deep lethargy, **confusion,** delirium, combative, hyperventilation, hyperreflexic
III	Obtunded, **light coma,** seizures, decorticate rigidity, intact pupillary light reaction
IV	Seizures, deepening coma, **decerebrate rigidity,** loss of oculocephalic reflexes, fixed pupils
V	Coma, loss of deep tendon reflexes, respiratory arrest, fixed dilated pupils, **flaccidity/decerebrate** intermittent isoelectric electroencephalogram

From Behrman RE: *Nelson textbook of pediatrics,* ed 17, Philadelphia, 2005, Saunders.

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Rhesus (Rh) incompatibility is a clinical scenario where discordance of the maternal and fetal Rh type leads to the development of maternal Rh sensitization and hemolytic disease of the neonate. Individuals whose RBCs express the Rh D antigen are classified as Rh-positive, whereas those whose RBCs do not express the antigen are classified as Rh-negative.

ICD-10CM CODES

036.0910	Maternal care for other rhesus isoimmunization, first trimester, not applicable or unspecified
T80.4	Rh incompatibility reaction
T80.4	Unspecified complication following infusion, transfusion, and therapeutic injection

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- The absence of the D antigen (Rh negative blood type) occurs in 15% to 17% of Caucasians, 4% to 8% of blacks, and <1% of the Native American and Asian populations. If the father's blood type is not known, the chance that an Rh– pregnant woman is bearing an Rh+ fetus is approximately 60%.
- Of those pregnancies complicated by Rh incompatibility, the risk of maternal isoimmunization to the D antigen is approximately 8% for each ABO-compatible pregnancy if no prophylaxis is given.
- Maternal-fetal ABO incompatibility is somewhat protective against Rh isoimmunization.

GENETICS: Five major loci determine Rh status: C, D, E, c, e. The presence of the D antigen results in an Rh+ individual, while its absence results in an Rh– individual. Of Rh+ fathers, 45% are homozygotes, and 55% are heterozygotes. For homozygous Rh+ fathers, the probability of an Rh+ offspring is 100%. The probability for heterozygotes is approximately 50%.

RISK FACTORS:

- RhD-negative woman
- Antepartum: Fetal-to-maternal transfusion
- Intrapartum: Fetal-to-maternal transfusion, spontaneous abortion, ectopic pregnancy, abruptio placentae, abdominal trauma, chorionic villus sampling, amniocentesis, percutaneous umbilical blood sampling (PUBS), external cephalic version, manual removal of the placenta, therapeutic abortion, autologous blood product administration
- Maternal history of hydrops or sensitization to RhD

ETIOLOGY

The initial response to D antigen exposure is production of immunoglobulin (Ig) M that does not cross the placenta. With a repeated exposure, IgG is produced. Hemolysis in the fetus results once maternal IgG is present in the fetal circulation by crossing the placenta. This may result in a spectrum of hemolytic disease in the newborn, resulting in antepartum or neonatal death or neurologic damage to the fetus because of hyperbilirubinemia and kernicterus.

DIAGNOSIS

LABORATORY TESTS

ABO and Rh blood type and an antibody screen as part of the initial prenatal profile.

- If antibody screen negative:
  1. Repeat antibody screen at 28 weeks of gestation.
  2. Obtain neonatal blood type after delivery.
  3. If Rh incompatibility is confirmed by the neonatal blood type, a Kleihauer-Betke/flow cytometry or rosette test should be performed to determine the amount of fetomaternal transfusion in the following high-risk circumstances: abruptio placentae, placenta previa, cesarean delivery, intrauterine manipulation, manual removal of the placenta.
- If anti-D antibody screen is positive:
  1. Maternal indirect Coombs test is needed to determine antibody titer.
  2. Determine paternal Rh status and zygosity.
  3. If father is heterozygous, PUBS or amniotic fluid is needed to determine fetal Rh status.

IMAGING STUDIES

- Ultrasound evaluation may show subcutaneous edema, ascites, pleural effusion, pericardial effusion, or hepatomegaly. It can diagnose hydrops fetalis, but it cannot predict it.
- Doppler ultrasound of middle cerebral artery can predict moderate to severe anemia.

TREATMENT

PREVENTION OF D-ISOIMMUNIZATION

- 50 mcg of D immunoglobulin: After spontaneous or induced abortion or ectopic pregnancy <13 weeks' gestation
- 300 mcg of D immunoglobulin (protects against 30 ml of fetal blood)
  1. After spontaneous or induced abortion >13 weeks' gestation, amniocentesis, chorionic villous sampling, PUBS, external cephalic version, or other intrauterine manipulation
  2. As antepartum prophylaxis at 28 weeks' gestation. Maternal anti-D prophylaxis does not cause hemolysis in the fetus or newborn
  3. At 40 weeks' gestation or at delivery if the neonate is D- or Du-positive
  4. If Kleihauer-Betke or rosette test confirms >30 ml of fetal red blood in maternal circulation, additional D immunoglobulin is indicated. Confirm adequacy of therapy by a maternal indirect Coombs test 48 to 72 hr after Rh immunoglobulin is given

MANAGEMENT OF D-ISOIMMUNIZED PREGNANCIES

- Serial amniocentesis for assessment of amount of fetal bilirubin in fluid (OD_{450}) after 25 weeks' gestation with interpretation of the Delta OD_{450} according to criteria established by Liley
- PUBS if ultrasonographic evidence of hydrops, rising zone II Delta OD_{450} values on amniocentesis, or maternal history of a severely affected child
- Intrauterine exchange transfusion if severe anemia is documented remote from term
- Initiation of steroids for lung maturation at 28 weeks in severely affected pregnancies with delivery at lung maturity
- Delivery as soon as lung maturation is achieved in mild to moderately affected pregnancies

Fig. 1 shows an algorithm for clinical management of a patient with red cell sensitization in the first affected pregnancy and Fig. 2 shows an algorithm for clinical management of a patient with red cell sensitization and a previously affected fetus or infant.

DISPOSITION

Survival of nonhydropic infants is 90%. Of infants with hydrops, 82% survive.

REFERRAL

Refer all Rh isoimmunized pregnancies to a tertiary care center before 18 to 20 weeks of gestation.

BASIC INFORMATION

DEFINITION

Rhabdomyolysis is a syndrome characterized by striated muscle lysis with resulting muscle damage and leakage of intracellular contents into the circulation. The presentation may range from asymptomatic elevation of creatine kinase (CK) to severe muscle injury with irreversible kidney failure. In general, five- to tenfold elevations of CK levels, muscle pain, and myoglobinuria in an appropriate clinical setting (see below) are sufficient criteria for the diagnosis of rhabdomyolysis. Acute renal injury occurs from a combination of factors, including volume depletion, tubular obstruction, direct heme-induced proximal tubular cell injury, and associated renal vasoconstriction.

ICD-10CM CODES

M62.82	Rhabdomyolysis (idiopathic)
T79.6	Traumatic ischemia of muscle
M62.89	Other specified disorders of muscle

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT AGE: Incidence of 1 in 10,000 in the U.S.

- Rare in children. Increased risk with advanced age, i.e., >80 yr
- Reported incidence of AKI with rhabdomyolysis is 10% to 55%
- 7% to 10% of cases of AKI are due to rhabdomyolysis

MORTALITY RATE: 5% to 8%. Prognosis is better in the absence of AKI.

ONSET: Evidence is limited regarding the onset of physical exertion-induced rhabdomyolysis. Exercise levels exceeding usual exercise tolerance levels for individuals are commonly causative. Extracellular volume depletion and vasoconstriction are common predisposing features. Patients with risk factors (e.g., metabolic myopathies, advanced age) develop symptoms associated with rhabdomyolysis within 2 to 6 hr after activity. Patients without such risk factors generally become symptomatic 12 to 36 hr after muscle injury. The presence of concurrent electrolyte abnormalities such as hypokalemia, hyponatremia, hypernatremia, hypomagnesemia, hypophosphatemia, and hypocalcemia increases the risk for rhabdomyolysis.

CK levels rise within 2 to 12 hr of the onset of muscle injury, peak generally by 24 to 72 hr, and decline within 3 to 5 days after cessation of muscle injury. Peak CK concentrations may predict development of renal injury. In patients with rhabdomyolysis secondary to malignant hyperthermia, CK concentrations peak approximately 14 hr after an acute episode.

Cholesterol-lowering therapy with HMG-CoA synthetase inhibitors (statins) in association with severe clinical rhabdomyolysis requiring hospitalization is reported in less than 0.1% of cases, although myalgia is a frequent complaint. Studies have demonstrated that glycolytic skeletal muscles have a low antioxidant defense, which limits their potential for metabolizing reactive oxygen species (ROS) leading to damage of muscle cells. The mechanism by which this occurs is multifactorial: uptake efficacy of transport proteins in hepatocytes, level of systemic circulation of statins, level of extrahepatic inhibition of mitochondrial respiration, bioavailability, and lipophilicity. Among the statins, pravastatin has been reported to have a lower risk of rhabdomyolysis, presumably due to its lower lipid solubility. The average duration of statin therapy before the onset of myopathy is 6 mo. Symptom resolution with normalization of serum CK concentrations occurs in days to weeks following drug discontinuation. The average time for onset of rhabdomyolysis after addition of fibrate to statin therapy is 32 days. There are very rare genetic variants associated with statin-induced myopathy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Classic triad: (1) Muscle pain, (2) weakness, and (3) dark urine from myoglobinuria
- Muscle tenderness is present only 50% of the time
- Muscle swelling
- Muscular rigidity
- Fever
- Altered consciousness
- In statin-induced rhabdomyolysis, fatigue (74%) is nearly as common as muscle pain (88%)
- Oliguria or anuria in the presence of kidney injury

ETIOLOGY

Causes can be divided into three categories:

- Traumatic or muscle compression:
  1. High-current electrical injury
  2. Crush injury and compartment syndrome
  3. Tourniquet and limb ischemia
  4. Reperfusion after revascularization procedures for ischemia
  5. Extensive surgical (spinal) dissection, bariatric surgery
- Nontraumatic exertional:
  1. Exercise: More than 10 genetically predisposing mutations are associated with exertional rhabdomyolysis
  2. Sickle cell trait, rarely; usually additional predisposing factors are involved (e.g., BMI >30 kg/m^2, tobacco use, statin use, antipsychotic use, high altitude)
  3. Heat stroke
  4. Metabolic myopathies
  5. Malignant hyperthermia and neuroleptic malignant syndrome
  6. Seizure activity
- Nontraumatic, nonexertional:
  1. Drug-induced (statins alone, combination of statins with fibrates, or erythromycin, simvastatin and amiodarone, amphetamines, haloperidol, levofloxacin, macrolide antibiotics)
  2. Alcoholism
  3. Hypothyroidism
  4. Infectious and inflammatory myositis

Table 1 summarizes the various causes of rhabdomyolysis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

"Creatine Kinase Elevation" in Section IV describes a clinical algorithm for the evaluation of CK elevation.

LABORATORY TESTS

- Creatine kinase: Usually CK is 5 to 10 times the upper limit of normal and typically peaks 24 to 72 hours after the initial insult (Fig. 1). Levels >15,000 IU/L are more likely to be associated with renal injury. However, in patients with concomitant risk factors such as hypokalemia or volume depletion, CK levels as low as 5000 U/L have been associated with AKI.
- Myoglobin: Excreted in urine with visible changes in urine ("port wine") at levels >100 to 300 mg/dl. Myoglobinuria can be suspected by a positive urine dipstick test for blood and minimal or no microhematuria. Due to its more rapid hepatic metabolism, myoglobin lacks sensitivity in detecting rhabdomyolysis. Therefore, serum and/or urine myoglobin measurement is not recommended to establish diagnosis. Blood urea nitrogen and creatinine help monitor the severity of AKI.
- Potassium, calcium, phosphorus, and uric levels are released from damaged muscle, and levels should be monitored.
- Calcium: Hypocalcemia from influx and deposition of calcium phosphate in damaged muscle tissue. Hypercalcemia may follow

TABLE 1 Causes of Rhabdomyolysis

Muscle injury/ischemia	Trauma, pressure necrosis, electric shock, burns, acute vascular disease
Myofiber exhaustion	Seizures, excessive exercise, heat exhaustion
Toxins	Alcohol, cocaine, heroin, amphetamines, ecstasy, phencyclidine, snakebite
Drugs	Statins, fibrates, zidovudine, neuroleptic malignant syndrome, azathioprine, theophylline, lithium, diuretics, colchicine
Electrolyte disorders	Hypophosphatemia, hypokalemia, excess water shifts (hyperosmolality)
Infections	Viral (influenza, HIV, coxsackievirus, Epstein-Barr virus), bacterial *(Legionella, Francisella, Streptococcus pneumoniae, Salmonella, Staphylococcus aureus)*
Familial	McArdle disease, carnitine palmitoyl transferase deficiency, malignant hyperthermia
Other	Hypothyroidism, polymyositis, dermatomyositis

From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

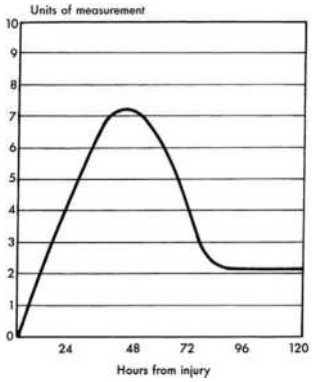

FIG. 1 Typical creatine kinase elimination curve.

resolution of rhabdomyolysis from subsequent release of muscle-sequestered calcium back into the circulation and increased gastrointestinal calcium absorption from enhanced vitamin D production.
- Anion gap metabolic acidosis may occur from release of organic acids and phosphates from damaged muscle.
- Urinalysis: Myoglobin is detected as blood on dipstick, but erythrocytes are absent on microscopy. Presence of pigmented tubular casts establishes acute tubular necrosis.
- Unlike most other causes of acute tubular necrosis, rhabdomyolysis may result in a fractional excretion of sodium (FENa) of <1% due to renal vasoconstriction.
- Box 1 summarizes laboratory abnormalities observed with rhabdomyolysis.

BOX 1 Laboratory Abnormalities Observed with Rhabdomyolysis

Potassium
Elevated
Risk for acute kidney injury

Bicarbonate
Decreased (20 mEq/L)
Metabolic acidosis

Uric Acid
Elevated (>7 mg/dl)
Marker of acute renal failure

Sodium
Usually normal
Can decrease with mannitol therapy
Use serum osmolality values as a guide

Phosphate
Elevated
Risk for precipitation of calcium phosphate
May need phosphate binders if phosphate >7 mg/dl

Creatine Kinase
Elevated
Associated with creatine kinase level of 15 to 75,000

Blood Urea Nitrogen
Elevated (>20 mg/dl)

Creatinine
Elevated

Calcium
Initially low
Rebound phase may demonstrate hypercalcemia

Liver Function Tests
Occasionally elevated
Serum aspartate transaminase, lactate dehydrogenase, aldolase, muscle enzyme levels elevated

Troponin
Normal
Suspect myocardial damage as a cause (or effect) if elevated
7% false-positive rate for troponin I

Anion Gap
Sometimes elevated
May predict acute kidney injury

Prothrombin Time, Partial Thromboplastin Time, D-Dimer
Disseminated intravascular coagulation in up to 30% of severe cases
Associated with greater mortality

From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

Rx TREATMENT

ACUTE GENERAL Rx

- Identify precipitating factor(s) and discontinuation of drugs or toxins that might be a contributing factor.
- Early, aggressive, high-volume IV fluid replacement with normal saline. Extracellular fluid volume loading and diuresis reduce the risk for renal damage by elimination of urate and phosphate that can precipitate in the kidneys. Fig. 2 describes a treatment algorithm for rhabdomyolysis.
- Fasciotomy is indicated in compartment syndrome for preservation of muscle and nerve function.
- Initiate volume repletion with normal saline at a rate of 200 to 1000 ml/hour depending on the clinical circumstances and severity of muscle damage. Titrate to maintain a urine output of at least 200 ml/hr. Consider treatment with mannitol (up to 200 g/day with cumulative dose up to 800 g) to GFR, diuresis, and scavenge free radicals. Typically, a 20% mannitol infusion at a dose of 0.5 g/kg is given over a 15-min period followed by an infusion at 0.1 g/kg/hour. Discontinue mannitol and volume resuscitation if diuresis (>20 ml/hr) is not established. Maintain volume repletion until myoglobinuria stops (negative urine dipstick blood test) or plasma CK levels decrease to <5000 U/L.
- Correct hypocalcemia if symptomatic or hyperkalemia is severe enough to produce electrocardiographic changes.
- Treatment of all electrolyte imbalances.
- Urine alkalinization: Maintain urine pH at 6 to 7 pH units and serum pH at ~7.50. This recommendation is controversial but appears helpful in research models when administered early in the course of rhabdomyolysis. Urine alkalization may prevent renal tubular myoglobin precipitation and reduce lipid peroxidation, reactive oxygen species formation, and myoglobin-induced vasoconstriction. However, early volume resuscitation and expansion is the most important treatment.
- Initiation of renal replacement therapy is guided by the severity of renal injury and electrolyte imbalances. The use of continuous renal replacement therapy or high-flux membranes to enhance myoglobin clearance has not been validated.

DISPOSITION

Early diagnosis and management are required to avoid AKI that occurs in 30% of cases. Rhabdomyolysis accounts for 7% to 10% of all cases of AKI in the U.S.

REFERRAL

Renal consultation and surgical consultation if compartment syndrome develops

PEARLS & CONSIDERATIONS

COMMENTS

- Statin-induced rhabdomyolysis occurs 12 times more frequently when statins are combined with fibrates than when used alone.
- Short-term, high-dose glucocorticoid steroid administration (500-1000 mg methylprednisolone) has been used for treatment of alcohol-induced rhabdomyolysis, refractory to volume repletion. This treatment may be efficacious in cases of severe rhabdomyolysis by retarding secondary leukocyte inflammatory muscle injury.

BASIC INFORMATION

DEFINITION

Rheumatic fever is a multisystem inflammatory disease that occurs in the genetically susceptible host 2 to 4 wk after a pharyngeal infection with group A streptococci.

SYNONYMS

ARF
Acute rheumatic fever
Rheumatic carditis

ICD-10CM CODES

I00	Rheumatic fever without heart involvement
I01	Rheumatic fever with heart involvement
I01.0	Acute rheumatic pericarditis
I01.1	Acute rheumatic endocarditis
I01.2	Acute rheumatic myocarditis
I01.8	Other acute rheumatic heart disease
I01.9	Acute rheumatic heart disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Has declined in the last 4 to 6 decades

- 0.1% to 3% in patients with untreated streptococcal pharyngitis
- Higher incidence of streptococcal pharyngitis with:
  1. Crowding
  2. Poverty
  3. Young age

INCIDENCE (WORLD): ARF remains one of the most important causes of cardiovascular morbidity and mortality among socially and economically disadvantaged people around the world.

PREDOMINANT AGE (IN U.S.):

- Age 5 to 15 yr for first attack, rare before the age of 3
- Possible relapses later

PEAK INCIDENCE (IN U.S.): School-age children

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute streptococcal pharyngitis, which may be subclinical and not reported by the patient.
- After latent period of 2 to 4 wk (average, 19 days), acute rheumatic attack.
- Patient is febrile, with a migratory polyarthritis of knees, ankles, wrists, elbows; typically severe for 1 wk, remits by 3 to 4 wk.
- Carditis:
  1. New heart murmur:
     a. Mitral regurgitation
     b. Aortic insufficiency
     c. Diastolic mitral murmur
  2. Cardiomegaly
  3. CHF
  4. Pericardial friction rub or effusion
- Rarely, pancarditis is severe and fatal.
- Subcutaneous nodules (Fig. E1) can be palpated over extensor tendon surfaces or bony prominences, such as the skull.
- Chorea (Sydenham chorea) is characterized by rapid involuntary movements affecting all muscles:
  1. Muscular weakness
  2. Emotional lability
  3. Rarely seen after adolescence and almost never in adult males
- Erythema marginatum (Fig. E2):
  1. Evanescent, pink, well-demarcated spreading to trunk and proximal extremities
  2. Not specific
- Arthralgias (joint pain without swelling).
- Abdominal pain.

ETIOLOGY

- Fig. E3 illustrates the pathophysiology of rheumatic fever. • Both initial attacks and recurrences can be completely prevented by prompt treatment of streptococcal pharyngitis with penicillin.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rheumatoid arthritis
- Juvenile rheumatoid arthritis (Still disease)
- Bacterial endocarditis
- Systemic lupus
- Viral infections
- Poststreptococcal reactive arthritis: Severe arthritis but no carditis

WORKUP

- "Jones Criteria for Guidance in the Diagnosis of Rheumatic Fever" updated in 2015 to take into consideration low-risk populations vs. moderate- and high-risk populations
- Low-risk populations: ARF incidence less than or equal to 1 per 100,000 school-aged children, or all-age rheumatic heart disease prevalence of less than or equal to 1 per 1000 population per yr
- Diagnosis, initial ARF: Two major manifestations or one major plus two minor manifestations with evidence of preceding group A *Streptococcus* (GAS) infection
- Diagnosis, recurrent ARF: Two major or one major and two minor or three minor with evidence of preceding GAS infection
- Major criteria, low-risk populations and percentage of patients with each:
  1. Carditis: Clinical and or subclinical as determined by echocardiographic valvulitis: 50% to 70%
  2. Arthritis: Polyarthritis only: 35% to 66%
  3. CNS involvement (e.g., chorea): 10% to 30%
  4. Erythema marginatum: <6% (pink, nonpruritic rash of trunk and possibly limbs)
  5. Subcutaneous nodules: 0% to 10% (firm, painless a few millimeters to 2 cm in size)
- Minor criteria, low-risk populations:
  1. Fever: Greater than or equal to 38.5° C (101.3° F)
  2. Polyarthralgia
  3. Erythrocyte sedimentation rate (ESR) >60 mm in first hour and/or C-reactive protein greater than or equal to 3.0 mg/dl
  4. Prolonged PR interval, after accounting for age variability (unless carditis is a major criterion)
- Major criteria, moderate- and high-risk populations:
  1. Carditis, clinical and/or subclinical
  2. Arthritis:
     a. Monoarthritis or polyarthritis
     b. Polyarthralgia
  3. Chorea
  4. Erythema marginatum
  5. Subcutaneous nodules
- Minor criteria:
  1. Monoarthralgia
  2. Fever greater than or equal to 38.5° C (101.3° F)
  3. ESR >30 mm/hr and/or C-reactive protein >3.0 mg/dl
  4. Prolonged PR interval, after accounting for age variability (unless carditis is a major criterion). For moderate- to high-risk patients (ARF> 2 per 100,00 school-aged children per yr or all-age rheumatic heart disease prevalence >1 per 1000 population),

FIG. E1 Subcutaneous nodules of rheumatic fever over the bony prominences of the elbow. (From Beerman LB et al: Cardiology. In Zitelli BJ et al [eds]: *Atlas of pediatric physical diagnosis,* ed 6, Philadelphia, 2012, Saunders.)

Jones criteria may underdiagnose cases, so criteria modified as follows:

a. Criterion of arthritis includes monoarthritis or polyarthralgia in addition to polyarthritis.
b. Minor criteria of joint involvement is monoarthralgia vs. polyarthralgia.
c. A lower cutoff for fever is used: ≥100.4° F (38° C).
d. A lower cutoff for sed rate is used: ≥30 mm/hr instead of ≥60 mm/hr. CRP cutoff is unchanged.

LABORATORY TESTS

- Throat cultures are usually negative at presentation of clinical manifestations of rheumatic fever.
- Streptococcal antibody tests are more useful in establishing the diagnosis.
  1. Peak at the beginning of the attack.
  2. Can document a recent streptococcal infection.
- ASO (antistreptolysin O) titers peak:
  1. 4 to 5 wk after the actual streptococcal throat infection
  2. Which coincides during the second or third wk of rheumatic fever illness
- Anti-DNase B (Streptozyme) can be detected for 6 to 9 mo following infection and can be tested if ASO titer negative.
- Other antistreptococcal antibody tests include streptokinase and antihyaluronidase.
- High-titer streptococcal antibodies:
  1. Are supportive of diagnosis, but not proof
  2. Should be interpreted in the context of clinical criteria

IMAGING STUDIES

- Chest x-ray to assess heart size.
- Echocardiogram:
  1. Echocardiography with Doppler should be performed in all cases of confirmed or suspected ARF to evaluate evidence of mitral or aortic valve regurgitation. Specific criteria exist for Doppler findings for the pathological mitral regurgitation and pathological aortic regurgitation of ARF.
  2. To rule out pericardial effusion.

FIG E2 Erythema marginatum in acute rheumatic fever. The pen mark shows the location of the rash approximately 60 min previously. (From Cohen J, Powderly WG: *Infectious diseases,* ed 2, St Louis, 2004, Mosby.)

Rx TREATMENT

ACUTE GENERAL Rx

- Course of penicillin to eradicate throat carriage of group A streptococci
- Arthralgia or arthritis without carditis: Aspirin 90 to 100 mg/kg/day for 2 wk, followed by 60 to 70 mg/kg/day for the subsequent 4 to 6 wk if needed

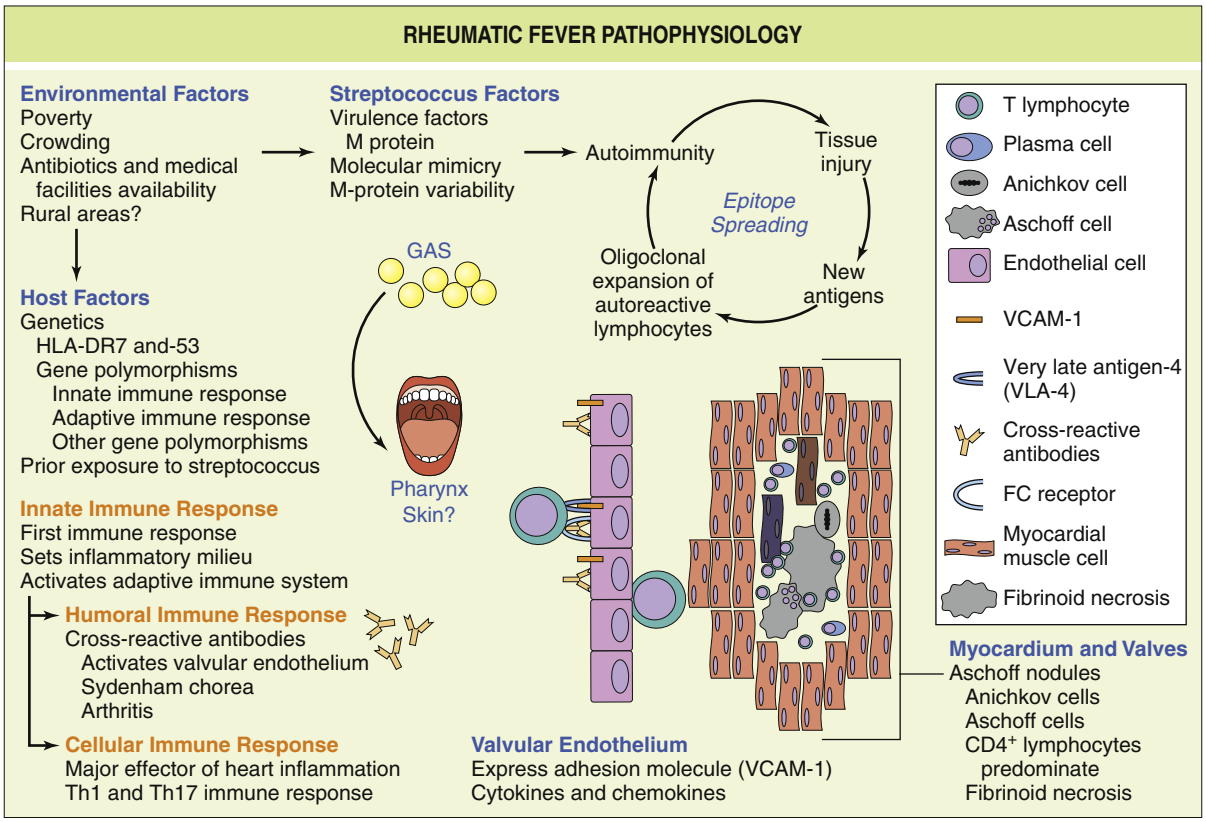

FIG. E3 Rheumatic fever pathophysiology. *GAS,* Group A β-hemolytic *Streptococcus*; *VCAM-1,* vascular adhesion molecule-1. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

- Carditis and heart failure:
  1. Prednisone 40 to 60 mg/day
  2. IV corticosteroids, such as methylprednisolone, 10 to 40 mg/day for severe carditis

CHRONIC Rx

Secondary prevention (prevention of recurrences):

- Monthly treatment with benzathine penicillin 1.2 million U IM or penicillin V: 250 mg orally bid
- Erythromycin in patients with penicillin allergy: 250 mg bid or sulfadiazine orally at 0.5 g once a day for patients <27 kg and 1.0 g daily for patients >27 kg

Duration of prophylaxis (American Heart Association recommendations):

- Rheumatic fever without carditis: 5 yr or until 21 yr of age, whichever is longer
- Rheumatic fever with carditis but without residual heart disease (no clinical or echocardiographic evidence of persistent valvular disease): 10 yr or until 21 yr of age, whichever is longer
- Rheumatic fever with carditis and residual heart disease (clinical or echocardiographic evidence of persistent valvular disease): 10 yr or until 40 yr of age, whichever is longer, sometimes lifelong prophylaxis

DISPOSITION

- Damage of heart valves because of fibrosis:
  1. Late sequela of recurrent attacks
  2. Frequent cause of valvular heart disease in developing countries
- May progress to heart failure

REFERRAL

To cardiologist for management of severe carditis

BASIC INFORMATION

DEFINITION

Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammatory polyarthritis which affects peripheral joints, especially the small joints of the hands and feet. It is a chronic, progressive disease in which untreated inflammation may lead to cartilage and bone erosions and joint destruction resulting in functional impairment.

SYNONYM

RA

ICD-10CM CODES

M06.9	Rheumatoid arthritis, unspecified
M05.10	Rheumatoid lung disease with rheumatoid arthritis of unspecified site
M05.20	Rheumatoid vasculitis with rheumatoid arthritis of unspecified site
M05.30	Rheumatoid heart disease with rheumatoid arthritis of unspecified site
M05.39	Rheumatoid heart disease with rheumatoid arthritis of multiple sites
M05.40	Rheumatoid myopathy with rheumatoid arthritis of unspecified site
M05.49	Rheumatoid myopathy with rheumatoid arthritis of multiple sites
M05.50	Rheumatoid polyneuropathy with rheumatoid arthritis of unspecified site
M05.59	Rheumatoid polyneuropathy with rheumatoid arthritis of multiple sites
M05.60	Rheumatoid arthritis of unspecified site with involvement of other organs and systems
M05.69	Rheumatoid arthritis of multiple sites with involvement of other organs and systems
M05.70	Rheumatoid arthritis with rheumatoid factor of unspecified site without organ or systems involvement
M05.79	Rheumatoid arthritis with rheumatoid factor of multiple sites without organ or systems involvement
M05.80	Other rheumatoid arthritis with rheumatoid factor of unspecified site

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Annual incidence in northern Europe and the U.S. 0.15 to 0.60 per 1000

TYPICAL AGE AT DIAGNOSIS: Usually between age 30 and 60. Steadily increases with age until the mid-70s

PREVALENCE: 0.5% to 1.0% of the worldwide population, with different rates in different ethnic groups

PREDOMINANT SEX: Females > males (2 to 3:1)

RISK FACTORS:

- Female gender, age, tobacco use, silica exposure, and obesity, family history. Smoking has an additive detrimental effect in RA patients (two-fold excess mortality risk).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Initial presentation:

- Pain, swelling, warmth in one or more peripheral joints, frequently with symmetric small joint involvement, often associated with >1 hour of morning stiffness and constitutional symptoms such as fatigue, malaise, low-grade fevers, and weight loss occurring over a period of weeks to months. A subset of patients can also present with acute-onset polyarthritis instead of insidious symptoms.
- Most common joints involved include metacarpophalangeal (MCP) joints, proximal interphalangeal (PIP) joints (Fig. E1), and metatarsophalangeal (MTP) joints (Fig. E2), as well as wrists.
- Other affected joints involved include elbows, shoulders, hips, knees, and ankles.
- Distal interphalangeal (DIP) joints are spared.
- Sacroiliac and vertebral joints are spared, except for the C1 and C2 articulations.

Chronic longstanding disease:

- "Swan-neck" (DIP flexion and PIP hyperextension) (Fig. E3), "boutonniere" (DIP hyperextension and PIP flexion), and "Z-thumb" (MCP flexion and IP hyperextension) deformities (Fig. 4), ulnar deviation and subluxation of the MCP joints as well as radial deviation of the wrists.
- C1-C2 (atlantoaxial) inflammation can lead to odontoid erosion and transverse ligament laxity/rupture, resulting in atlantoaxial subluxation and cord compression.
- Joint damage of wrists, elbows, shoulders, hips, and knees can lead to severe secondary osteoarthritis, necessitating joint surgery and/or replacement.

Extraarticular manifestations:

- Secondary Sjögren syndrome (~35%): Immune-mediated inflammation of lacrimal and salivary glands, resulting in dry mouth (xerostomia) and eyes (keratoconjunctivitis sicca).
- Rheumatoid nodules (25%): Nontender, firm nodules on extensor surfaces and pressure points, usually in rheumatoid factor positive (RF+) disease. Histopathology demonstrates palisading histiocytes surrounding a central area of fibrinoid necrosis.
- Felty syndrome: RA with splenomegaly and leukopenia. Most patients are positive for HLA-DR4 and RF.

Pulmonary disease:

- Pleural disease (exudative effusions, pleuritis)
- Interstitial lung disease (up to 10% clinically significant)
- Bronchiolitis obliterans
- Cryptogenic organizing pneumonia
- Pulmonary nodules: A combination of RA and pneumoconiosis is called Caplan syndrome

Neuromuscular:

- Entrapment neuropathy (carpal tunnel, tarsal tunnel, cubital tunnel most commonly involved)
- Mononeuritis multiplex
- Peripheral neuropathy
- Cervical myelopathy and cord compression in atlantoaxial subluxation
- Pachymeningitis (rare)

Vasculitis.

Cardiac disease:

- Pericarditis (most common)
- Myocarditis
- Valvular nodules
- There is an increased risk of cardiovascular disease compared to the general population, probably due to accelerated atherosclerosis from systemic inflammation

Ocular disease:

- Keratoconjunctivitis sicca (dry eye, without dry mouth) (10%)
- Episcleritis, scleritis, scleral thinning, scleromalacia perforans, ulcerative keratitis

Amyloidosis: Occurs in longstanding, poorly controlled RA. Usually presents as nephrotic syndrome. Can affect heart, kidney, liver, spleen, intestines, and skin.

Osteoporosis

ETIOLOGY

The exact cause of RA remains unknown despite extensive research. It is likely that a combina-

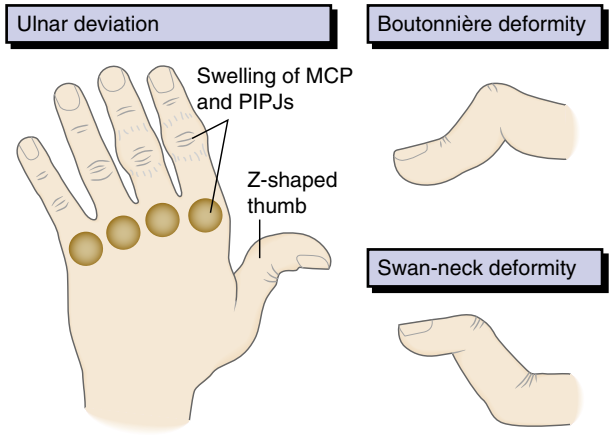

FIG. 4 Characteristic hand deformities in rheumatoid arthritis. *MCP,* Metacarpophalanges; *PIPJs,* proximal interphalangeal joints. (From Ballinger A: *Kumar & Clark's essentials of clinical medicine,* ed 6, Edinburgh, 2012, Saunders.)

tion of genetic, hormonal, and environmental factors lead to aberrant immune activation and inflammatory response in the joint. A common genetic background plays a role in susceptibility to disease, as twins and first-degree relatives of RA patients are at increased risk of developing the disease compared to the general population. Patients with HLA-DR4, DR1, and DR14 alleles have increased susceptibility to RA; in particular, one amino acid sequence in the DR β chain, known as the shared epitope, is overrepresented in these patients. Other identified genetic associations include polymorphisms in *PTPN22, PADI4*, *CTLA4*, *TRAF1-C5*, *STAT4*, *TNFAIP3*. Epigenetic factors are also likely to be involved. Multiple environmental factors have also been implicated as possible etiologic factors, including cigarette smoking, silica exposure, and low socioeconomic class. Infectious agents such as *P. gingivalis*, Epstein-Barr virus, and parvovirus B19 have also been reported as possible triggers.

Stages of disease development presumably include:

- Initiation of the innate immune response through toll-like receptor (TLR) activation by a stimulating signal.
- Perpetuation of inflammatory response through activation of the adaptive immune system. There is migration of inflammatory cells (autoreactive B and T cells, monocytes) into the joint space, activation of macrophage-like and fibroblast-like synoviocytes, and development of a "synovial pannus," a thickened synovial membrane.
- The pannus releases pro-inflammatory cytokines (TNF-α, IL-1, IL-6, IL-15, IL-17, IL-18) as well as proteases, which erode cartilage and bone. Bone erosions are caused mainly by osteoclasts, which express the receptor activator of NF-κB (RANK). TNF-α, IL-1, IL-6, and IL-17 promote the expression of RANK ligand (RANKL) on T cells and fibroblast-like synoviocytes, thus creating a positive feedback loop. IL-6 and TNF-α act synergistically to increase vascular endothelial growth factor levels, which in turn stimulate angiogenesis, thereby maintaining pannus formation. B-cell differentiation is also promoted by IL-6, leading to the production of autoantibodies.
- Many of the new "biologic" disease-modifying antirheumatic drugs (DMARDs) are engineered to target these cytokines (see "Treatment" section).

Dx DIAGNOSIS

The American College of Rheumatology (ACR) and the European League against Rheumatism (EULAR) developed new classification criteria for RA in 2010. These are based on a point system where patients with score ≥6/10 are considered to have "definite RA." Four variables constitute the new criteria:

- The number and size of involved joints (0 to 5 points, with higher scores for a larger number of small joints affected).
- Levels of rheumatoid factor (RF) and anti-cyclic citrullinated peptide (CCP) antibody (0 to 3 points, with a higher score for a high-titer positive RF or anti-CCP).
- Elevated erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) (1 point).
- Symptom duration ≥6 wk (1 point).

TABLE 1 Factors Useful for Differentiating Early Rheumatoid Arthritis from Osteoarthritis

	Rheumatoid Arthritis	Osteoarthritis
Age at onset	Childhood and adults, peak incidence in 50s	Increases with age
Predisposing factors	Susceptibility epitopes (HLA-DR4, HLA-DR1, HLA-DR14)	Trauma
	Polymorphisms, epigenetic factors, infectious agents	Congenital abnormalities (e.g., shallow acetabulum)
	Smoking, silica exposure	
Early symptoms	Morning stiffness, pain, swelling	Pain increases through the day and with use
Joints involved	Wrists, MCP, PIP, and MTP joints; DIP joints are almost never involved.	DIP joints (Heberden nodes), PIP joints (Bouchard nodes), carpometacarpal joints, weight-bearing joints (hips, knees)
Physical findings	Soft tissue swelling, warmth	Bony osteophytes, minimal soft tissue swelling early on, crepitus
Radiologic findings	Periarticular osteopenia, marginal erosions	Subchondral sclerosis, osteophytes
Laboratory findings	Increased CRP, RF, and anti-CCP antibody, anemia, thrombocytosis	Normal

anti-CCP, Anticitrullinated protein; *CRP-RF,* C-reactive protein-rheumatoid factor; *DIP,* distal interphalangeal joint; *MCP,* metacarpophalangeal joint; *MTP,* metatarsophalangeal joint; *PIP,* proximal interphalangeal joint.

DIFFERENTIAL DIAGNOSIS

- Infectious causes: Parvovirus B19, hepatitis B, hepatitis C, poststreptococcal reactive arthritis, acute rheumatic fever
- Connective tissue diseases: Systemic lupus erythematosus, scleroderma, mixed connective tissue disease, Sjögren syndrome
- Seronegative spondyloarthropathies
- Calcium pyrophosphate deposition (CPPD or "pseudo-RA")
- Polyarticular gout
- Polymyalgia rheumatica
- Remitting seronegative symmetric synovitis with pitting edema (RS3PE) can resemble seronegative RA in elderly patients
- Hemochromatosis
- Paraneoplastic syndromes
- Osteoarthritis, a degenerative arthritis that lacks prolonged morning stiffness and that usually lacks synovitis, should not be confused with RA (see Table 1)

LABORATORY TESTS

- RF (sensitivity ~60%; specificity ~80%). False positives are seen with hepatitis C, subacute bacterial endocarditis, primary biliary cirrhosis, sarcoidosis, malignancy, Sjögren syndrome, SLE, and increasing age.
- Anti-CCP antibodies. Sensitivity is similar to RF, but it is more specific for RA than RF (up to 95% to 98%).
- The presence of either RF or anti-CCP ("seropositive RA") is associated with more severe disease, more extraarticular manifestations, and worse prognosis.
- Elevated ESR and/or CRP. Will decline with treatment; thus can be used to monitor disease activity along with physical examination and clinical presentation.
- CBC with differential. Possible anemia of chronic disease (through production of the iron-regulating hormone, hepcidin) and thrombocytosis.
- Hypoalbuminemia and hypergammaglobulinemia.
- ANA is present is 20% to 30% of patients. However, complement will usually be normal or increased, in contrast to patients with systemic lupus erythematosus. Many patients will have secondary Sjögren syndrome (positive ANA with negative SSA and SSB).
- Inflammatory synovial fluid with >2000 PMNs. Of note, patients with RA have an increased risk of developing septic arthritis. Hence, synovial fluid with white blood cells >50,000 cells/mm^3 is concerning for an infectious process and must always be ruled out.

IMAGING STUDIES

Plain radiography (Table E2):

- Early changes include soft tissue swelling, symmetrical joint space narrowing, and periarticular osteopenia.
- Later changes include periarticular erosions and deformities. This reflects cartilage and bone destruction secondary to pannus formation (Fig. E5).
- Radiographs of hands and feet should be obtained at disease onset and repeated to monitor disease progression and to ensure that adequate treatment is achieved.

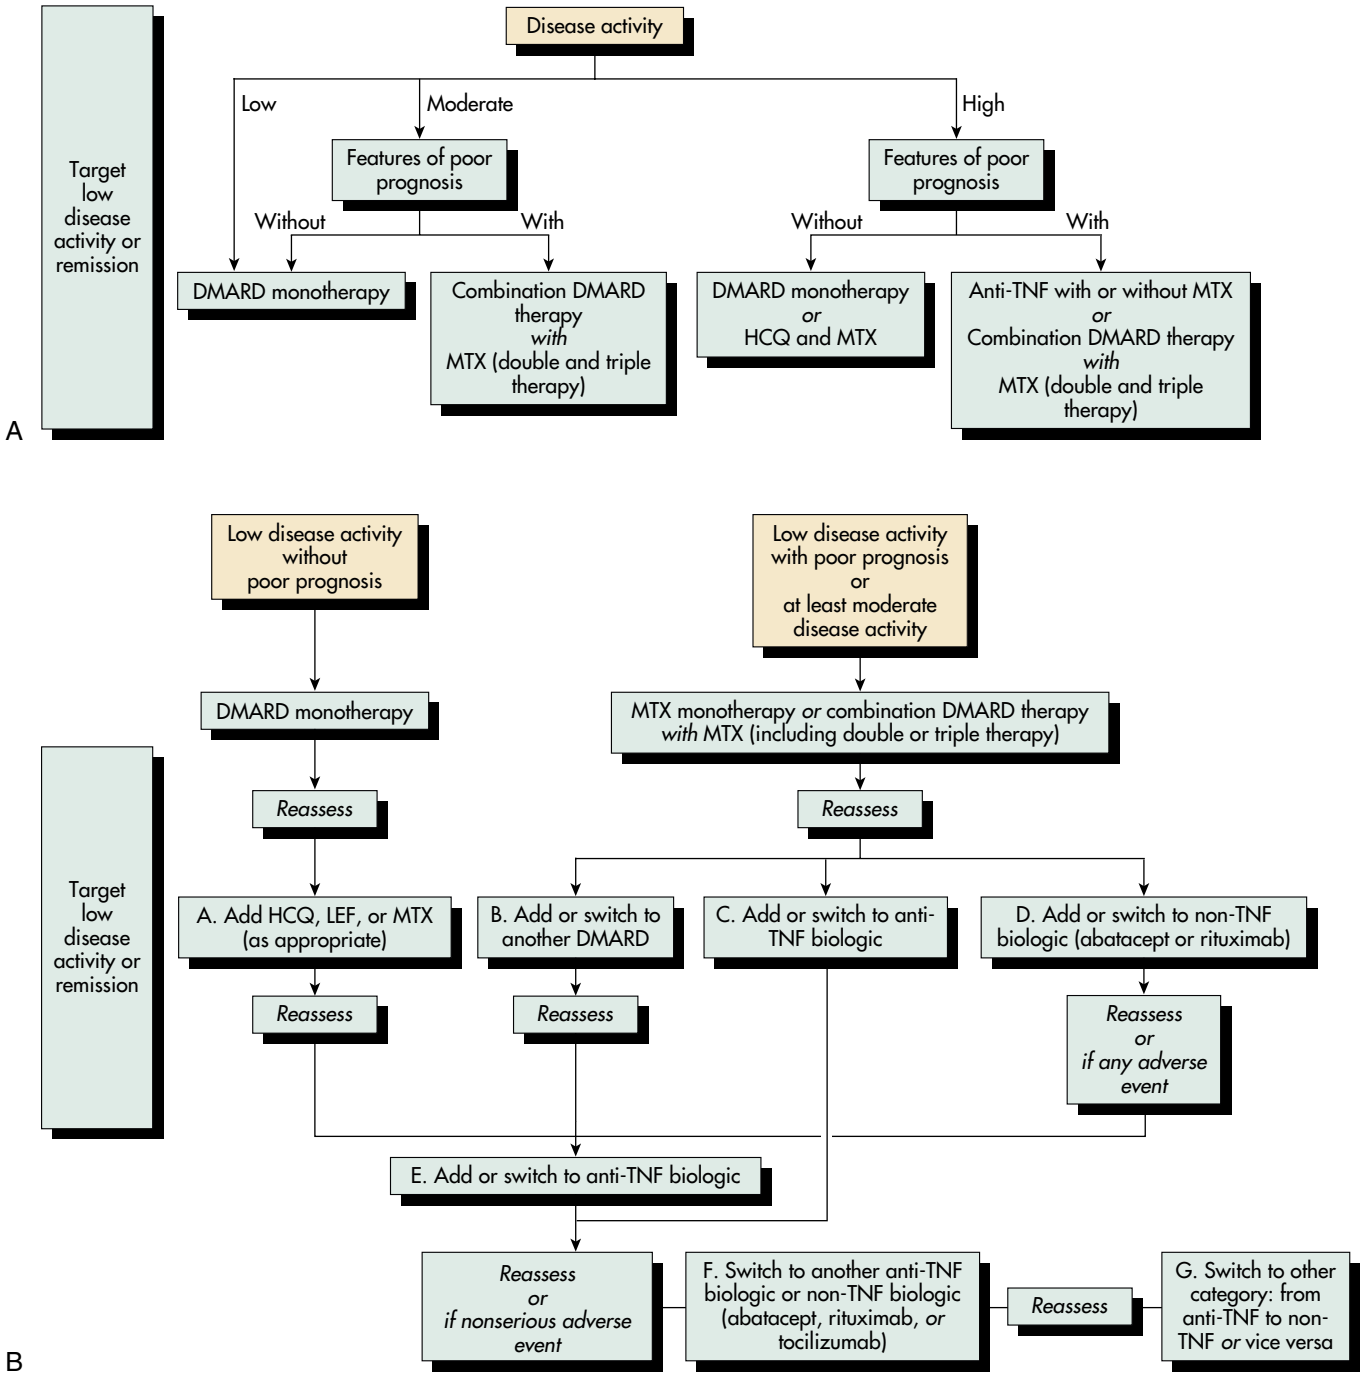

FIG. 6 American College of Rheumatology recommendations for treatment of rheumatoid arthritis. **A,** Early disease. **B,** Established disease. *DMARD,* Disease-modifying antirheumatic drug; *HCQ,* hydroxychloroquine; *LEF,* leflunomide; *MTX,* methotrexate; *TNF,* tumor necrosis factor. (From Firestein GS et al [eds]: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

MRI and musculoskeletal US:

- More sensitive for detecting erosive disease and joint effusions/synovitis

Rx TREATMENT

- Early identification and treatment of RA with DMARDs is crucial. More than half of patients have radiographic joint damage within 2 yr of disease onset, but early aggressive treatment with DMARDs and/or biologic agents is associated with decreased progression of synovitis and bone erosions, and with decreased disability. Fig. 6 describes the American College of Rheumatology recommendations for treatment of rheumatoid arthritis. Goal of therapy is to "treat to a target" of low disease activity or remission.
- There are several tools to measure disease activity and define remission in rheumatoid arthritis, including (but not limited to) the following: Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), Disease Activity Score (DAS) 28, Routine Assessment of Patient Index Data 3 (RAPID3), Stanford Health Assessment Questionnaire (HAQ), and Patient Activity Scale (PAS).

ACUTE GENERAL Rx

- NSAIDs: Can be used initially to relieve pain and mild inflammation, or used later in the disease course for additional control of mild pain. NSAIDs are not disease modifying.
- Corticosteroids: Oral or intraarticular, frequently used initially to reduce inflammation rapidly until oral DMARD treatments take

effect. They may also be used during acute flares or in low doses for additional control of inflammation. The use of corticosteroids at the lowest dose possible and shortest duration is recommended. Corticosteroids have many side effects, including but not limited to weight gain, increased risk of diabetes, osteoporosis, cataract formation, peptic ulcer disease (especially when used in combination with NSAIDs), and avascular necrosis.

CHRONIC Rx

- DMARDs: Can be classified into "nonbiologic" and "biologic" treatments.
  1. Nonbiologic DMARDs: Most commonly used agents are methotrexate (MTX), hydroxychloroquine (HCQ), sulfasalazine (SSZ), and leflunomide (LEF). Most of these are associated with potential toxicity and require close monitoring. They are also slow-acting drugs that generally require >8 wk to start taking effect.
  2. MTX is the most commonly used DMARD worldwide for the treatment of RA. It is effective as monotherapy in about 30% of patients with RA.
  3. "Triple therapy"—MTX, HCQ, and SSZ—has been shown to be superior to MTX alone.
- Biologic DMARDs: Newer biologically engineered therapies, which target cytokines and cells involved in the RA inflammatory response. Major side effects include an increased risk of infections, most notably reactivation of tuberculosis with anti-TNF agents. A negative PPD or interferon γ-release assay is a prerequisite to initiate therapy. Biologic DMARDs are most effective when used in combination with a nonbiologic DMARD, usually MTX.
- The five approved tumor necrosis factor α inhibitors (TNFI) include infliximab, etanercept, adalimumab, certolizumab pegol, and golimumab.
- Abatacept (CTLA-4Ig) is a recombinant protein that prevents costimulatory binding of antigen presenting cell to T cell, preventing T-cell activation.
- Tocilizumab (anti–IL-6) is a monoclonal antibody against the IL-6 receptor.
- Sarilumab is another IL-6 inhibitor monoclonal antibody, approved by the FDA in 2017 for treatment of RA, and can be used as monotherapy or in combination with MTX or other conventional DMARDs.
- Tofacitinib (JAK1/2/3 inhibitor) inhibits the JAK-STAT intracellular signaling pathway, thus preventing the production of inflammatory mediators. The first oral biologic DMARD, it can be used as monotherapy or in combination with MTX. Baricitinib, an oral, once-daily Janus kinase (JAK1 and JAK2) inhibitor, has been approved by the FDA in May 2018 for treatment of moderate to severe RA in patients who did not respond adequately to one or more TNFIs. A dose of 2 mg was approved, with concerns that higher doses had increased adverse events. Upadacitinib (JAK1 > JAK2/3 inhibitor) was approved in 2019 at 15 mg once daily for moderate to severely active RA resistant or intolerant to MTX, or in combination with MTX with other nonbiologic DMARDs.
- Rituximab (anti-CD20) is a monoclonal antibody against the CD20 antigen on B lymphocytes.
- Biosimilars are beginning to be available. These molecules are highly similar, but not identical, to the original drugs. Legal disputes have delayed the widespread adoption of these drugs in the U.S., but they are likely to be of increasing prevalence in the future.
- Treatment recommendations in RA patient with high-risk comorbidities:
  1. TNFI should be avoided in patients with congestive heart failure, as it can worsen the condition.
  2. In patients with hepatitis B, immunosuppressive therapy can be safely prescribed along with concomitant antiviral therapy.
  3. Treatment of hepatitis C patients with RA should be done following standard guidelines in collaboration with gastroenterology/hepatology. Immunosuppressive therapy can be used safely in conjunction with antiviral therapy; avoidance of DMARDs such as MTX and LEF should be taken into consideration.
  4. In patients with a history of skin cancer, DMARDs are recommended over the use of biologics. For patients with previously treated lymphoproliferative disorders, use of rituximab should be considered first, as well as combination DMARDs and non-TNF biologics. One should avoid TNFI, as there is an increased risk of lymphoma with these agents. Recommendations for treatment of patients with previously treated solid organ malignancy are the same as for patients without the condition.

Immunization, cardiovascular disease prevention (smoking cessation, blood pressure control, cholesterol control), and osteoporosis prevention (with calcium and vitamin D supplementation and bisphosphonate therapy) should be addressed in all RA patients.

DISPOSITION

- Remissions and exacerbations are common, but condition is chronically progressive in the majority of cases.
- Joint degeneration and deformity often lead to disability. Joint replacement is indicated for patients with severe joint damage whose symptoms are poorly controlled by medical management. The ACR published guidelines in 2017 concerning the perioperative management of antirheumatic medications in patients undergoing elective total hip or total knee arthroplasty.
- Early and aggressive diagnosis and treatment are crucial in preventing or slowing joint destruction.

REFERRAL

- Early referral to rheumatologist
- Orthopedic consultation for corrective surgery

PEARLS & CONSIDERATIONS

RA sometimes develops acutely in the postpartum patient; conversely, as high as 75% of pregnant RA patients will experience remission during pregnancy.

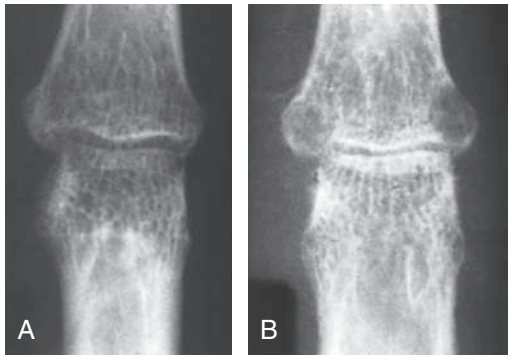

FIG. E1 Rheumatoid arthritis. (A) Initial x-ray shows early trabecular loss around the finger proximal interphalangeal joint with joint space preservation. **(B)** Subsequently there is erosive change with joint space narrowing. (From Sutton D: *Textbook of radiology and imaging,* ed 7, 1998, Churchill Livingstone. In Grant LA *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

FIG. E2 Rheumatoid arthritis with the earliest feature of erosive change seen along the radial border of this middle metacarpal head. There is localized osteopenia with a "dot-dash" pattern of deossification *(white arrow)*. Note also the symmetrical soft-tissue swelling and frank erosion of the ulna border *(black arrow)*. (From Adam A et al: *Grainger and Allison's diagnostic radiology,* ed 6, 2015, Elsevier. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

FIG. E3 Rheumatoid arthritis. Bilateral symmetrical changes with soft tissue swelling (especially over the ulnar styloids). Erosions are seen at the carpus, metacarpophalangeal joints, distal radius and ulna with joint space narrowing and bone collapse. There is a swan neck deformity of the right 5th distal interphalangeal joint. (From Sutton D: *Textbook of radiology and imaging,* ed 7, 1998, Churchill Livingstone. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

TABLE E2 Plain Radiographic Findings in Rheumatoid Arthritis and Corresponding Pathophysiological Causes

Radiological Findings	Pathological Cause
Periarticular osteoporosis	This reflects localized hyperemia and is most pronounced during the acute stages of the disease
Soft tissue swelling	This represents synovial hypertrophy, joint effusion and periarticular soft tissue edema, and is typically symmetrical
Erosions	These are marginal in location caused by the inflammatory and erosive effect of the inflamed synovium on the "bare area" of the joint (that part of the joint adjacent to the synovium which is not covered by cartilage)
Joint space narrowing	This results from cartilage loss. Early uniform cartilage loss results from interruption of the flow of synovial fluid nutrients by the pannus. Later the hypertrophied synovium causes direct destruction with undermining of the cartilage and destruction of the subchondral bone. There may be joint widening in the early stages or ankylosis in the end stages of the disease
Subchondral cysts	These result from destruction of the subchondral plate by pannus, which allows joint fluid to be forced into the subchondral bone under pressure
Joint subluxation and dislocation	These are due to damage or destruction to tendons and ligaments as a result of the inflammatory pannus. In the early stages the deformity may be reversible and therefore underestimated on plain films
Generalized regional osteoporosis	This results from pain-induced disuse and may be exacerbated by the effects of therapy (e.g., steroids)

From Adam A et al: *Grainger & Allison's diagnostic radiology,* ed 5, 2007, Churchill Livingstone. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.

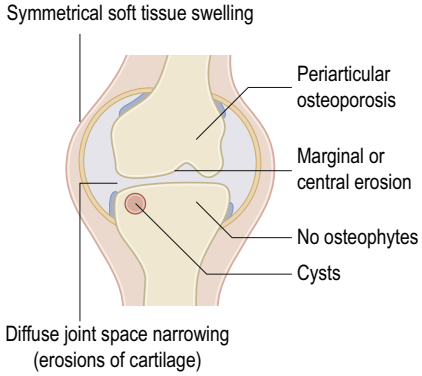

FIG. E5 Diagram showing the typical radiographic changes in rheumatoid arthritis. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

Rocky Mountain Spotted Fever PTG

BASIC INFORMATION

DEFINITION

Rocky Mountain spotted fever (RMSF) is a life-threatening, tickborne febrile illness caused by infection with *Rickettsia rickettsii*. The infection occurs when *R. rickettsii* in the salivary glands of a vector tick is transmitted into the dermis, spreading and replicating in the cytoplasm of endothelial cells and eliciting widespread vasculitis and end-organ damage.

SYNONYM

RMSF

ICD-10CM CODE

A77.0 Spotted fever due to *Rickettsia rickettsii*

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 0.18 to 0.32 cases per 100,000 person/yr. Infections have been reported throughout the U.S.

PREVALENCE: Most prevalent in the Southeast, followed by the South Central states, but seen nywhere (Fig. E1). The RMSF main territory" extends from North Carolina to Oklahoma. It has recently been reported in eastern Arizona, with common brown dog ticks *(Rhipicephalus sanguineus)* implicated as a vector of *R. rickettsii.*

PREDOMINANT SEX: Affects both genders equally

PREDOMINANT AGE: Occurs at any age, but more likely in children ages 5 to 14 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation: 3 to 12 days
- First symptoms: Fever, headache, malaise, myalgias

Common History, Signs, or Symptom	%
Tick bite	65
Fever	100
Rash	>90
Rash on palms and soles (Fig. E2)	80
Headache	90
Myalgia	75
Nausea or vomiting	60
Abdominal pain	40
Conjunctivitis	30
Edema	20
Pneumonitis	15
Any severe neurologic complication (including stupor, delirium, seizures, ataxia, papilledema, focal neurologic deficits, and coma)	30

- Rash: A petechial rash is the hallmark of RMSF:
  1. Appears during first 3 days in 50%; by day 5, 90% have it. No rash in <10%.
  2. Initial appearance: Blanching erythematous macules on wrists and ankles that then spread to trunk, palms, and soles (Fig. E3). The rash involves palms and soles in more than 30% of cases and usually spares the face.
  3. Lesions may evolve into papules and eventually become nonblanching (petechiae or palpable purpura).
- Gastrointestinal symptoms:
  1. Nausea, vomiting, and abdominal pain are common
  2. Occasionally may mimic an "acute abdomen" (e.g., appendicitis, cholecystitis)
  3. Mild hepatitis
- Cardiopulmonary involvement:
  1. Interstitial pneumonitis
  2. Myocarditis
- Renal problems:
  1. Prerenal azotemia
  2. Interstitial nephritis
  3. Glomerulonephritis
- Neurologic involvement:
  1. Encephalitis (confusion, lethargy, delirium)
  2. Ataxia
  3. Convulsion
  4. Cranial nerve palsy
  5. Speech impediment
  6. Hemiparesis or paraparesis
  7. Spasticity
- Fulminant RMSF:
  1. Early, widespread vascular necrosis leading to multisystem illness and death

ETIOLOGY & PATHOGENESIS

- Infectious agent: *R. rickettsii* (an intracellular bacterium).
- Vector: Dog tick and wood tick (vertical transmission exists in ticks, but horizontal transmission involving rodents represents an important reservoir for the agent). In the U.S., *R. rickettsii* is transmitted mainly by the American dog tick *(Dermacentor variabilis)* and the Rocky Mountain wood tick *(D. andersoni).*
- Pathogenesis: The spread of *R. rickettsii* is hematogenous with attachment to the vascular endothelium, causing a vasculitis. The manifestations of this illness are caused by increased vascular permeability.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Influenza A, enteroviral infection, typhoid fever, leptospirosis, infectious mononucleosis, viral hepatitis, sepsis, ehrlichiosis, gastroenteritis, acute abdomen, bronchitis, pneumonia, meningococcemia, disseminated gonococcal infection, secondary syphilis, bacterial endocarditis, toxic shock syndrome, scarlet fever, rheumatic fever, measles, rubella, typhus, rickettsialpox, Lyme disease, drug hypersensitivity reactions, idiopathic thrombocytopenic purpura, thrombotic thrombocytopenic purpura, Kawasaki syndrome, immune complex vasculitis, connective tissue disorders.

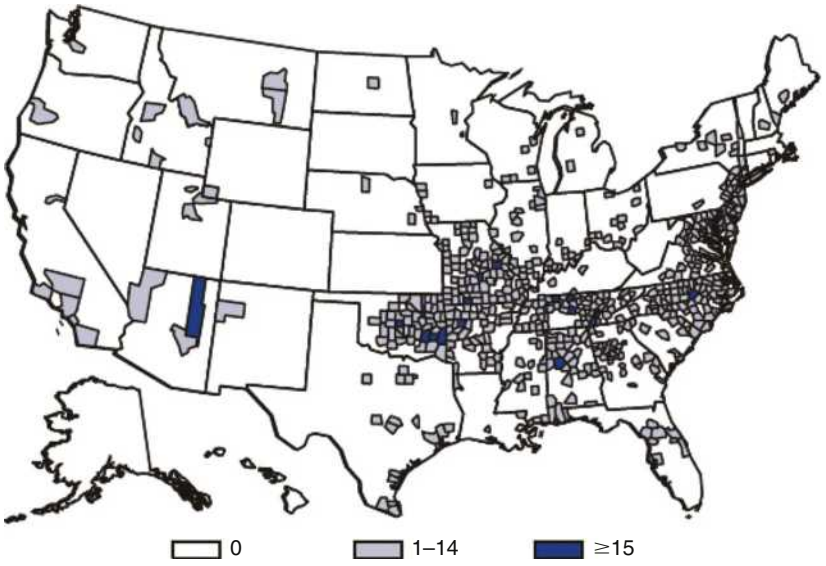

FIG. E1 Spotted fever rickettsiosis. Number of reported cases, by county, U.S., 2010. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, 2010, *MMWR Morb Mortal Wkly Rep* 59[53]:1-111, 2012.)

FIG. E2 Palmar rash associated with Rocky Mountain spotted fever. (From Walker DH, Raoult D: *Rickettsia rickettsii* and other spotted fever group rickettsiae [Rocky Mountain spotted fever and other spotted fevers]. In Mandell GL et al [eds]: *Principles and practice of infectious diseases,* ed 5, New York, 2000, Churchill Livingstone.)

FIG. E3 Late appearance of rash: Rocky Mountain spotted fever manifesting on lower extremity. (Courtesy of Theodore Woodward, MD. From Marx JA et al: *Rosen's emergency medicine: concepts and clinical practice,* 7 ed, Philadelphia, 2010, Elsevier.)

WORKUP

- Consider RMSF in any patient with an acute febrile illness with headache and myalgia, especially with an associated history of tick exposure. Absence of rash does not rule out the diagnosis.
- Rickettsial antibodies take several weeks to develop; therefore, serologic testing is of limited utility in acute illness.
- Box E1 shows the diagnostic criteria for Rocky Mountain spotted fever.

LABORATORY TESTS

- Thrombocytopenia and elevated aminotransferase are common (see the following).
- Cerebrospinal fluid analysis reveals a lymphocyte-predominant pleocytosis.

Routine Tests	%
White cell count	
<10,000/mm^3	72
>10% bands	69
Platelet count	
<150,000/mm^3	52
<99,000/mm^3	32
Serum sodium value <132 mEq/L	56

BOX E1 Diagnostic Criteria for Rocky Mountain Spotted Fever

Laboratory Criteria

- Serologic evidence of a significant change in serum antibody titer reactive with *Rickettsia rickettsii* antigens between paired serum specimens, as measured by a standardized assay conducted in a commercial, state, or reference laboratory
- Demonstration of *R. rickettsii* antigen in a clinical specimen by immunohistochemical methods
- Detection of *R. rickettsii* DNA in a clinical specimen by the polymerase chain reaction (PCR) assay
- Isolation of *R. rickettsii* from a clinical specimen in cell culture

For confirmed cases, a significant change in titer must be determined by the testing laboratory; examples of commonly used measures of significant change include, but are not limited to, a fourfold or greater change in antibody titer as determined by indirect immunofluorescent antibody (IFA) assay or an equivalent change in optical density measured by enzyme-linked immunosorbent assay (EIA or ELISA).

Case Classification (CDC Case Definition, 2004)

Confirmed: The patient has a clinically compatible illness that is laboratory confirmed.
Probable: The patient has a clinically compatible illness and serologic evidence of antibody reactive with *R. rickettsii* in a single serum sample at a titer considered indicative of current or past infection (cutoff titers are determined by individual laboratories).

CDC, Centers for Disease Control and Prevention.
From Diagnosis and management of tickborne rickettsial diseases: Rocky Mountain spotted fever, ehrlichioses, and anaplasmosis—United States. *MMWR Recomm Rep* 55(RR-4):18, 2006, and from Marx JA et al: *Rosen's emergency medicine: concepts and clinical practice,* 7 ed, Philadelphia, 2010, Elsevier.

Routine Tests	%
Aspartate aminotransferase ≥2× normal	62
Alanine aminotransferase ≥2× normal	39
Bilirubin value >1.4 mg/dl	30
Cerebrospinal Fluid	
Opening pressure ≥250 mm H_2O	14
Glucose value ≤50 mg/dl	8
Protein value ≥50 mg/dl	35
White cell count ≥5/mm^3	38
Mononuclear cell predominance	46
Polymorphonuclear cell predominance	50

- Etiologic tests:
  1. Antibody titers to *R. rickettsii* (by indirect fluorescent antibody test). The diagnosis of RMSF requires a fourfold increase 2 wk apart and thus is not helpful in the care of the patients despite a sensitivity and specificity of near 100%.
  2. The only test that can provide a timely diagnosis is the immunohistologic demonstration of *R. rickettsii* in skin biopsy specimens.

Rx TREATMENT

- Oral or IV doxycycline is first-line treatment. Administer 200 mg/day in 2 divided doses for 7 days or for 2 days after defervescence.
- Chloramphenicol, 50 mg/kg/day in 4 divided doses is an alternative treatment; chloramphenicol may be preferred during pregnancy because of the effects of doxycycline on fetal bones and teeth; therapy continued for at least 2 days after defervescence.

PROGNOSIS

- It is imperative to give antibiotic treatment empirically when RMSF is suspected.
- Fatality rate: 5% to 10% (five times greater if treatment is initiated after day 5 of illness, which is more likely in the absence of rash and during seasonal nonpeak tick activity). Long-term sequelae seen in patients who recover from severe RMSF: Paraparesis, hearing loss; peripheral neuropathy; bladder and bowel incontinence; cerebellar, vestibular, and motor dysfunction; language disorders; limb amputation; and scrotal pain after cutaneous necrosis.

RELATED CONTENT

Rocky Mountain Spotted Fever (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Rosacea is a chronic skin disorder characterized by papules and pustules affecting the face and often associated with flushing and erythema.

SYNONYM

Acne rosacea

ICD-10CM CODES

L71 Rosacea
L71.9 Rosacea unspecified
L71.1 Rhinophyma
L71.8 Other rosacea
L71.0 Perioral dermatitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Rosacea occurs in 1 in 20 Americans
- Onset often between ages 30 and 50 yr
- More common in people of Celtic origin; however, this disease may be overlooked in nonwhites because skin pigmentation results in atypical presentation
- Female:male ratio of 3:1

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Facial erythema, presence of papules, pustules, and telangiectasia (Fig. E1).
- Excessive facial warmth and redness are the predominant presenting symptoms.
- Itching is generally absent.
- Comedones are absent (unlike acne).
- Women are more likely to show symptoms on the chin and cheeks, whereas in men the nose is commonly involved.
- Ocular findings (mild dryness and irritation with blepharitis, conjunctival injection, burning, stinging, tearing, eyelid inflammation, swelling, and redness) are present in 50% of patients.

Rosacea can be classified into four major subtypes (Table E1):

1. Erythematotelangiectatic (vascular): Erythema in central part of face, telangiectasia, flushing
2. Papulopustular (inflammatory): Presence of dome-shaped erythematous papules and small pustules, in addition to facial erythema, flushing, and telangiectasia
3. Phymatosis/glandular rosacea (Fig. E2): Presence of thickened skin with prominent pores that may affect the nose (rhinophyma) (Fig. E3), chin (gnathophyma), forehead (metophyma), eyelids (blepharophyma), and ears (otophyma)
4. Ocular: Conjunctival injection, sensation of foreign body in the eye, telangiectasia and erythema of lid margins, scaling

ETIOLOGY

- The pathophysiology of rosacea is incompletely understood but believed to involve the vasculature.
- Hot drinks, alcohol, and sun exposure may accentuate the erythema by causing vasodilation of the skin.
- Flare-ups may also result from reactions to medications (e.g., simvastatin, angiotensin-converting enzyme inhibitors, vasodilators, fluorinated corticosteroids), stress, extreme heat or cold, wind, humidity, strenuous exercise, spicy drinks, menstruation.

DIAGNOSIS

The presence of at least one of the following primary features in a central distribution of the face is generally sufficient to diagnose rosacea: Papules and pustules, telengiectasia, flushing (transient erythema), nontransient erythema.

DIFFERENTIAL DIAGNOSIS

- Drug eruption
- Acne vulgaris
- Contact dermatitis
- Systemic lupus erythematosus
- Carcinoid flush
- Idiopathic facial flushing
- Seborrheic dermatitis
- Facial sarcoidosis
- Photodermatitis
- Mastocytosis
- Perioral dermatitis
- Granulomas of the skin

WORKUP

Diagnosis is based on clinical findings. Distinguishing features between acne and rosacea are the presence of telangiectasia and deep diffuse erythema and absence of comedones in rosacea.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Instruct patients to keep a diary to identify stimuli and triggers that exacerbate rosacea (e.g., spicy foods, drugs, cosmetics) and avoid identified triggers.
- Avoid alcohol, excessive sun exposure, and hot drinks of any type.
- Use of mild, nondrying soap or soap-free cleansers and nonoily moisturizers is recommended; local skin irritants should be avoided. General recommendations for skin care in patients with rosacea are summarized in Table 2.
- Sunscreens are an important component of therapy and should be applied each morning.
- Daily circular massage for several minutes of the central portion of the face is helpful in decreasing lymphedema and inflammation in this area.
- Reassure patient that rosacea is completely unrelated to poor hygiene.
- Vascular laser surgery is effective for telangiectasia.
- Surgical options are available for telangiectasia and rhinophyma and include

TABLE 2 General Recommendations for Facial Skin Care and Education in Patients With Rosacea

Facial Skin Care

- Wash with lukewarm water and use soap-free cleansers that are pH balanced.
- Cleansers are applied gently with fingertips.
- Use sunscreens with both UVA and UVB protection and an SPF ≥30.
- Sunscreens containing the inorganic filters titanium dioxide and/or zinc oxide are usually well tolerated.
- Use cosmetics and sunscreens that contain protective silicones.
- Water-soluble facial powder containing inert green pigment helps to neutralize the perception of erythema.
- Moisturizers containing humectants (e.g., glycerin) and occlusives (e.g., petrolatum) help to repair the epidermal barrier.
- Avoid astringents, toners, and abrasive exfoliators.
- Avoid cosmetics that contain alcohol, menthols, camphor, witch hazel, fragrance, peppermint, and eucalyptus oil.
- Avoid waterproof cosmetics and heavy foundations that are difficult to remove without irritating solvents or physical scrubbing.
- Avoid procedures such as glycolic peels or dermabrasion.

Patient Education

- Reassure the patient about the benign nature of the disorder and the rarity of rhinophyma, particularly in women.
- Emphasize the chronicity of the disease and the likelihood of exacerbations.
- Direct patients to information websites such as those of the National Rosacea Society (www.rosacea.org) or the American Academy of Dermatology (www.aad.org).
- Advise to avoid recognized triggers.
- Explain the importance of compliance with topical regimens.
- Educate on the importance of sun avoidance.•

SPF, Sun protective factor; *UVA,* ultraviolet A; *UVB,* ultraviolet B.

Therapy, *J Am Acad Dermatol* 51:499-512, 2004; In From Bolognia J: *Dermatology,* ed 4, 2018, Elsevier.

dermabrasion, laser ablation, heated scalpel, electrocautery, and radiofrequency electrosurgery.

GENERAL Rx

- Several classes of drugs are used in treatment of rosacea, including the metronidazole family, the tetracycline family, ivermectin cream, and azelaic acid.
- Vascular rosacea: Topical therapy with metronidazole aqueous gel (MetroGel) applied bid is effective as initial therapy for mild cases. A new 1% formulation of metronidazole (Noritate) applied daily may improve patient compliance. Clindamycin lotion (Cleocin), sulfacetamide, or erythromycin 2% solution may also be effective. Brimonidine (Mirvaso) is a selective alpha$_2$-adrenergic receptor agonist FDA-approved as a gel preparation for topical treatment of adults with persistent facial erythema of rosacea. Oxymetazoline (Rhofane) 1% cream is also an FDA-approved selecting alpha1a-adrenergic receptor agonist for topical treatment of persistent facial erythema in adults. Neither brimonidine or oxymetazoline are indicated for the treatment of inflammatory lesions of rosacea.
- Pustular and ocular rosacea: Systemic antibiotics (doxycycline 100 mg qd or tetracycline 250 mg qid until symptoms diminish, then taper off). Minocycline 50 to 100 mg qd should be used only in resistant cases because this medication is expensive. Oral metronidazole (200 mg qd to bid) for 4 to 6 wk is also effective. A 1% cream formulation of the antiparasitic drug ivermectin (Soolantra) is effective for papulopustular rosacea with minimal adverse effects. After 3 months of therapy, it will produce clearing of rosacea lesions in up to 80% of patients with moderate to severe symptoms. Its mechanism of action is unknown, but it may be due to the combination of its antiinflammatory effects and its antiparasitic effects on the Demodex mite, which may contribute to the symptoms of rosacea. Cost may be a limiting factor ($320 for one 30-g tube).
- Isotretinoin (Accutane) 0.5 to 1 mg/kg/day in two divided doses for 15 to 20 wk can be used for refractory papular and pustular rosacea; use of retinoids may, however, worsen erythema and telangiectasis.
- Erythema and flushing may respond to low-dose clonidine (0.05 mg bid).
- Treatment of phymatous rosacea: Oral tetracyclines, oral isotretinoin, ablative/pulsed dye laser therapy, electrosurgery.
- Treatment of ocular rosacea: Topical or oral tetracyclines, artificial tears, and/or lid cleansing for eyelid hygiene. Medical and surgical therapies for rosacea are summarized in Table E3.

DISPOSITION

- Rosacea is often resistant to initial treatment and recurrent. Periods of remission and relapse are common.
- The progression of rosacea is variable. Typical stages include:
  1. Facial flushing
  2. Erythema and/or edema and ocular symptoms
  3. Papules and pustules
  4. Rhinophyma

PEARLS & CONSIDERATIONS

COMMENTS

- The course of the disease is typically chronic, with remissions and relapses.
- Patients with resistant cases may have *Demodex folliculorum* mite infestation or tinea infection (diagnosis can be confirmed with potassium hydroxide examination); the role of *D. folliculorum* in rosacea is unclear. These mites can sometimes be found in large numbers in the lesions; however, their numbers do not generally decline with treatment.
- Rosacea can result in emotional and social stigmas, especially because many people associate rosacea and rhinophyma with alcohol abuse.
- Early consultation with an ophthalmologist is recommended in patients with suspected ocular involvement.

FIG. E1 Papulopustular rosacea. (Courtesy Curt Samlaska, MD. From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

TABLE E1 Differential Diagnosis of the Four Subtypes of Rosacea

Rosacea Subtype and Differential Diagnosis	Distinguishing Feature(s) from Rosacea
Erythematotelangiectatic rosacea	
Actinic damage (telangiectatic photoaging)	• Also characterized by facial telangiectasias and erythema, but the latter favors the lateral more than the central face • There tends to be less transient and nontransient erythema • Some patients have both disorders
Seborrheic dermatitis	• Erythema with greasy scale in the eyebrows, nasolabial folds, auditory meatus, retroauricular sulcus, and scalp • Involvement of eyelid creases • Patients often have both disorders
Keratosis pilaris rubra	• Onset usually during adolescence • Background erythema of the lateral cheeks with superimposed tiny follicular papules
Acute cutaneous lupus erythematosus	• Absence of inflammatory papulopustules and ocular changes • At least 75%-80% of patients have systemic signs/symptoms of SLE • Often more well-demarcated edematous plaques with sparing of the nasolabial fold
Flushing (idiopathic or secondary)	• Intermittent erythema and warmth • Flushing in patients with rosacea is usually limited to the face • Consider other common etiologies (e.g., menopause, anxiety disorder) or a tumor-related phenomenon (carcinoid syndrome, occult pheochromocytoma, mastocytosis) when additional anatomic sites are involved or there are associated symptoms such as tachycardia and sweating
Papulopustular rosacea	
Acne (vulgaris)	• Onset at a younger age • Comedones, both open and closed, and cysts • Greater involvement of the upper trunk
Steroid-induced rosacea	• Clinical overlap with periorificial dermatitis
Demodicosis (*Demodex* folliculitis)	• Patients often immunosuppressed (HIV infection, leukemia) • Involves face, especially the nose, and upper chest • Responds to topical permethrin ± oral ivermectin

Continued

TABLE E1 Differential Diagnosis of the Four Subtypes of Rosacea—cont'd

Rosacea Subtype and Differential Diagnosis	Distinguishing Feature(s) from Rosacea
Pityriasis folliculorum	• See text
Tinea incognito, candidiasis	• Both can mimic rosacea, especially if topical corticosteroids have been used • KOH examination demonstrates hyphae or budding yeasts
Papulopustular eruptions due to EGFR inhibitors	• Occurs in up to 90% of patients on these drugs • Abrupt onset • May also involve scalp, neck, and trunk
Follicular mucinosis	• Multiple papules but not pustules
Ocular rosacea	
Seborrheic dermatitis	• Involvement beyond the eyelid margin; may be accentuated in the eyelid creases
Drug-induced ocular rosacea	• Eyedrops used to treat other ocular disorders, e.g., glaucoma
Phymatous rosacea	
Lupus pernio (sarcoidosis)	• Violaceous indurated plaque of the distal nose
Discoid lupus erythematosus	• Erythema, scaling, follicular plugging, and tendency to scarring
Lupus vulgaris (cutaneous TB)	
Neoplasms	• Basal cell carcinoma, lymphoma, angiosarcoma, cutaneous metastases ("clown nose")

Occasionally, trichostasis spinulosa has associated erythema, but detection of multiple hairs within the follicular orifice by dermoscopy or microscopic examination of follicular contents establishes the diagnosis. *EGFR,* Epidermal growth factor receptor; *KOH,* potassium hydroxide; *SLE,* systemic lupus erythematosus; *TB,* tuberculosis.
From Bolognia J: *Dermatology,* ed 4, 2018, Elsevier.

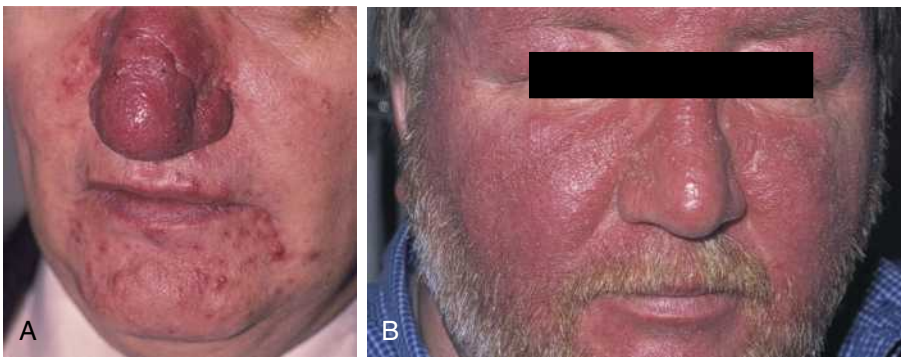

FIG. E2 Severe rosacea. A, Note the scattered papules on the face and the confluent involvement of the nose. Alcohol ingestion is not related to this appearance. **B,** Note the severe inflammation with confluent redness and significant edema. (From White GM, Cox NH [eds]: *Diseases of the skin: a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

FIG. E3 Glandular rosacea. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

TABLE E3 Medical and Surgical Therapies For Rosacea

Treatment	Comments and/or Doses
Erythematotelangiectatic	
Facial skin care recommendations (see Table 2)	Particularly useful as this subtype is prone to skin irritation and "sensitivity"
Photoprotection	UVR may potentiate dermal matrix damage
Topical agents, e.g., azelaic acid, metronidazole	May reduce erythema, but their use is often limited by their irritant effects
Topical brimonidine tartrate (0.33% gel)*,†	Selective α_2-adrenergic agonist that improves erythema
Topical oxymetazoline HCl (1% cream)*	Selective α_{1A}-adrenergic agonist that improves erythema
Laser therapy†	Use of vascular lasers (e.g., pulsed dye, potassium titanyl phosphate) as well as intense pulsed light may improve grades 2 and 3
Papulopustular	
Topical	
Metronidazole (0.75% gel or cream; 1% cream)*,† once or twice daily	Can be used as initial treatment to clear inflammatory lesions or as indefinite maintenance therapy
Ivermectin (1% cream)*,† once daily	More effective than placebo and slightly more effective than topical metronidazole in randomized controlled trials
Azeleic acid (15% gel)*,† twice daily	Appears to be more effective than topical metronidazole but with more side effects, e.g., irritation Azeleic acid (20% cream twice daily) is a non–FDA-approved alternative dose
Sodium sulfacetamide (10%) and sulfur (5%) in a cream or lotion* once or twice daily	May include 10% urea
Erythromycin (2% solution) twice daily	Alcohol in solution may reduce tolerance
Clindamycin (1% lotion) daily	
Benzoyl peroxide 5% plus clindamycin 1% daily	May cause skin irritation
Tretinoin (0.025% cream; 0.05% cream; 0.01% gel) daily	Alters epidermal keratinization and may improve photodamage Poorly tolerated by some patients
Permethrin (5% cream) daily–weekly	Shown to be as effective as topical metronidazole for the treatment of papules and erythema May have future role in combination with antibiotics, but further studies needed
Pimecrolimus (1% cream) or tacrolimus (0.03%, 0.1% ointment) twice daily	Some studies have shown improvement in erythema, but there have been case reports of exacerbations, so further studies needed
Systemic	
Doxycycline*,†	40 mg daily (30 mg immediate release and 10 mg delayed release) for 4-8 weeks As effective as the 100 mg dose but with fewer adverse effects
Doxycycline	50-100 mg once or twice daily for 4-8 weeks
Minocycline	50-100 mg twice daily or sustained action formula (1 mg/kg) daily for 4-8 weeks**
Tetracycline†	250-500 mg twice daily for 4-8 weeks
Erythromycin	250-500 mg once or twice daily for 4-8 weeks
Azithromycin	250-500 mg (5-10 mg/kg) thrice weekly for 4-8 weeks
Metronidazole	200 mg once or twice daily for 4-8 weeks
Isotretinoin†	0.3 mg/kg/day
Phymatous	
Isotretinoin	May reduce nasal volume and halt the progression of rhinophyma
Surgical excision	Can effectively debulk and resculpt the nose
Electrosurgery	
CO_2 laser	
Ocular	
Eyelid hygiene and artificial tears	Frequently used to treat mild disease
Fusidic acid	Useful for maintaining remission following treatment of grades 2 and 3 disease with systemic antibiotics
Metronidazole gel	
Cyclosporine 0.5% ophthalmic emulsion†	More effective than artificial tears in treatment of ocular rosacea
Systemic antibiotics (see above section)	For grade 2-3 disease

If moderate to severe flushing persists despite avoidance of triggers, beta-blockers (e.g., carvedilol, nadolol) can be tried. *CO_2;* Carbon dioxide; *FDA,* U.S. Food and Drug Administration; *HCl,* hydrochloride; *UVR*, ultraviolet radiation.
*FDA-approved treatments for rosacea (evidence-based support = 1).
†In a Cochrane review of randomized controlled trials conducted for moderate to severe rosacea, these were the treatments shown to be effective.
**In a 16-week trial, minocycline 100 mg daily was noninferior to doxycycline 40 mg daily.
From Bolognia J: *Dermatology,* ed 4, 2018, Elsevier.

BASIC INFORMATION

DEFINITION

Roseola is a benign viral illness found in infants and characterized by high fevers that last 3 or 4 days, followed by defervescence, and development of a macular or maculopapular rash.

SYNONYMS

Exanthem subitum
Sixth disease
Roseola infantum
Pseudorubella
Human herpesvirus 6 (HHV-6), human herpesvirus 7 (HHV-7)

ICD-10CM CODE
B08.2 Exanthema subitum (sixth disease)

EPIDEMIOLOGY & DEMOGRAPHICS

- Nearly one-third of all infants develop roseola before the age of 2 yr.
- Peak prevalence is between 7 and 13 mo.
- More than 90% of children older than 2 yr of age are seropositive for the virus causing roseola.
- Roseola is spread from person to person. It is not known how it is spread, but it must be very efficiently spread and presumably via the respiratory tract.
- There is no predilection for gender or time of yr.
- Like other herpesviruses, HHV-6 induces a lifelong latent infection in humans.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typically the child develops a high fever, usually up to 104 °F (40 °C), that lasts for 3 to 5 days.
- Fever may be associated with a runny nose, irritability, and fatigue.
- A rash appears within 48 hr of defervescence; it begins on the neck or trunk and then spreads to the extremities, and persists for a few hours to 2 days.
- Faint pink maculopapular rash that blanches when palpated (Fig. E1) and generally nonpruritic. The mucous membranes are spared.
- Other common findings: Cervical and/or occipital adenopathy, erythematous tympanic membranes, anorexia.
- Nagayama spots: Red papules on the soft palate or base of the uvula.
- Seizures.
- Less common: Febrile seizures (≤6% of cases), cough, diarrhea, aseptic meningitis.

ETIOLOGY

- Roseola is usually caused by human herpesvirus-6 (HHV-6) in the great majority of cases but other causes include human herpesvirus-7, enteroviruses, adenoviruses, and parainfluenza virus type 1. A small percentage of children may have primary infection with HHV-7.
- The incubation period is between 5 and 15 days.

DIAGNOSIS

The diagnosis of roseola is usually made by the clinical presentation as stated previously. It can be confirmed serologically by indirect immunofluorescence assays, ELISA, neutralization assays, and immunoblot. Viral culture is the gold standard to document active viral replication but is expensive, time consuming, and available only in research laboratories.

DIFFERENTIAL DIAGNOSIS

- Rubeola (measles)
- Rubella
- Fifth disease (erythema infectiosum) caused by parvovirus B19
- Enteroviral infections
- Drug eruption
- Mononucleosis
- All causes of fever (e.g., otitis media, pneumonia, and urinary tract infection)
- Meningitis

WORKUP

- If unsure of the diagnosis of roseola in a febrile infant, a fever workup is done to rule out other infectious causes.
- The decision to proceed with a fever workup is a clinical judgment call.

LABORATORY TESTS

- CBC with differential usually shows relative neutropenia and mild atypical lymphocytosis
- Erythrocyte sedimentation rate (ESR), blood cultures as indicated
- Urinalysis and urine cultures
- Stool cultures if diarrhea is present
- Lumbar puncture if needed to rule out meningitis in patients with mental status changes
- Commercial assays can be used to detect HHV-6-specific IgG antibody responses but IgM assays are not always reliable for acute infection
- A quantitative PCR real-time assay for HHV-6 can be performed on whole blood, serum, plasma, or CSF and can be used to detect reactivation of latent virus in immunocompromised patients, such as hematopoietic stem cell transplant patients

IMAGING STUDIES

Chest x-ray to rule out pneumonia

TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive care
- Maintain hydration by drinking clear fluids: water, fruit juice, lemonade, and so forth
- Sponge bath with lukewarm water if febrile

ACUTE GENERAL Rx

- Acetaminophen 10 to 15 mg/kg per dose at 4-hr intervals for fever
- Ibuprofen 5 to 10 mg/kg per dose at 6-hr intervals (maximal dose 600 mg)

CHRONIC Rx

Roseola is a viral disease that is short lasting; chronic treatment is usually not an issue.

DISPOSITION

- Roseola is generally a benign, self-limited disease that usually lasts approximately 1 wk
- Complications, although rare, can occur and include:
  1. Febrile seizures
  2. Meningitis
  3. Encephalitis
  4. Pneumonitis
  5. Hepatitis

REFERRAL

Subspecialty consultation is made with the appropriate discipline if any of the previously mentioned complications occur (e.g., neurology for seizures).

PEARLS & CONSIDERATIONS

COMMENTS

- A child with fever and rash should be excluded from day care.
- HHV-6 is named accordingly because it is the sixth herpesvirus discovered after herpes simplex 1 (HSV-1), HSV-2, cytomegalovirus (CMV), Epstein-Barr virus (EBV), and varicella-zoster virus (VZV).
- Roseola is called sixth disease because it represents the sixth childhood "exanthem"; the other five are measles, scarlet fever, rubella, Dukes disease, and erythema infectiosum.
- Reactivation of latent virus in immunocompromised patients such as AIDS patients or hematopoietic stem cell or solid organ transplant recipients can be serious or fatal. In these patients, options include ganciclovir, foscarnet, and cidofovir.

FIG. E1 Roseola infantum. Erythematous blanching macules and papules **(A)** in an infant who had high fever for 3 days preceding development of the rash. On closer inspection **(B),** some lesions reveal a subtle peripheral halo of vasoconstriction. (From Paller AS, Mancinin AJ [eds]: *Hurwitz clinical pediatric dermatology,* ed 3, Philadelphia, 2006, Saunders.)

BASIC INFORMATION

DEFINITION

- The rotator cuff includes the supraspinatus, infraspinatus, teres minor, and subscapularis muscles that encompass the shoulder joint and facilitate both movement and stabilization of the joint.
- Rotator cuff disease is composed of subacromial bursitis, rotator cuff tendinopathy, impingement syndrome, and partial- or full-thickness muscle or tendon tears (Fig. E1).

SYNONYMS

Rotator cuff syndrome
Shoulder impingement syndrome
Painful arc syndrome
Supraspinatus syndrome

ICD-10CM CODES

M75.1	Rotator cuff tear or rupture, not specified as traumatic
M75.100	Unspecified rotator cuff tear or rupture of unspecified shoulder, not specified as traumatic
M75.11	Incomplete rotator cuff tear or rupture not specified as traumatic
M75.12	Complete rotator cuff tear or rupture, not specified as traumatic
M75.80	Other shoulder lesions, unspecified shoulder
M75.40	Impingement syndrome of unspecified shoulder
S46.001A	Unspecified injury of muscle(s) and tendon(s) of the rotator cuff of right shoulder, initial encounter
S46.002A	Unspecified injury of muscle(s) and tendon(s) of the rotator cuff of left shoulder, initial encounter
S43.421A	Sprain of right rotator cuff, initial encounter
S43.422A	Sprain of left rotator cuff capsule, initial encounter
S46.019A	Strain of muscle(s) and tendon(s) of the rotator cuff of unspecified shoulder, initial encounter
S46.099A	Other injury of muscle(s) and tendon(s) of the rotator cuff of unspecified shoulder, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 5% to 10% of the population. Can be prevalent in up to 39% of asymptomatic individuals with up to 64% prevalence in symptomatic individuals. Rotator cuff disease is the most common cause of shoulder pain, which is the third most frequent musculoskeletal reason to present to primary care. Up to 10% of all referrals to physical therapists are for shoulder pain.
PREDOMINANT SEX: Both sexes have been quoted as being equally predisposed to the development of rotator cuff pathology.
PREDOMINANT AGE: >40 yr. Advancing age has been consistently held accountable as a major risk factor for development of cuff tears.
RISK FACTORS: Advanced age, genetics, obesity, smoking and alcohol consumption, diabetes mellitus, repetitive overhead activity, occupational and sporting activities, trauma, and falls

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Pain located in the upper arm near the deltoid insertion and aggravated by overhead motions. Figs. E2 through E4 illustrate useful tests in the evaluation of rotator cuff disorders.
- Worse pain at night, exacerbated by lying on the affected shoulder.
- Muscle weakness indicates a tear.
- Atrophy and sunken appearance of the scapular muscles, especially infraspinatus, with longstanding disease.

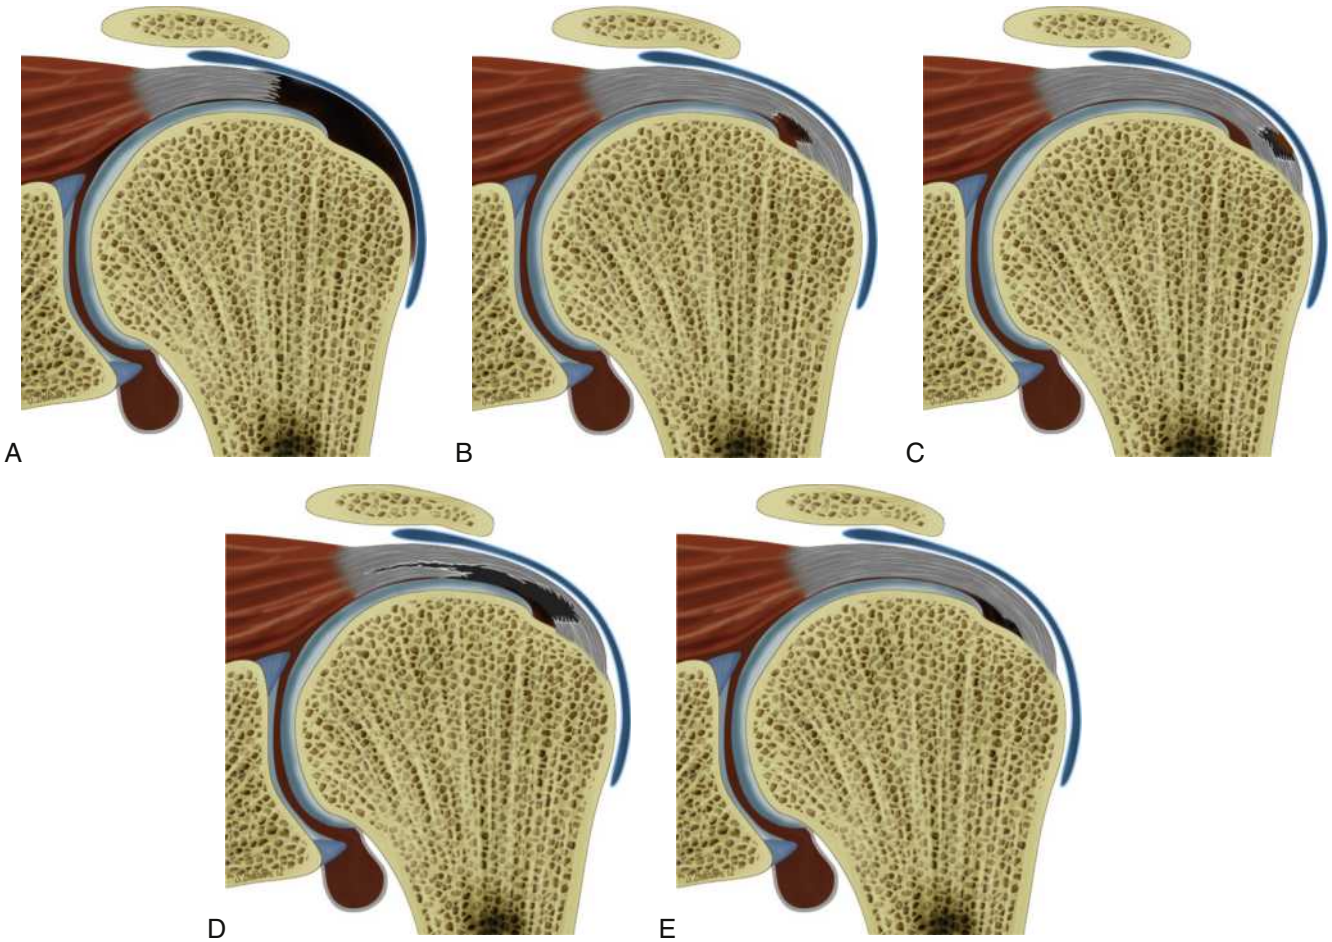

FIG. E1 Illustration of different types of rotator cuff tears. A, Full-thickness tear; **B,** partial articular surface tear; **C,** partial bursal surface tear; **D,** delaminating tear; **E,** rim-rent tear. (Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, WB Saunders.)

- Tenderness over the affected muscle or under the acromion suggests rotator cuff disease (Fig. E5).
- Useful clinical tests to assess for impingement include Hawkins-Kennedy sign, Neer sign, and the painful arc sign. The drop arm test is useful for evaluating for a rotator cuff tear.
- ***Hawkins-Kennedy sign:*** Shoulder and elbow are flexed at 90 degrees; shoulder pain is elicited with passive internal rotation.
- ***Neer sign:*** Pain with forced passive full-forward flexion.
- ***Painful arc sign:*** Pain with passive abduction of the shoulder between 60 and 120 degrees.
- ***Drop arm test:*** Examiner passively abducts patient's shoulder to 90 degrees. Patient is asked to slowly lower or adduct shoulder to their side. If patient is unable to control this motion, patient's arm falls to their side, suggesting a possible tear.
- Pain or weakness with resisted external rotation indicates involvement of the infraspinatus muscle.
- The combination of Hawkins-Kennedy sign, the painful arc sign, and weakness in external rotation yields the best probability (95%) for any degree of impingement.
- The combination of the drop arm sign, the painful arc sign, and weakness in external rotation accurately predicts full-thickness tears (91%).
- Studies suggest that a positive painful arc test result and a positive external rotation resistance test result are the most useful findings for detecting rotator cuff disease, whereas the presence of a positive lag test (external or internal rotation) is most useful for diagnosis of a full-thickness rotator cuff tear.
- A subacromial injection of local anesthetic can be used to distinguish weakness from rotator cuff tendinopathy and true tears—normal strength after injection indicates tendinopathy.

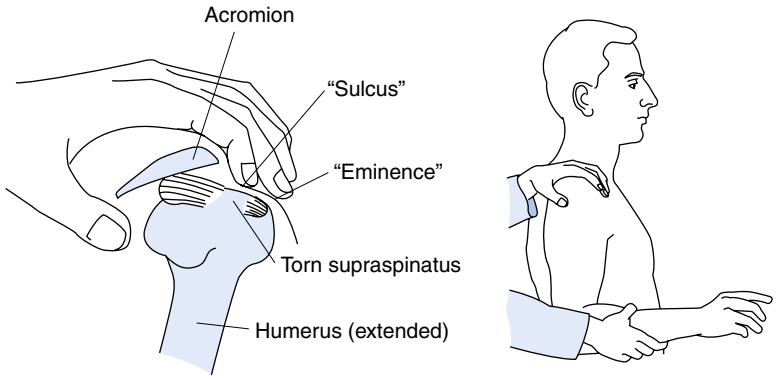

FIG. E2 Palpation of rotator cuff tears. The clinician stands behind the patient, and the patient's arm is relaxed at the side with the elbow flexed 90 degrees. The clinician palpates just below the patient's acromion with one hand and holds the patient's forearm with the other. The clinician then gently extends the patient's arm as far as possible and rotates the shoulder internally and externally to fully reveal the greater tuberosity and attached tissues. In patients with tears of the supraspinatus tendon (which inserts on the greater tuberosity), the clinician detects both an abnormal eminence and an abnormal sulcus posterior to this eminence. The abnormal eminence is the greater tuberosity with attached remnant of tendon, and the sulcus just behind it is the actual rent in the supraspinatus tendon. Comparison with the contralateral shoulder helps to determine whether the suspected tear is real or not. (From McGee S: *Evidence-based physical diagnosis*, ed 4, Philadelphia, 2018, Elsevier.)

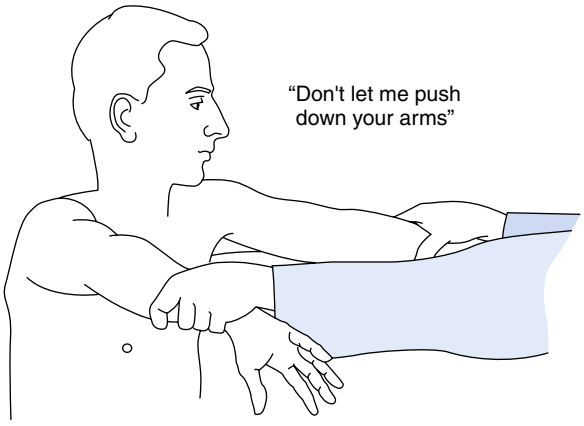

FIG. E3 Supraspinatus test (empty can test, Jobe test). The clinician stands in front of the patient and elevates the patient's arms to 90 degrees in the plane of the scapula (i.e., *scaption*, midway between forward flexion and sideways abduction). The patient's arms are internally rotated with thumbs pointing down (as if emptying a can). The patient is asked to hold this position and resist attempts to lower the arms to the side. Some investigators propose testing the supraspinatus muscle in a slightly different way, with the arms externally rotated and thumbs pointing up (i.e., **full can test**), because this position causes less pain than the empty can test. In clinical studies, both versions have similar diagnostic accuracy. (From McGee S: *Evidence-based physical diagnosis*, ed 4, Philadelphia, 2018, Elsevier.)

ETIOLOGY

A combination of tendon overload, microvascular compromise, and compression by surrounding structures. About 95% of all rotator cuff pathology occurs as an outcome from irritation onto the subacromial bursa and rotator cuff tendons from the undersurface of the overlying anterior aspect of the acromion. Recent studies show diabetes and hyperlipidemia may be associated with rotator cuff disease.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bicipital tendinitis, labrum tears, adhesive capsulitis, glenohumeral osteoarthritis, acromioclavicular injury, subscapularis bursitis, avascular necrosis. Table E1 describes the differential diagnosis of shoulder pain.
- Neurologic and visceral etiologies need to be ruled out.

IMAGING STUDIES

- Evidence-based guidelines do not support imaging for shoulder pain unless there is an indication of underlying pathology.
- Plain radiography: Anteroposterior view can reveal tendon calcifications and migration of humeral head, indicating a large tear.
- Ultrasonography: Accurate tool for initial evaluation, but has limitations as it is highly operator dependent; partial tears are difficult to identify.
- MRI (Fig. E6 and E7): Test of choice for shoulder soft tissue pathology when surgery is being considered. Lower sensitivity for partial tears, especially in the setting of severe osteoarthritis (OA).
- MRI arthrography: Useful when MRI is normal but a tear is clinically suspected. Better than MRI for picking up partial tears and labral tears. Can use CT arthrography instead if patient has a contraindication to an MRI.
- In-office needle arthroscopy has been shown in a recent systematic review to cost less but be diagnostically inferior to MRI for the diagnosis of rotator cuff tears.

Rx TREATMENT

ACUTE GENERAL Rx

- Ice and rest without aggravating activity.
- Physical therapy and a structured exercise program are unequivocally the main intervention for symptomatic rotator cuff pathology.
- Acetaminophen and/or topical or oral NSAIDs for 7 to 10 days, then as needed.
- Subacromial glucocorticoid injections (usually mixed with local anesthetic) can be used

in patients with severe pain and without suspected tears. Ultrasound-guided injection of an inflamed or thickened bursa has better outcomes.
- Intraarticular injections with hyaluronic acid in combination with physical therapy are more effective than physical therapy alone in reducing pain and improving function. However, the use of platelet-rich plasma injections in treating chronic rotator cuff tears may not be beneficial.
- Surgery is reserved for healthy patients with acute full-thickness tears or with chronic partial tears who fail conservative management. However, a recent systematic review showed subacromial decompression did not improve outcomes for painful shoulder impingement compared with placebo.

DISPOSITION

Return to work or sport should be gradual and based upon the ability to exhibit full range of motion (ROM) and appropriate strength without discomfort.

REFERRAL

- Physical therapy.
- Orthopedic consultation should be obtained in patients with a clinically significant rotator cuff tear and in patients who fail to improve with conservative management.

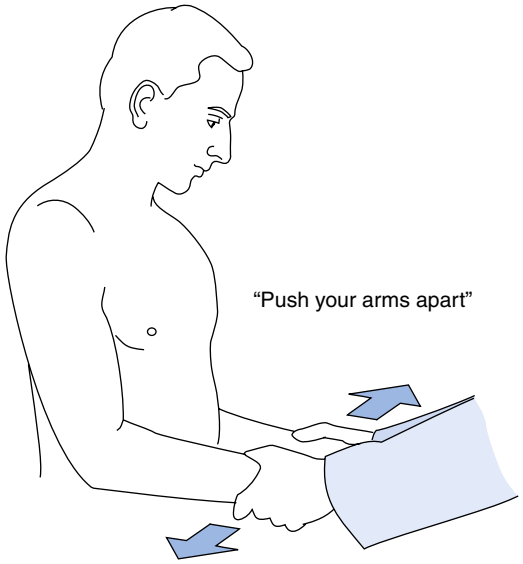

FIG. E4 Infraspinatus test. The clinician stands in front of the patient, and the patient's arms are at his or her side with elbows flexed 90 degrees and thumbs up. The examiner places his or her hands outside those of the patient's and directs the patient to move his arms out (i.e., direction of arrow), resisting the clinician's opposing inward pressure. (From McGee S: *Evidence-based physical diagnosis*, ed 4, Philadelphia, 2018, Elsevier.)

PEARLS & CONSIDERATIONS

COMMENTS

- Supraspinatus is the most commonly injured muscle.
- Rotator cuff tears can be asymptomatic, especially in the elderly.
- Identification of partial tears remains a clinical challenge, and imaging is often needed.
- It is important to differentiate tears from tendinopathy because they require different management.
- Most patients respond to conservative management. However, 50% of patients with shoulder pain have symptoms for over 6 mo.
- Untreated longstanding rotator cuff tendinopathy can cause significant loss in range of motion and adhesive capsulitis.

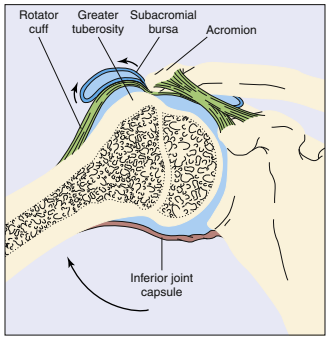

FIG. E5 Impingement of the rotator cuff and subacromial bursa. Mechanism of impingement of the rotator cuff and subacromial bursa between the humeral head and overlying coracoacromial arch. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

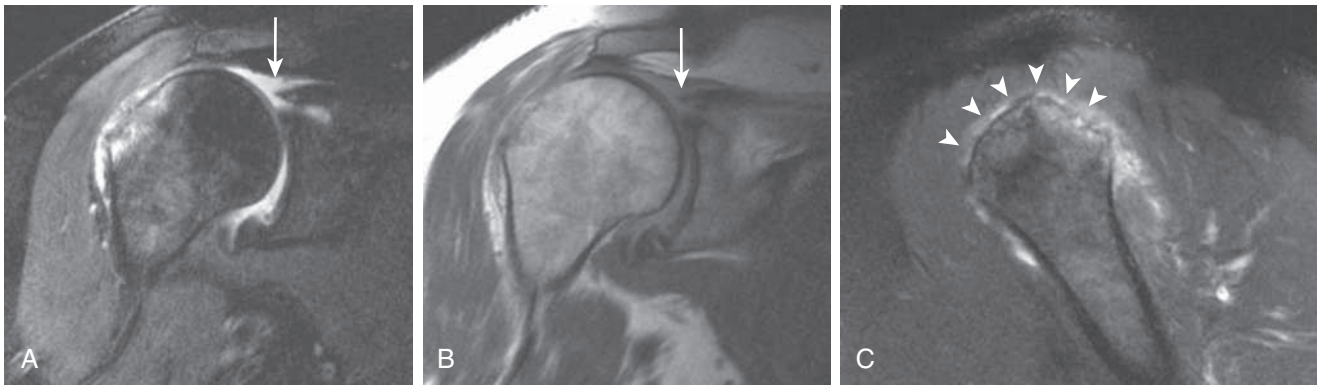

FIG. E7 Oblique coronal fat-suppressed proton density–weighted **(A),** oblique coronal proton density–weighted **(B),** and oblique sagittal fat-suppressed T2-weighted **(C)** magnetic resonance images demonstrate a massive full-thickness rotator cuff tear. Note the retraction of the myotendinous junction to the level of the glenoid (**A** and **B,** *arrows*). There is involvement of the entire supraspinatus and infraspinatus tendons as demonstrated by the complete stripping of the tendons from the greater tuberosity (**C,** *arrowheads*). Also note the markedly narrowed acromiohumeral interval. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, WB Saunders.)

- A recent trial showed that older patients with symptomatic, nontraumatic, supraspinatus tears do not benefit from surgery. Patients who underwent surgery and physiotherapy fared no better than those who underwent physiotherapy alone.

BASIC INFORMATION

DEFINITION

Rubella is a mild illness caused by the rubella virus that can cause severe congenital problems by in vitro transmission to a fetus when a pregnant woman becomes infected.

SYNONYM

German measles

ICD-10CM CODES

B06.9	Rubella without complication
B06	Rubella
B06.8	Rubella with other complications
P35.0	Congenital rubella syndrome
Z23	Encounter for immunization
B06.00	Rubella with neurological complication, unspecified
B06.01	Rubella encephalitis
B06.02	Rubella meningitis
B06.09	Other neurological complications of rubella
B06.81	Rubella pneumonia
B06.82	Rubella arthritis
B06.89	Other rubella complications
B06.9	Rubella without complication
Z20.4	Contact with and (suspected) exposure to rubella

EPIDEMIOLOGY & DEMOGRAPHICS

- Before vaccination (i.e., before 1969):
  1. 28 reported cases per 100,000 person-yr, eight of which were in persons >15 yr.
  2. Four cases of congenital rubella syndrome per 100,000 live births.
- Since mass vaccination (i.e., after 1980), most cases have occurred in unimmunized people, with <1 case per 100,000 person-yr (acquired and congenital) (Fig. E1).
- Currently, 10% to 20% of childbearing-age women are susceptible.
- The highest risk of developing long-term complications of congenital infection exists during the first trimester of gestation; both risk of congenital infection and long-term complications drop during the second trimester, and although the risk of congenital infection increases during the third trimester, there is no risk of long-term complication at that point.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acquired infection:
  1. Incubation: 14 to 21 days
  2. Prodrome: 1 to 5 days; low-grade fever, headache, malaise, anorexia, mild conjunctivitis, coryza, pharyngitis, cough, and cervical, suboccipital, and postauricular lymphadenopathy
  3. Rash: 1 to 5 days
- Enanthema: Palatal macules
- Exanthema (rash): Blotchy eruption beginning on face and neck (Fig. E2) and then spreading to trunk and limbs:
  1. Occasional splenomegaly and hepatitis (during rash)
  2. Complications: Arthritis (15%, mostly in adult women), thrombocytopenia, myocarditis, optic neuritis, encephalitis (all <0.1%)
- Congenital infection (see Table E1):
  1. Deafness: 85%
  2. Intrauterine growth retardation: 70%
  3. Cataracts: 35%
  4. Retinopathy: 35%
  5. Patent ductus arteriosus: 30%
  6. Pulmonary artery hypoplasia: 25%
  7. In utero death: 20%
  8. Mental retardation: 10% to 20%
  9. Meningoencephalitis: 10% to 20%
  10. Behavior disorder: 10% to 20%
  11. Hepatosplenomegaly: 10% to 20%
  12. Bone radiolucencies: 10% to 20%
  13. Diabetes mellitus (type 1): 10% to 20% by age 35 yr
  14. Other congenital heart defects: 2% to 5%

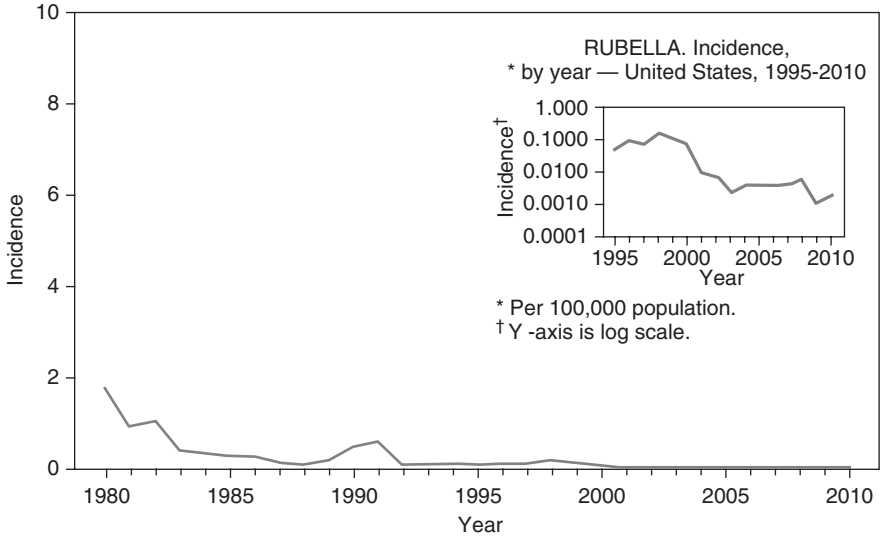

FIG. E1 Rubella. Incidence by yr in the U.S., 1980 through 2010. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, 2010, *MMWR* 59:1–111, 2012.)

ETIOLOGY & PATHOGENESIS

- Acquired infection:
  1. Viral portal of entry is upper respiratory tract.
  2. Viral replication occurs in lymph nodes; then hematogenous dissemination occurs to many organs, including placenta if present.
  3. Immune complexes may be cause of rash and arthritis.
- Congenital infection:
  1. Fetus is infected by the placenta during maternal-acquired infection.
  2. Cellular damage in the fetus results from cytolysis of fetal cells, mostly by fetal vasculitis or from immune-mediated inflammation and damage.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acquired rubella syndrome
  1. Other viral infections by enteroviruses, adenoviruses, human parvovirus B-19, measles
  2. Scarlet fever
  3. Allergic reaction
  4. Kawasaki syndrome
- Congenital rubella syndrome
  1. Congenital syphilis, toxoplasmosis, herpes simplex, cytomegalovirus, and enterovirus can cause a similar set of problems

WORKUP

- Acquired infection
  1. Serologic test (hemagglutination inhibition, neutralization tests, complement fixation tests, passive agglutination, enzyme immunoassay [EIA], enzyme-linked immunosorbent assay [ELISA])
  2. Immunoglobulin (Ig) M antibodies (by EIA) are detected early (by second to fourth week)
  3. IgG antibodies (by ELISA) can be measured as acute phase (7 days after rash onset) and convalescent phase (14 days later)
- Congenital infection
  1. Viral culture (from nasopharynx)
  2. Serologic studies: IgM anti–rubella virus detection by EIA is the method of choice (after the newborn is age 5 mo)

IMMUNIZATION

- Four existing vaccines provide persisting immunity in 92% of vaccines. Indications:
  1. All children ≥12 mo (as part of the measles-mumps-rubella [MMR] vaccine)
  2. Postpubertal women
- Vaccinate if not known to be immunized (advise not to become pregnant within 3 mo of vaccination)
- Premarital serologic screening for rubella immunity

FIG. E2 Rash of rubella. (From Kliegman RM et al: *Nelson textbook of pediatrics*, ed 19, Philadelphia, 2011, Saunders.)

TABLE E1 Pathologic Findings in Congenital Rubella Syndrome

System	Pathologic
Cardiovascular	Patent ductus arteriosus Pulmonary artery stenosis Ventriculoseptal defect Myocarditis
Central nervous system	Chronic meningitis Parenchymal necrosis Vasculitis with calcification
Eye	Microphthalmia Cataract Iridocyclitis Ciliary body necrosis Glaucoma Retinopathy
Ear	Cochlear hemorrhage Endothelial necrosis
Lung	Chronic mononuclear interstitial pneumonitis
Liver	Hepatic giant cell transformation Fibrosis Lobular disarray Bile stasis
Kidney	Interstitial nephritis
Adrenal gland	Cortical cytomegaly
Bone	Malformed osteoid Poor mineralization of osteoid Thinning cartilage
Spleen, lymph node	Extramedullary hematopoiesis
Thymus	Histiocytic reaction Absence of germinal centers
Skin	Erythropoiesis in dermis

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

- Prenatal or antepartum serologic screening for rubella
- Vaccinate susceptible women postpartum
- Serologic screening for female workers likely to be exposed to rubella (e.g., teachers, child-care employees, health care workers)

CONTRAINDICATIONS

- Pregnancy
- Recent receipt of immune globulin or blood transfusion (2 wk before to 3 mo after)
- Immunodeficiency (except AIDS)
- Adverse reactions:
  1. Fever, rash, or lymphadenopathy: 5% to 15%
  2. Arthralgias: 0.5% in children; 25% in adult women
  3. Transient peripheral neuropathy (rare)

Rx TREATMENT

- No known effective antiviral therapy
- Management of specific congenital problems as appropriate

RELATED CONTENT

Rubella (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Salivary gland neoplasms are benign or malignant tumors of the salivary glands (parotid, submandibular, or sublingual).

SYNONYMS

These tumors are often named according to their histologic type (see "Diagnosis").

ICD-10CM CODES

C08.9	Malignant neoplasm of major salivary gland, unspecified
C07	Malignant neoplasm of parotid gland
C08.0	Malignant neoplasm of submandibular gland
C08.1	Malignant neoplasm of sublingual gland

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: One to two cases per 100,000 person-yr (1% of all head and neck tumors)

RISK FACTORS:

- The causes are not fully understood.
- Prior radiation, cancer history, and genetic predisposition may play a role.
- Workers involved in rubber manufacturing and beauty shops and those with exposure to nickel compounds may have an increased risk of salivary gland cancers.
- Chronic inflammation of salivary glands is not clearly defined as a risk factor.

DISTRIBUTION:

- Parotid gland, 85% (80% are benign)
- Submandibular gland, 10% (55% are benign)
- Sublingual and minor glands, 5% (35% are benign)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Parotid gland:
  1. Painless swelling overlying the masseter muscle (under the temporomandibular joint)
  2. Pain
  3. Facial nerve palsy
  4. Cervical lymph nodes
  5. Mass in oral cavity
- Submandibular gland: Swelling under anterior portion of the mandible.
- Sublingual gland: Intraoral swelling under the tongue, medial to the mandible.
- Initial spread is by local invasion. Parotid tumors present fixation to surrounding structures in approximately 20% of cases, skin invasion in 10%, and facial nerve involvement in 25%.
- Neck lymph node metastases are more common in the submandibular gland than in the parotid gland, about 40% vs. 25%, respectively.
- Distant metastases at presentation are rare. At 10 yr they account for approximately 30% to 40%, primarily depending on histologic type (adenoid cystic carcinoma, squamous cell, undifferentiated, and salivary duct carcinoma). Lung and bone are the most common sites, depending on histologic type.
- Lung and bone are the most common sites of metastasis.
- Risk factors for recurrence postoperatively include locally advanced tumor, pathologic T_3-T_4 stage, invasion into adjacent structures, nodal involvement, high-grade histology, perineural invasion, angiolymphatic invasion, positive margins, and recurrent disease.

ETIOLOGY AND PATHOGENESIS:

- Several salivary gland tumors are characterized by tumor-type–specific gene fusions. The major targets of the translocations are transcriptional coactivators, tyrosine kinase receptors, and transcription factors involved in growth factor signaling and cell cycle regulation.
- Adenoid cystic carcinoma (ACC) is characterized in more than 80% cases by a t(6;9)(q22–23;p23–24) translocation, resulting in a fusion of the *MYB* oncogene to the transcription factor gene *NFIB. MYB* is a transcription factor involved in the control of cell proliferation, apoptosis, and differentiation that is highly expressed in immature, proliferating cells and is downregulated as cells become differentiated.
- Mucoepidermoid carcinoma (MEC), the most common subtype, is characterized by a t(11;19)(q21–22;p13) translocation, resulting in a *CRTC1-MAML2* gene fusion. The fusion oncoprotein has transforming activity and activates transcription of several target genes.

DIAGNOSIS

PATHOLOGY

HISTORY

Benign Tumors:

- Mixed tumor (usually parotid)
- Adenolymphoma (Warthin tumor)
- Pleomorphic adenoma
- Capillary hemangioma, lymphangioma (in children)
- Intraductal papilloma
- Other (e.g., myoepithelioma, canalicular adenoma, basal cell adenoma)

Malignant Tumors:

- Mucoepidermoid carcinoma (most common malignant tumor of the parotid gland)
- Adenoid cystic carcinoma
- Adenocarcinoma
- Malignant mixed tumor
- Squamous cell carcinoma
- Other

STAGE (TNM):

T_0	No evidence of primary tumor
T_1	Tumor <2 cm
T_2	Tumor 2-4 cm
T_3	Tumor 4-6 cm
T_4	Tumor >6 cm

All subdivided into:

- Without local extension
- With local extension

N_0	No lymph node metastasis
N_1	Single ipsilateral node <3 cm
N_2	Ipsilateral, contralateral, or bilateral node <6 cm
N_3	Any node >6 cm
M_0	No distant metastasis
M_1	Distant metastasis
Stage I	T_{1a} or $_{2a}N_0M_0$
Stage II	$T_{1b,2b,3a}$ N_0M_0
Stage III	$T_{3b,4a}$ N_0M_0 or any T except $_{4b}N_1M_0$
Stage IV	T_{4b} N any M any or T any $N_{2,3}M_0$ or T any N_1M_1

WORKUP

- Fine-needle aspiration. The sensitivity, specificity, and accuracy of parotid gland aspirates are approximately 92%, 100%, and 98%, respectively
- Imaging by CT scan or MRI (Fig. E1)
- Open biopsy (rarely indicated)

TREATMENT

Malignant tumors:

- Surgery is the mainstay of treatment; gland resection and neck dissection if lymph nodes are involved is the standard approach.
- A lateral lobectomy with preservation of facial nerve should be considered for tumors confined to the superficial lobe of the parotid gland. Gross tumor should not be left in situ, but if the facial nerve is able to be preserved by "peeling" tumor off the nerve, it should be

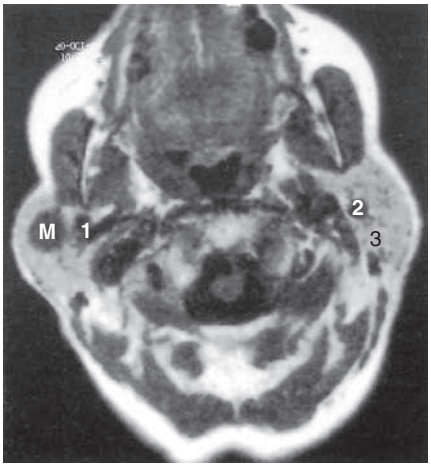

FIG. E1 Pleomorphic adenoma of parotid gland. Pleomorphic adenoma in the right parotid *(M)* is a well-defined, low-signal intensity mass on the axial T1-weighted MRI. Note displacement of the retromandibular vein *(1)* medially by the mass compared with the normal left retromandibular vein *(2).* The left facial nerve *(3)* branching through the normal left parotid is seen. (From Skarin AT: *Atlas of diagnostic oncology,* ed 4, St Louis, 2010, Mosby.)

attempted, followed by radiation therapy for microscopic disease.
- Postoperative radiotherapy is indicated for high-risk malignant tumors and has demonstrated improved overall survival.
- Cisplatin chemotherapy can be considered in combination with radiotherapy for high-risk or unresectable disease.
- Single-agent chemotherapy (cisplatin, doxorubicin, methotrexate, taxanes) or multiagent regimens can be used if metastatic spread-through response rates are low.
- The immune checkpoint inhibitor pembrolizumab has demonstrated promising antitumor activity and a manageable safety profile in patients with advanced salivary gland cancers.

Targeted therapies targeting EGFR (cetuximab) and c-kit (imatinib) have been evaluated with limited efficacy in metastatic patients.

PROGNOSIS OF MALIGNANT TUMORS

Five-yr survival rates:
- Mucoepidermoid carcinoma: 75% to 95%
- Adenoid cystic carcinoma: 40% to 80%
- Adenocarcinoma: 20% to 75%
- Malignant mixed tumor: 35% to 75%
- Squamous cell carcinoma: 25% to 60%

BASIC INFORMATION

DEFINITION

Salmonellosis is an infection caused by one of several serotypes of a gram-negative bacillus of the genus *Salmonella.* Salmonella infection can be typhoidal (serotype Typhi or Paratyphi) or nontyphoidal. Current *Salmonella* nomenclature is described in Table 1.

SYNONYMS

Typhoid fever
Paratyphoid fever
Enteric fever

ICD-10CM CODES

A02.0	*Salmonella* enteritis
A02.1	*Salmonella* sepsis
A02.2	Localized *Salmonella* infections
A02.8	Other specified *Salmonella* infections
A0.9	*Salmonella* infection, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Epidemiologically, the clinical syndromes are divided into those that cause a typhoidal type of infection (systemic illness with fever and abdominal pain) such as *Salmonella typhi* and those that do not: Nontyphoidal *Salmonella* infections (gastroenteritis) such as *S. enteritidis*, *S. newport*, and *S. typhimurium.*
- Estimated 1 million cases/yr of nontyphoidal salmonellosis in the United States (leading cause of foodborne illness in the U.S.). In 2017 an outbreak occurred linked to live poultry in backyard flocks with over 960 cases in 48 states caused by several different *Salmonella* bacteria.
- Largest outbreak of gastroenteritis syndrome (nontyphoidal): 200,000 who ingested contaminated milk.
- Approximately 500 cases of *Salmonella typhi* infection are reported each yr, of which nearly 80% is associated with foreign travel.

PREDOMINANT AGE:

- <20 yr old
- >70 yr old
- Highest rates of infection in infants, especially neonates

PEAK INCIDENCE: Summer and fall

GENETICS:

Neonatal Infection:

- Highly susceptible to infection with nontyphoidal *Salmonella*

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Infections:
  1. Localized to GI tract (gastroenteritis)
  2. Systemic (typhoid fever)
  3. Localized outside of GI tract
- Gastroenteritis:
  1. Incubation period: 12 to 48 hr
  2. Nausea, vomiting
  3. Diarrhea, abdominal cramps
  4. Fever
  5. Bacteremia: Occurs mostly in the immunocompromised host or those with underlying conditions, including HIV infection
  6. Self-limited illness lasting 3 or 4 days
  7. Colonization of GI tract persistent for months, especially in those treated with antibiotics
- Typhoid fever:
  1. Incubation period of few days to several wk
  2. Prolonged fever, often with a stepwise-increasing temperature pattern
  3. Myalgias
  4. Headache, cough, sore throat
  5. Malaise, anorexia
  6. Abdominal pain
  7. Hepatosplenomegaly
  8. Diarrhea or constipation early in the course of illness
  9. Rose spots (faint, maculopapular, blanching lesions) sometimes seen on chest or abdomen
- Untreated disease:
  1. Fever lasting 1 to 2 mo
  2. Main complication: GI bleeding caused by perforation from ulceration of Peyer patches in the ileum
  3. Rare complications:
     a. Mental status changes
     b. Shock
  4. Relapse rate of approximately 10%
- Infections outside GI tract:
  1. Can occur in virtually any location
  2. Usually occur in patients with underlying diseases
  3. Endocarditis, endovascular infections are caused by seeding of atherosclerotic plaques or aneurysms
  4. Hepatic or splenic abscesses in patients with underlying disease in these organs
  5. Urinary tract infections in patients with renal tuberculosis (TB) or schistosomiasis
  6. *Salmonellae* are a frequent cause of gram-negative meningitis in neonates
  7. Osteomyelitis in children with hemoglobinopathies (particularly sickle cell disease)

ETIOLOGY

- More than 2000 serotypes of *Salmonella* exist, but only a few cause disease in humans. Host factors and conditions predisposing to the development of systemic disease with nontyphoidal *Salmonella* strains are described in Table 2 and Table 3.
- Raw produce is an increasingly recognized vehicle for salmonellosis. In 2008 there was a large outbreak due to contaminated jalapeno and Serrano peppers with *Salmonella Saintpaul* involving 1500 persons, of whom 21% were hospitalized and two died. In 2009 there was an outbreak associated with contaminated peanut butter and peanuts. In 2017 there was an outbreak associated with papaya.
- Some found only in humans are the cause of enteric fever:
  1. *S. typhi*
  2. *S. paratyphi*
- Some responsible for gastroenteritis and frequently isolated from raw meat and poultry and uncooked or undercooked eggs:
  1. *S. typhimurium*
  2. *S. enteritidis*
- *S. choleraesuis* is a prototype organism that causes extraintestinal nontyphoidal disease.
- Transmission generally via ingestion of contaminated food or drink.
- Outbreaks of gastroenteritis related to contaminated poultry, meat, and dairy products are common.
- Typhoid fever is a systemic illness caused by serotypes exclusive to humans:
  1. Acquisition by ingestion of food or water contaminated by other humans.
  2. Most cases in the United States are:

TABLE 1 *Salmonella* Nomenclature

Traditional Usage	Formal Name	CDC Designation
S. typhi	*S. enterica** subsp. enterica ser. Typhi	*S.* ser. Typhi
S. dublin	*S. enterica* subsp. enterica ser. Dublin	*S.* ser. Dublin
S. typhimurium	*S. enterica* subsp. enterica ser. Typhimurium	*S.* ser. Typhimurium
S. choleraesuis	*S. enterica* subsp. enterica ser. Choleraesuis	*S.* ser. Choleraesuis
S. marina	*S. enterica* subsp. houtenae ser. Marina	*S.* ser. Marina

CDC, Centers for Disease Control and Prevention; *ser.,* serovar; *subsp.,* subspecies.
*Some authorities prefer *S. choleraesuis* or *S. enteritidis* rather than *S. enterica* to describe the species.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

TABLE 2 Host Factors and Conditions Predisposing to the Development of Systemic Disease with Nontyphoidal *Salmonella* Strains

Neonates and young infants (≤3 mo of age)
HIV/AIDS
Other immunodeficiencies and chronic granulomatous disease
Immunosuppressive and corticosteroid therapies
Malignancies, especially leukemia and lymphoma
Hemolytic anemia, including sickle cell disease, malaria, and bartonellosis
Collagen vascular disease
Inflammatory bowel disease
Achlorhydria or use of antacid medications
Impaired intestinal motility
Schistosomiasis, malaria
Malnutrition

AIDS, Acquired immunodeficiency syndrome; *HIV,* human immunodeficiency virus.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

TABLE 3 Susceptibility to *Salmonella* spp. Infection

Patient Group at Risk	Mechanism
Newborn	Achlorhydria, rapid gastric emptying
	Poorly developed cell-mediated immunity
	Complement deficiency
	Immunoglobulin deficiency in premature infants
Sickle-cell anemia	Reticuloendothelial system overload owing to hemolysis
	Functional asplenia
	Tissue infarcts
	Defective opsonization
Neutropenia (congenital or acquired)	Polymorphonuclear neutrophils needed for killing
Chronic granulomatous disease	Defective killing by polymorphonuclear neutrophils
Defects of immune system IL-12/interferon-γ axis	Defective signaling resulting in failure to activate macrophages and recurrent/persistent infection by nontyphoid *Salmonella*
Acquired immunodeficiency syndrome	Low CD4
	Effects of malnutrition on cell-mediated immunity
	Survival of organisms in macrophages (owing to *Salmonella* genes *PhoP/PhoQ, spvA-D, R*)
Organ transplantation, immunosuppression	Defective cell-mediated immunity
Gastrectomy	Loss of stomach acid barrier
Malaria	Reticuloendothelial overload during hemolysis
	Abnormal complement levels
	Abnormal macrophage function
Bartonellosis (verruga peruana)	Reticuloendothelial overload during hemolysis
Schistosomiasis	*Salmonella* sequestered in schistosomes protected from host defenses and antibiotics

From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

   a. Acquired during foreign travel: 80% of cases.
   b. Acquired by ingestion of food prepared by chronic carriers, many of whom have acquired the organism outside of the United States.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of prolonged fever:
  1. Malaria
  2. TB
  3. Brucellosis
  4. Amebic liver abscess
- Other causes of gastroenteritis:
  1. Bacterial: *Shigella, Yersinia, Campylobacter* spp.
  2. Viral: Norwalk virus, rotavirus
  3. Parasitic: *Entamoeba histolytica, Giardia lamblia*
  4. Toxic: *Enterotoxigenic E. coli, Clostridium difficile*

WORKUP

- Typhoid fever:
  1. Cultures of blood, stool, urine; repeat if initially negative.
  2. Blood cultures are more likely to be positive early in the course of illness.
  3. Stool and urine cultures are more commonly positive in the second and third wk of illness.
  4. Highest yield with bone marrow biopsy cultures: 90% positive.
  5. Serology using Widal test is helpful in retrospect, showing a fourfold increase in convalescent titers.
- Gastroenteritis: Stool cultures
- Extraintestinal localized infection:
  1. Blood cultures.
  2. Cultures from the site of infection.

LABORATORY TESTS

- Neutropenia is common.
- Transaminitis is possible.
- Culture to grow organism: Blood, body fluids, biopsy specimens.

IMAGING STUDIES

- Not routinely indicated.
- Radiographs of bone may be suggestive of osteomyelitis (particularly in patients with sickle cell disease and bone infarctions).
- CT scan or sonogram of abdomen:
  1. May reveal hepatic or splenic abscesses or pleural involvement.
  2. May reveal aortic aneurysm.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Adequate hydration and electrolyte replacement in people with diarrhea.

TABLE 4 Treatment of Salmonella Gastroenteritis in Children

Organism and Indication	Dose and Duration of Treatment
Salmonella infections in infants <3 mo of age or immunocompromised persons (in addition to appropriate treatment for underlying disorder)	Cefotaxime 100-200 mg/kg/day every 6 hr for 5-14 days *or* Ceftriaxone 75 mg/kg/day once daily for 7 days *or* Ampicillin 100 mg/kg/day every 6 hr for 7 days *or* Cefixime 15 mg/kg/day for 7-10 days

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

ACUTE GENERAL Rx

Treatment decisions must consider the severity of infection and the risk for extraintestinal disease.

- Typhoid fever:
  1. Levofloxacin 750 mg PO/IV q24h or ciprofloxacin 500 mg PO bid or 400 mg IV bid for 7 to 10 days. Should not be used as first line in patients from South Asia due to resistance unless known to be susceptible
  2. Ceftriaxone 2 g IV qd for 7 to 14 days or cefixime (20 to 30 mg/kg/day orally divided into q12h dosing for 7 to 14 days)
  3. Another alternative agent: Azithromycin (1 g orally then 500 mg daily for 5 to 7 days)
  4. Children: See Table 4. In general, quinolones are avoided in children unless a multidrug-resistant strain is involved due to concerns of possible cartilage damage. Another alternative for children: Azithromycin (10 to 20 mg/kg to 1 g maximum once daily for 5 to 7 days)
  5. If tests show susceptibility, can also use amoxicillin or trimethoprim/sulfamethoxazole in adults and children (Table 5)
  6. Dexamethasone 3 mg IV initially, followed by 1 mg IV q6h for eight doses for patients with shock or mental status changes
- Gastroenteritis:
  1. Usually not indicated for gastroenteritis alone because this illness usually self-limited
  2. Treatment may prolong the carrier state and is discouraged for healthy patients <50 yr of age who have relatively mild disease
  3. Prophylactic treatment for patients who are at high risk of developing complications from bacteremia (see Table 4):
     a. Neonates
     b. Patients with hemoglobinopathies
     c. Patients with atherosclerosis
     d. Patients with aneurysms
     e. Patients with prosthetic devices
     f. Immunocompromised patients

TABLE 5 Antibiotics Commonly Used in the Treatment of *Salmonella* Infections

Drug	Dose	Comments
Ciprofloxacin	20-30 mg/kg per day in 2 doses PO or IV	First-line therapy[a]
Ceftriaxone	75-100 mg/kg per day in 1 or 2 doses IM or IV	First-line therapy
Cefotaxime	100-300 mg/kg per day in 3-4 doses IM or IV	First-line therapy
Cefixime	20-30 mg/kg per day in 1 or 2 doses PO	Alternative therapy
Azithromycin	10 mg/kg per day in 1 dose PO	Alternative therapy
Chloramphenicol	50-100 mg/kg per day in 4 doses PO	High frequency of resistance; use only for susceptible strains
Ampicillin	200-400 mg/kg per day in 4 doses PO, IM, or IV	High frequency of resistance; use only for susceptible strains
TMP-SMX	10 mg/kg per day TMP, 50 mg/kg per day SMX in 2 doses PO or IV	High frequency of resistance; use only for susceptible strains

IM, Intramuscular; *IV,* intravenous; *PO,* by mouth; *TMP-SMX,* trimethoprim-sulfamethoxazole.
[a]Not approved by the US Food and Drug Administration in children <18 yr; current expert opinion agrees in recommending this agent as an effective therapy for regions with susceptible *Salmonella* strains and especially for severe infections.
From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

CHRONIC Rx

- Carrier states are possible in those with typhoid fever.
- More common in people >60 yr of age and in people with gallstones.
- Usual site of colonization is the gallbladder.
- Treatment should be considered for those with persistently positive stool cultures and for food handlers.
- Suggested regimens for eradication of carrier state:
  1. Ciprofloxacin 500 mg PO bid for 4 wk.
  2. SMX/TMP 1 to 2 DS tabs PO bid for 6 wk (if susceptible).
  3. Amoxicillin 2 g PO q8h for 6 wk (if susceptible).
- Cholecystectomy may be required in carriers with gallstones who fail medical therapy, but this is rarely indicated for nontyphoidal salmonellosis currently.
- Prolonged course of oral therapy or lifetime suppression for patients with AIDS who have chronic infection.

DISPOSITION

- Typhoid fever:
  1. Treated patients usually respond to therapy; small percentage of chronic carriers.
  2. Untreated patients may have serious complications.
- Gastroenteritis:
  1. Usually self-limited
  2. May be recurrent or persistent in AIDS patients

PEARLS & CONSIDERATIONS

COMMENTS

- Fluoroquinolones remain the most reliably effective class of antibiotics for empiric therapy despite increasing resistance. They should not be used in children or pregnant women.
- Infections should be reported to local health departments.
- Other recent outbreaks in the U.S. have been traced back to raw tomatoes, peanut butter, pet turtles, and frozen pot pies.
- Vaccine is available for *Salmonella typhi*: Oral live weakened vaccine (four doses, one every other day) for age >6 yr and lasts for 5 yr or one dose of inactivated injectable vaccine for persons >2 yr old that lasts for 2 yr, but neither vaccine is greater than 75% effective.

BASIC INFORMATION

BASIC INFORMATION

Sarcoidosis is a chronic multisystem granulomatous disease characterized histologically by the presence of nonspecific, noncaseating granulomas.

SYNONYM

Boeck sarcoid

ICD-10CM CODES

D86	Sarcoidosis
D86.0	Sarcoidosis of lung
D86.1	Sarcoidosis of lymph nodes
D86.2	Sarcoidosis of lung with sarcoidosis of lymph nodes
D86.3	Sarcoidosis of skin
D86.8	Sarcoidosis of other and combined sites
D86.9	Sarcoidosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Incidence is 11 in 100,000 in whites and 35 in 100,000 in blacks; presents most commonly in the winter and early spring. (The adjusted annual incidence among black Americans is roughly three times higher than among white Americans [35.5 cases/100,000, as compared with 10.9/100,000] and is likely more chronic and fatal in black Americans.)

PREDOMINANT SEX: Increased incidence in females

PREDOMINANT AGE: 20 to 40 yr

GENETICS: Familial clustering has been described. Having a first-degree relative with sarcoidosis increases the risk for disease fivefold (ACCESS study). There have been reports of association between sarcoidosis and gene products, specifically HLA class II antigens, encoded by HLA-DRB1 and DQB1 alleles.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical manifestations often vary with the stage of the disease and degree of organ involvement. Patients may be asymptomatic, but a chest radiograph may demonstrate findings consistent with sarcoidosis (see "Imaging Studies"). Nearly 50% of patients with sarcoidosis are diagnosed by incidental findings on chest radiograph. Lung involvement occurs in >90% of patients with sarcoidosis.
- Frequent manifestations:
  1. Pulmonary manifestations: Dry, nonproductive cough; dyspnea; chest discomfort.
  2. Constitutional symptoms: Fatigue, weight loss, anorexia, malaise, night sweats.
  3. Visual disturbances: Blurred vision, ocular discomfort, conjunctivitis, iritis, uveitis (65% of patients).
  4. Dermatologic manifestations (30% of patients): Erythema nodosum (10% of patients), macules, papules, subcutaneous nodules, hyperpigmentation, lupus pernio (indurated violaceous lesions on the nose, lips, ears, and cheeks that can erode into underlying cartilage and bone) (Fig. E1).
  5. Myocardial disturbances, arrhythmias, cardiomyopathy, various conduction abnormalities, and pericardial effusion. Cardiac sarcoidosis is much more common than clinically appreciated and is found in up to 25% of patients in the U.S.
  6. Splenomegaly, hepatomegaly.
  7. Rheumatologic manifestations: Arthralgias have been reported in up to 40% of patients. It typically affects the ankles but can also involve the knees, wrists, and small joints of the hands and feet.
  8. Löfgren syndrome, consisting of triad of arthritis, erythema nodosum, and bilateral hilar adenopathy, occurs in 9% to 34% of patients. Fever is frequently present.
  9. Neurologic and other manifestations: Cranial nerve palsies, diabetes insipidus, meningeal involvement, parotid enlargement, hypothalamic and pituitary lesions, peripheral adenopathy. Neurosarcoidosis is detected in up to 25% of patients and can occur in the absence of apparent disease elsewhere. The presence of anterior uveitis, parotiditis, fevers, and facial nerve palsy is known as Heerfordt syndrome.

ETIOLOGY & PATHOGENESIS

A cardinal feature of sarcoidosis is the presence of CD4+ T cells that interact with antigen-presenting cells to initiate the formation and maintenance of granulomas (Fig. 2). Multiple lines of evidence suggest that sarcoidosis may result from the interaction of multiple genes with environmental exposures or infection.

GENETIC PREDISPOSITION TO SARCOIDOSIS

Various HLA antigens have been implicated in diverse patient populations. Familial predisposition has been reported dating back to 1923, with a wide percentage of variability of affected relatives (0.4% to 21%) and heterogeneity based on genetic background. A more recent study was published by the ACCESS (A Case Controlled Etiologic Survey of Sarcoidosis) study group, which confirmed increased risk for family members with an odds ratio of 4.6 for all relatives. Absolute risk, however, for a family member to be affected was less than 1%. This study also showed a higher risk in white versus African-American siblings and parents.

IMMUNOPATHOGENESIS OF SARCOIDOSIS: Numerous chemokines and cytokines have been implicated in the development and/or resolution of the disease. In sarcoidosis, the alveolitis seen at disease presentation represents an increase in primarily lymphocytic cellularity, predominated by CD4 cells. Presence of increased neutrophils in the bronchoalveolar lavage of patients with sarcoidosis has been associated with persistence of disease, with spontaneous remission noted in 36% of patients with elevated neutrophil counts. Other interstitial lung diseases in which neutrophils have been associated with worse outcomes include interstitial pulmonary fibrosis hypersensitivity pneumonitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Tuberculosis
- Lymphoma
- Hodgkin disease
- Metastases
- Pneumoconioses
- Enlarged pulmonary arteries
- Infectious mononucleosis
- Lymphangitic carcinomatosis
- Idiopathic hemosiderosis
- Alveolar cell carcinoma
- Pulmonary eosinophilia
- Hypersensitivity pneumonitis
- Fibrosing alveolitis
- Collagen disorders
- Parasitic infection

Section II describes the differential diagnosis of granulomatous lung disease and a classification of granulomatous disorders.

WORKUP

- No pathognomonic diagnostic test exists for sarcoidosis, so the diagnosis remains one of exclusion. Workup is aimed at excluding critical organ involvement, determining extent and severity of disease, and excluding other disease. The presence of noncaseating granulomas does not establish the diagnosis, because conditions such as tuberculosis and malignancies, among others, can cause granulomas. A complete neurologic and ophthalmologic examination is mandatory. A complete occupational and environmental exposure history is recommended.
- Initial laboratory evaluation should include complete blood count, serum chemistries (alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, electrolytes, blood urea nitrogen, creatinine, serum calcium), urinalysis, 24-hour urinary excretion of calcium, CRP, ESR, and tuberculin skin test.
- Chest radiograph and ECG should also be obtained in all patients with sarcoidosis.
- Pulmonary function testing: Spirometry, diffusion capacity of carbon monoxide–single breath.
- Biopsy should be done on accessible tissues suspected of sarcoid involvement (conjunctiva, skin, lymph nodes); bronchoscopy with transbronchial biopsy (85% diagnostic yield) is often performed in patients without any readily accessible site. Endobronchial ultrasound-guided fine-needle aspiration of intrathoracic lymph nodes also has high diagnostic yield and makes use of mediastinoscopy usually unnecessary. Among patients with suspected Stage I/II pulmonary sarcoidosis undergoing tissue confirmation, the use of endosonographic nodal aspiration compared with bronchoscopic biopsy resulted in greater diagnostic yield.

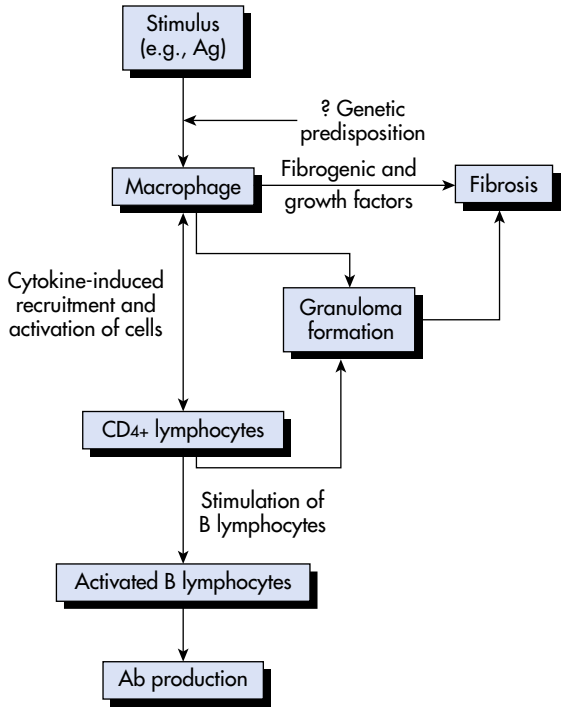

FIG. 2 Simplified proposed pathogenetic sequence in sarcoidosis. *Ab*, Antibody; *Ag*, antigen. (From Weinberger SE: *Principles of pulmonary medicine*, ed 7, Philadelphia, 2019, Elsevier.)

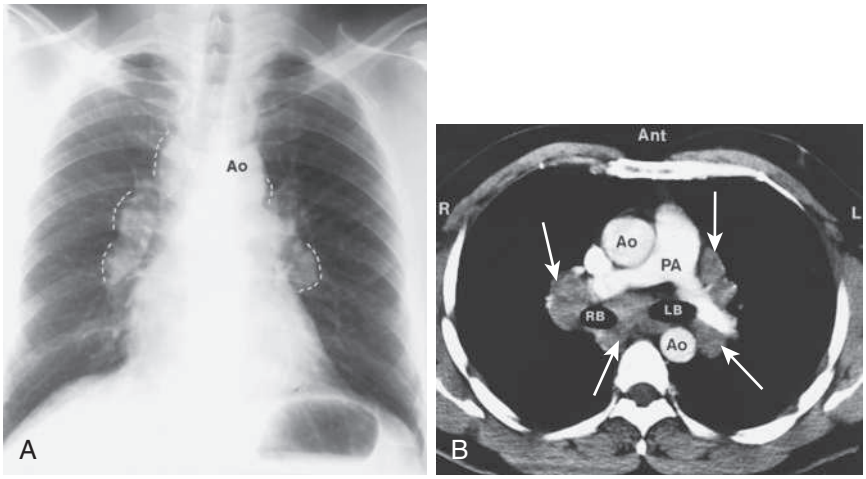

FIG. 3 Sarcoid. Marked lymphadenopathy *(dotted lines)* is seen in the region of both hila in the right paratracheal region **(A).** The transverse contrast-enhanced CT scan of the upper chest **(B)** clearly shows the ascending and descending aorta *(Ao)* as well as the pulmonary artery *(PA)* and superior vena cava. The right and left mainstem bronchus area is also seen. The *arrows* indicate the extensive lymphadenopathy. *LB,* Left bronchus; *RB,* right bronchus. (From Mettler FA [ed]: *Primary care radiology*, Philadelphia, 2000, Saunders.)

LABORATORY TESTS

Laboratory abnormalities:

- Hypergammaglobulinemia, anemia, leukopenia may be present
- Liver function test abnormalities are common, e.g., elevated alkaline phosphatase
- Hypercalcemia (11% of patients), hypercalciuria (40% of patients; attributable to increased gastrointestinal absorption, abnormal vitamin D metabolism, and increased calcitriol production by sarcoid granuloma)
- Angiotensin-converting enzyme: Elevated in approximately 75% of patients with untreated sarcoidosis; nonspecific and poor sensitivity; generally not useful as a diagnostic tool or in following the course of the disease
- Serum adenosine deaminase (ADA); serum amyloid A (SAA) elevated but nonspecific

IMAGING STUDIES

- Chest radiograph (Fig. 3): Pulmonary sarcoidosis is classified based on radiographic pattern. Adenopathy of the hilar and paratracheal nodes is a frequent finding. Parenchymal changes may also be present, depending on the stage of the disease (stage 0, normal radiograph; stage I, bilateral hilar adenopathy; stage II, stage I plus pulmonary infiltrate; stage III, pulmonary infiltrate without adenopathy; stage IV, advanced fibrosis with evidence of "honeycombing," hilar retraction, bullae, cysts, and emphysema).
- Pulmonary function tests (spirometry and diffusing capacity of the lung for carbon dioxide): May be normal or may reveal a restrictive ventilatory defect with reduced forced vital capacity, reduced DLCO, or both. Endobronchial sarcoidosis may exhibit obstructive physiology, depending on severity.
- For patients without apparent lung involvement, ^{18}F-fluorodeoxyglucose positron emission tomography (FDG-PET) is useful in identifying sites for diagnostic biopsy.
- CT imaging, more specifically high-resolution CT, may help detect early parenchymal abnormalities. It is indicated when the chest radiograph is atypical for sarcoidosis.
- FDG-PET and MRI with gadolinium are useful in patients with suspected cardiac and neurologic involvement.
- Gallium-67 scan: Represents an older testing modality. It will localize in areas of granulomatous infiltrates; however, it is not specific and not necessary. The "panda" sign (localization in the lacrimal and salivary glands, giving a "panda" appearance to the face) is suggestive of sarcoidosis.
- Bronchoscopy: Flexible bronchoscopy and bronchoalveolar lavage (BAL) with transbronchial biopsy (showing noncaseating granulomas) are traditional methods for the minimally invasive diagnosis of sarcoidosis. With hilar adenopathy, endobronchial ultrasound (EBUS) is the preferred method for lymph node sampling. BAL may show predominantly lymphocytosis, elevated ADA levels, and elevated CD4:CD8 ratio (4:1).
- Mediastinoscopy: Rarely used nowadays for lymph node sampling and diagnosis.

Rx TREATMENT

ACUTE GENERAL Rx

- Many patients with sarcoidosis will not require any treatment. In general, treatment should be instituted when organ function is threatened. Corticosteroids (Table 1) are the mainstay of therapy when treatment is required (e.g., prednisone 40 mg qd for 8 to 12 wk with gradual tapering of the dose to 10 mg qod over 8 to 12 mo); corticosteroids should be considered in patients with severe symptoms (e.g., dyspnea, chest pain); hypercalcemia; ocular, central nervous system, or cardiac involvement; or progressive pulmonary disease. Patients with interstitial lung disease benefit from oral steroid therapy for 6 to 24 mo.
- A lack of benefit from steroid therapy may be due to the presence of irreversible fibrotic disease. Patients with progressive disease refractory to corticosteroids may be treated with methotrexate 7.5 to 15 mg once per

TABLE 1 Indications for Use of Corticosteroids in Sarcoidosis

Disorder	Treatment
Iridocyclitis	Corticosteroid eye drops; local subconjunctival deposit of cortisone
Posterior uveitis	Oral prednisone
Pulmonary involvement	Steroids rarely recommended for stage I; typically used if infiltrate remains static or worsens over 3-mo period or the patient is symptomatic
Upper airway obstruction	Rare indication for intravenous steroids
Lupus pernio	Oral prednisone shrinks the disfiguring lesions
Hypercalcemia	Responds well to corticosteroids
Cardiac involvement	Corticosteroids usually recommended if patient has arrhythmias or conduction disturbances
Central nervous system involvement	Response is best in patients with acute symptoms
Lacrimal/salivary gland involvement	Corticosteroids recommended for disordered function, not gland swelling
Bone cysts	Corticosteroids recommended if symptomatic

From Andreoli TE [ed]: *Cecil essentials of medicine*, ed 8, Philadelphia, 2010, Saunders.

week or another immunosuppressant such as azathioprine or mycophenolate mofetil.
- Methotrexate, at a dose of 7.5 to 10 mg per week, has been demonstrated to be relatively safe and can also be used as a steroid-sparing agent. Additional agents that have been used with limited clinical experience include pentoxifylline, infliximab, cyclosporine, minocycline, and leflunomide.
- Immunomodulators: Etanercept has not been found to be useful in sarcoidosis. Infliximab has been used with some benefits in cutaneous, pulmonary, and neurologic disease.
- NSAIDs are useful for musculoskeletal symptoms and erythema nodosum.
- Pulmonary rehabilitation in patients with significant respiratory insufficiency. Consider liver and lung transplantation in patients unresponsive to conventional treatment.
- Pulmonary hypertension is a dreaded complication of advanced pulmonary sarcoidosis. The prognosis for patients with sarcoidosis-associated pulmonary hypertension is not known.

DISPOSITION

- The majority of patients with sarcoidosis have spontaneous remission within 2 yr and do not require treatment. Their course can be followed by periodic clinical evaluation, chest radiographs, and pulmonary function tests.
- Blacks have increased rates of pulmonary involvement, a worse long-term prognosis, and more frequent relapses.
- Up to one third of patients have unrelenting disease, leading to clinically significant organ impairment. Adverse prognostic factors in sarcoidosis include age of onset >40 yr, cardiac involvement, neurosarcoidosis, progressive pulmonary fibrosis, chronic hypercalcemia, chronic uveitis, involvement of nasal mucosa, nephrocalcinosis, and presence of cystic bone lesions and lupus pernio.
- Prognosis for Loeffler syndrome is good with remittance within 16 wk in most patients. Symptoms can generally be controlled with NSAIDs. Low-dose glucocorticoids, hydroxychloroquine, and colchicine are also effective.

REFERRAL

Ophthalmologic examination is indicated in all patients with suspected sarcoidosis because ocular findings (iridocyclitis, uveitis, conjunctivitis, and keratopathy) are found in ≥25% of documented cases.

PEARLS & CONSIDERATIONS

COMMENTS

- Serial spirometry and measurement of DLCO can be useful in following response to therapy and disease progression.
- Approximately 15% to 20% of patients with lung involvement advance to irreversible lung impairment (bronchiectasis, cavitation, progressive fibrosis, pneumothorax, and respiratory failure). Death from pulmonary failure occurs in 5% to 7% of patients with sarcoidosis.
- Newer treatment approaches are aimed at targeting mechanisms involving CD4 type 1 helper T cells.
- The diagnosis of sarcoidosis should be reconsidered in the presence of atypical manifestations or persistent/progressive disease despite appropriate therapy.
- Diagnostic biopsy may not be necessary in most patients presenting with asymptomatic bilateral lymphadenopathy (with no other evidence of malignancy), in those with Lofgren syndrome, or in those with Heerfordt syndrome.

BASIC INFORMATION

DEFINITION

Sarcomas are heterogenous groups of malignant cancers of connective tissue, with a wide range of differentiation—blood vessels (angiosarcoma), fat tissue (liposarcoma), and bone (osteosarcoma), among others. Sarcomas can be classified into two basic types: Soft tissue sarcoma (STS) (Table E1) and primary bone sarcoma. Affecting virtually all tissues, they are more common in soft tissues, but 75% occur in the limbs.

ICD-10CM CODES

C22.3	Angiosarcoma of liver
C40	Malignant neoplasm of bone and articular cartilage of limbs
C41	Malignant neoplasm of bone and articular cartilage of other unspecified sites
C49.0	Malignant neoplasm of connective and soft tissue of head, face, and neck
C49.9	Malignant neoplasm of connective and soft tissue, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Sarcoma of bone: Eight cases per million per annum.
  1. In the U.S. there are approximately 2600 new cases annually, and these represent 0.2% of newly diagnosed cancers.
  2. Osteosarcoma (Fig. E1) and Ewing sarcoma occur predominantly during childhood and adolescence.
- STS: 30 cases per million per annum.
  1. In the U.S. there are approximately 11,000 new cases annually, and these represent <1% of newly diagnosed cancers.
  2. The incidence increases with age, with the median age of diagnosis 57 yr.
  3. Men and women are affected equally.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Bone sarcomas. Clinical presentation usually includes:
  1. Pain—at rest or at night
  2. Swelling or mass at the site
  3. Pathologic fractures
- Soft tissue sarcomas:
  1. Present with painless mass (usually >5 cm)
  2. Mass grows slowly for months or years

ETIOLOGY

- Most sarcomas arise sporadically.
- Genetic predispositions:
  1. Familial retinoblastoma (mutation of the RBI gene at 13q14) predisposes to osteosarcoma.
  2. Neurofibromatosis type 1 (mutation of NF1 gene at 17q11) predisposes to malignant peripheral nerve sheath tumor (malignant schwannomas and neurofibrosarcomas).
  3. Diaphyseal aclasis (an autosomal inherited condition) is associated with increased risk of peripheral chondrosarcoma.
  4. Germline mutations associated with soft tissue sarcoma are summarized in Table E2.
- Environmental causes:
  1. Previous radiotherapy for solid tumors predisposes to sarcoma 4 to 10 yr after exposure.
  2. Chronic lymphedema: Associated with the development of angiosarcoma.
  3. Exposure to chemicals (e.g., dioxins, phenoxyacetic herbicides, vinyl chloride increase the risk of hepatic angiosarcoma).
  4. Viruses (e.g., human herpesvirus 8 plays a role in the development of Kaposi sarcoma).
  5. Foreign body (shrapnel, medical implants).
  6. Predisposing environmental factors for soft tissue sarcomas are summarized in Table E3.

DIAGNOSIS

WORKUP

- Soft tissue sarcoma: Any unexplained superficial soft tissue mass >5 cm, or any deep-seated soft tissue mass should be regarded as malignant until proven otherwise.
- Bone sarcoma: Patients with unexplained bone pain, persistent bone tenderness, or nonmechanical bone pain (especially when it disturbs sleep or rest) have bone cancer until proven otherwise.
- Patients with suspected spontaneous fracture or recurrence of the fracture with minor trauma should be considered as having bone cancer.

TABLE E1 Histologic Classification of Soft Tissue Sarcoma

Adipocytic Sarcomas
Atypical lipomatous tumor/well-differentiated liposarcoma
Dedifferentiated liposarcoma
Myxoid liposarcoma
Pleomorphic liposarcoma

Fibroblastic and Myofibroblastic Sarcomas
Malignant solitary fibrous tumor
Inflammatory myofibroblastic tumor
Myxoinflammatory fibroblastic sarcoma
Infantile fibrosarcomas
Adult fibrosarcomas
Myxofibrosarcoma (myxoid undifferentiated pleomorphic sarcoma)
Low-grade fibromyxoid sarcoma (Evans tumor)
Sclerosing epithelioid fibrosarcoma

So-called Fibrohistiocytic Sarcomas
Undifferentiated pleomorphic sarcoma (UPS)

Smooth Muscle Sarcomas
Leiomyosarcoma

Skeletal Muscle Sarcomas
Embryonal rhabdomyosarcoma
Alveolar rhabdomyosarcoma
Pleomorphic rhabdomyosarcoma

Vascular Sarcomas
Epithelioid hemangioendothelioma
Angiosarcoma
Kaposi sarcoma
Solitary fibrous tumor (formerly hemangiopericytoma)

Osseous Sarcomas
Extraskeletal osteosarcoma

Sarcomas of Uncertain Differentiation
Synovial sarcoma
Epithelioid sarcoma
Alveolar soft part sarcoma
Clear cell sarcoma of soft tissue
Extraskeletal myxoid chondrosarcoma
Desmoplastic small round cell tumor
Extrarenal rhabdoid tumor
Extraskeletal Ewing sarcoma
Intimal sarcoma

Notochord-derived Tumor Behaving Like Sarcomas
Chordoma

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

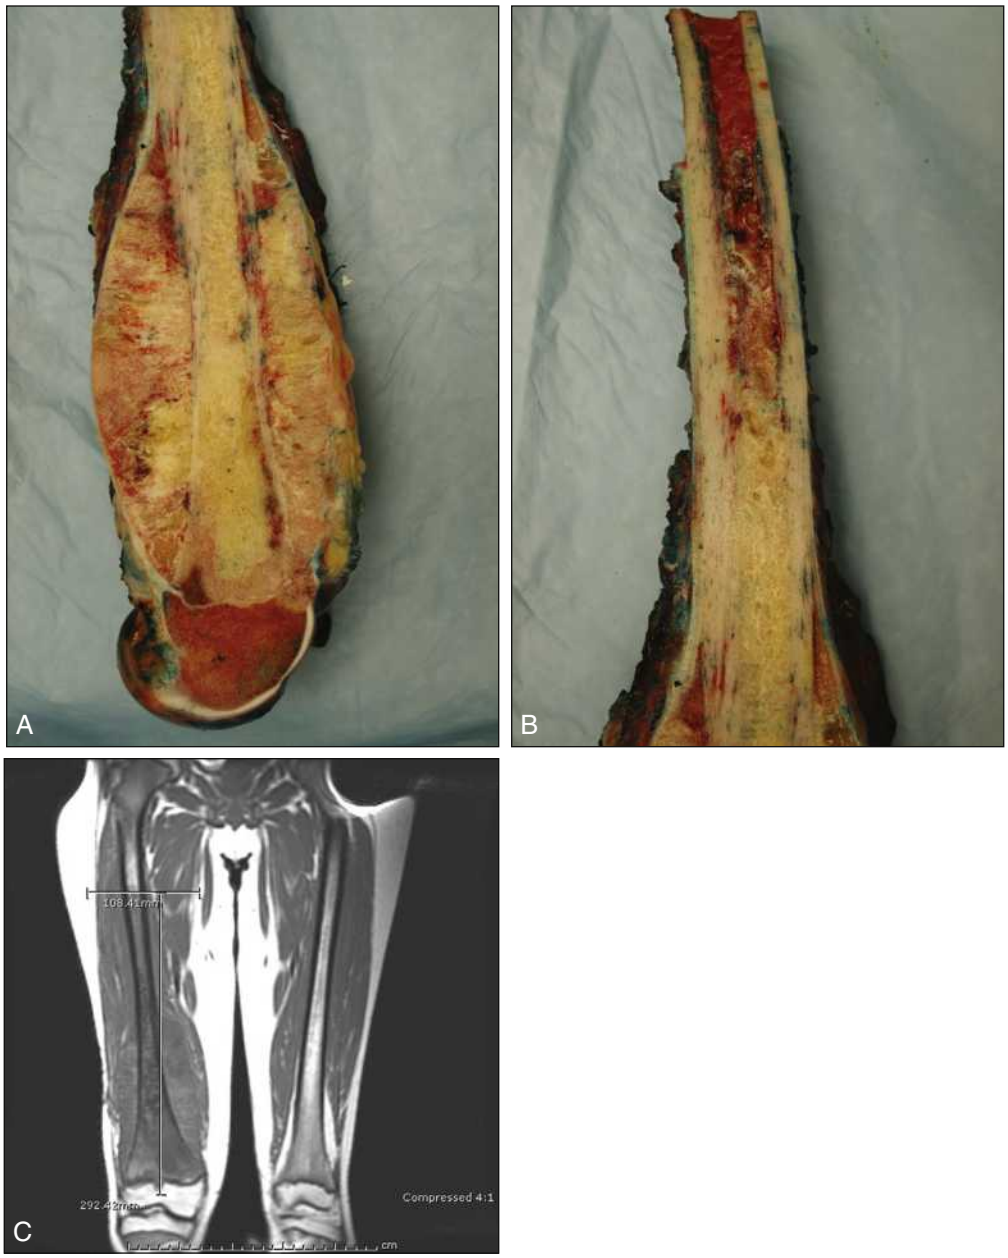

FIG. E1 **A,** Gross photograph of an osteosarcoma of the distal femur. The medullary cavity is filled with tumor, which has replaced the normal marrow contents. The tumor has penetrated and incompletely destroyed the cortex and penetrated the growth plate distally. The Codman triangle, an incomplete host periosteal response, is well demonstrated. Histologically, this would show woven periosteal bone. One also can appreciate how this tumor could enter the joint under the synovium, anteriorly in this case. **B,** A section from higher in the femur shows where the medullary extent of the tumor ends rather abruptly. There is a margin of normal marrow proximal to the marrow extent. **C,** Coronal T1-weighted image of this case nicely shows the extent of the tumor in the medullary cavity and the penetration of the growth plate. It corresponds to the preceding findings seen on the gross specimen. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

- Referral to a sarcoma treatment center of all patients with a suspected sarcoma is recommended.

IMAGING STUDIES (TABLE E4)

- A chest computed tomography (CT) scan (Figs. E2 and E3) is compulsory for staging purposes. Chest spiral CT helps detect lung metastases because hematogenous dissemination to the lungs is the principal form of spread.
- The American Joint Committee on Cancer (AJCC) and International Union Against Cancer (IUCC) are widely used for staging classification.
- Soft tissue sarcoma:
  1. Magnetic resonance imaging (MRI) is the initial imaging modality of choice, especially for soft tissue sarcoma of the extremities, trunk, and head and neck. CT with IV contrast is also useful for diagnosis.
  2. Ultrasound is used to help differentiate between benign and suspicious lesions.
- Bone sarcoma: Radiograph (Fig. E4) is the initial imaging of choice. It helps to rule out bone tumor, shows calcification, and reveals bone erosions. Fig. E5 summarizes radiographic features that may help differentiate benign from malignant lesions. Diagnostic workup for bone sarcomas is summarized in Table E5.
- A multidisciplinary team approach is essential and should include a radiologist, surgeon, pathologist, medical oncologist, and radiation oncologist.

BIOPSY

- In nearly all cases a biopsy is needed to establish a tissue diagnosis. Guidelines for biopsy are summarized in Box E1.
- Multiple core needle biopsies are usually done.
- An excisional biopsy may be used for superficial lesions <5 cm.

TABLE E2 Germline Mutations Associated with Soft Tissue Sarcoma

Syndrome	Inheritance Pattern	Locus	Gene	Associated Soft Tissue Sarcomas
Familial gastrointestinal stromal tumor syndrome	AD	4q12	*KIT*	Gastrointestinal stromal tumor
Familial desmoid fibromatosis (Gardner syndrome)	AD	5q21	*APC*	Desmoid fibromatosis
Li-Fraumeni syndrome	AD	17p13,22q11	*TP53, CHK2*	Multiple types
Neurofibromatosis type I (von Recklinghausen disease)	AD	17q11	*NF1*	Malignant peripheral nerve sheath tumors
Retinoblastoma	AD	13q14	*RB1*	Multiple types
Rhabdoid predisposition syndrome	AD	22q11	*SNF5/INII*	Malignant rhabdoid tumors
Werner syndrome	AR	8p11–12	*WRN*	Multiple types

AD, Autosomal dominant; *AR,* autosomal recessive.
From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

TABLE E3 Soft Tissue Sarcoma: Predisposing Environmental Factors

Factor	Agent	Patient Population	Comment
Radiotherapy	Orthovoltage and megavoltage radiation	Therapeutic radiation patients	Most commonly undifferentiated pleomorphic sarcoma and osteosarcoma; dose-response relationship
Chemotherapy	Alkylating agents: Cyclophosphamide, melphalan, procarbazine, nitrosourea, and chlorambucil	Pediatric cancer patients	Relative risk of bone sarcoma increased with cumulative drug exposure
Chemical exposure	Phenoxyacetic acids: 2,4-dichlorophenoxyacetic acid (2,4-D); 2,4,5 trichlorophenoxyacetic acid (2,4,5-T); 2 methyl-4 chlorophenoxyacetic acid (MCPA)	Forestry and agricultural workers	Phenoxy herbicide and defoliant exposure
	2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD); dioxin	Vietnam veterans	No clear link demonstrable for dioxin (Agent Orange)
	Chlorophenols	Sawmill workers	
	Thorotrast	Diagnostic x-ray patients	Hepatic angiosarcoma
	Vinyl chloride	Vinyl chloride workers	Hepatic angiosarcoma
	Arsenic	Vineyard workers	Hepatic angiosarcoma after exposure to arsenical herbicides
Chronic lymphedema		Postsurgery patients Postradiation patients Patients with congenital lymphedema or filariasis	Stewart-Treves syndrome (lymphangiosarcoma)

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

TABLE E4 Radiographic Techniques Available

1. Plain films: Loss of trabeculation, matrix identification, calcification, etc.
2. Bone scan: Whole body, three phases to evaluate vascularity, static skeletal survey to evaluate for skeletal metastatic disease
3. MRI (magnetic resonance imaging): Excellent soft tissue contrast, sometimes nearly diagnostic; T1 best for anatomy, contrast enhancement, magnetic resonance angiography capability, best overall single study when properly monitored by a physician
4. CT (computed tomography): Margination, matrix identification, calcification, cortical disruption, axial localization of lesion; imaging for pulmonary metastatic disease
5. Rapid whole-body short tau inversion recovery (STIR) MRI: Excellent survey study with cooperative patients and in institutions using these techniques
6. PET (positron emission tomography): Adds metabolic parameter used to monitor effectiveness of neoadjuvant chemotherapy; staging in Ewing sarcoma

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

- In carefully selected cases an open biopsy may be done (rarely used because of its high complication rate).
- For difficult to palpate or necrotic soft sarcomas, ultrasound or CT–guided biopsies are performed.
- Biopsy results are interpreted collaboratively by the specialist sarcoma pathologist, surgeon, and radiologist together.

HISTOLOGIC DIAGNOSIS

- Treatment planning is guided by a histologic diagnosis.
- Histologic diagnosis is made according to the World Health Organization (WHO) classification.
- WHO has defined >50 histologic subtypes of soft tissue sarcoma.
- Newer methods such as immunocytochemistry and cytogenetics can aid diagnosis by identifying tumor lineage.
- Sarcomas with complex karyotypes are summarized in Table E6.

Rx TREATMENT

Treatment depends on the extent of the disease and falls into several groups.

ACUTE GENERAL Rx

- Surgical resection: Most cases are treated by surgery. For example, in most adults soft tissue sarcoma and sarcoma of bone are not very sensitive to chemotherapy. Fig. E6 illustrates a management strategy for soft tissue sarcomas.
  1. Surgery must be done by surgeon trained to treat this disease.
  2. Wide excision with negative margins is the standard surgical procedure.
  3. For bone sarcomas amputation has been the standard procedure. Recent advances

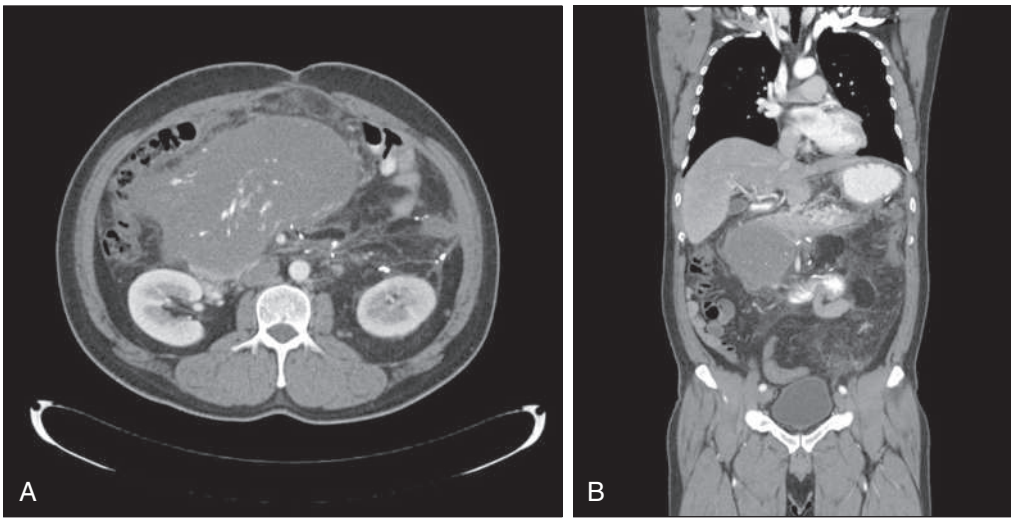

FIG. E2 A, A 48-yr-old man with retroperitoneal and intraabdominal well-differentiated and dedifferentiated liposarcoma. Axial contrast-enhanced computed tomography (CT) images show a large, heterogeneous mass with foci of calcification, consistent with osteosarcoma divergent differentiation sometimes seen with this form of sarcoma. In this situation, the finding of osteoblasts does not merit the use of chemotherapy for osteosarcoma; the risk of tumor recurrence rests entirely with the dedifferentiated liposarcoma portion of the diagnosis. **B,** The same patient as in **A,** with coronal sectioning from data existing from the axial CT scans. This technique is commonly used with both magnetic resonance imaging and CT. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

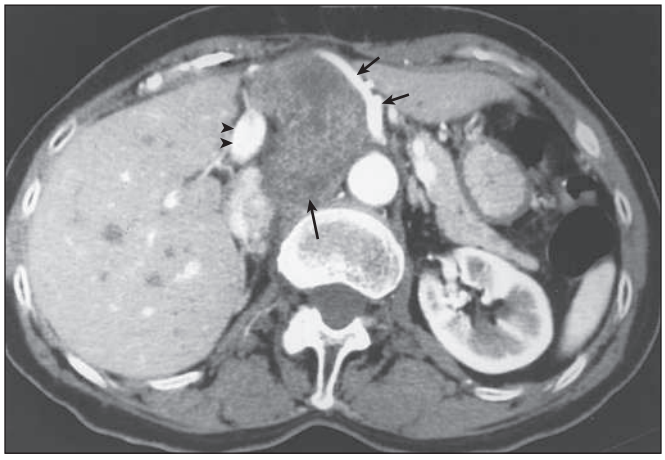

FIG. E3 Contrast-enhanced computed tomography scan of the abdomen demonstrating a retroperitoneal undifferentiated pleomorphic sarcoma. Note the large mass *(bottom arrow)* between the aorta and inferior vena cava with abutment and displacement of celiac axis and hepatic artery *(top arrows).* The portal vein *(arrowheads)* is well visualized, and low-attenuation foci in the liver, which are unopacified hepatic veins, are incidentally visualized. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

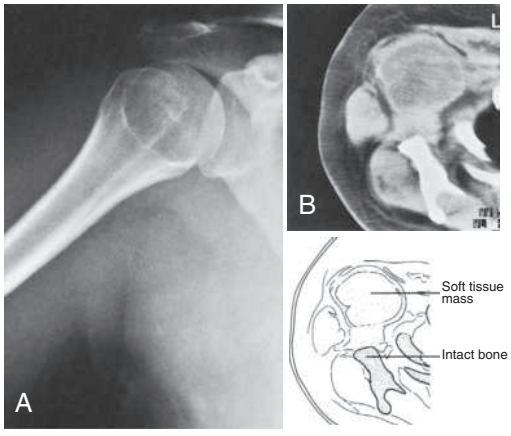

FIG. E4 Fibrosarcoma. A, Anteroposterior plain film of the shoulder of a 40-yr-old woman with a history of an enlarging mass in the right axilla shows an ill-defined mass adjacent to the lateral border of the scapula. **B,** CT section with contrast enhancement shows the extent of the mass and the lack of bone involvement. The tumor proved to be a fibrosarcoma. (From Skarin AT: *Atlas of diagnostic oncology,* ed 3, St Louis, 2003, Mosby.)

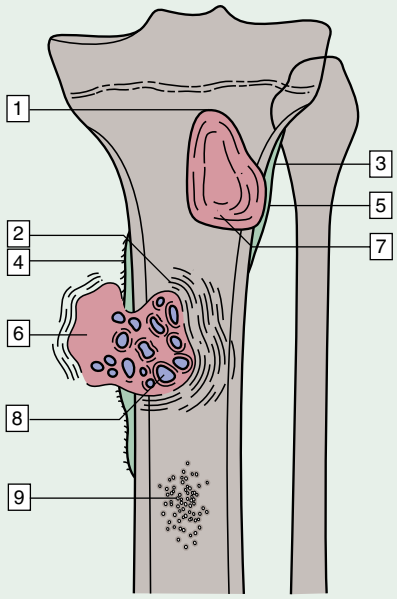

Feature	Benign (slow-growing process)	Malignant (aggressive process)
Border	1. Sharply outlined, sclerotic (narrow zone of transition)	2. Poorly defined (wide zone of transition)
Periosteal reaction	3. Solid, uninterrupted	4. Interrupted (sunburst, Codman triangle)
Soft tissue extension/mass	5. Absent or contained by shell of periosteal new bone	6. Frank extension through destroyed periosteum
Type of bone destruction	7. Geographic: Uniformly destroyed area with sharply defined border	8. "Moth-eaten" (likely malignant): Destroyed areas with ragged borders
		9. Permeative (aggressive/malignant): Ill-defined destruction spreading through marrow space

FIG. E5 Benign versus malignant bone lesions. The radiographic features illustrated may help differentiate benign from malignant lesions. (From Bullough PG, Vigorita VJ: *Atlas of orthopedic pathology,* Baltimore/New York, 1984, University Park Press/Gower Medical Publishing; in Skarin AT: *Atlas of diagnostic oncology,* 4 ed, St Louis, 2010, Mosby.)

TABLE E5 Diagnostic Workup Algorithm for Bone Sarcomas

1. Anteroposterior and lateral radiographs of the bone/joint involved
2. If a malignant bone lesion is suspected, proceed to:
   - Magnetic resonance imaging (MRI) of the lesion and coronal T1 images of the entire bone
   - Chest computed tomography (CT) to screen for pulmonary metastases
   - Radionuclide bone scan to look for "skip" and other bony metastases
3. Review with multidisciplinary team (surgeon, oncologist, radiotherapist, radiologist, and pathologist); decide whether tissue will be needed for cytogenetics or other special biologic studies
4. Plan open or needle biopsy by surgeon or interventional radiologist (after reviewing images with the radiologist who will perform the biopsy)

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

BOX E1 Guidelines for Biopsy

Needle Biopsy

1. Planning: Biopsy tract must be in line of potential resection.
2. Traverse only one compartment and only one muscle if possible.
3. Avoid contamination of joint.
4. Microbiologic culture.
5. Prolonged gentle pressure for hemostasis.

Incisional Biopsy

1. Planning: Plan most appropriate biopsy tract and avoid transverse incisions.
2. Use pneumatic tourniquet after gravity exsanguination.
3. Avoid contamination of joint.
4. Avoid exposure of neurovascular structures.
5. Monitor biopsy with frozen sections.
6. Microbiologic culture if there is question.
7. Maintain integrity of deep tumor-host margin; could extend necessary surgical margin.
8. Absolute hemostasis; thrombogenic agents (e.g., thrombin, Oxycel, Avitene).
9. Hemostatic closure of pseudocapsule.
10. Subcuticular closure.

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

TABLE E6 Sarcomas with Complex Karyotypes

Type of Sarcoma	Resembles
Fibrosarcoma (other than congenital)	Fibrous tissue
Leiomyosarcoma	Smooth muscle
Undifferentiated pleomorphic sarcoma	Poorly differentiated
Osteosarcoma	Bone
Chondrosarcoma (types other than extraskeletal myxoid)	Cartilage
Liposarcoma (types other than myxoid)	Fat
Embryonal rhabdomyosarcoma	Skeletal muscle
Malignant peripheral nerve sheath tumor*	Nerve sheath
Angiosarcoma	Endothelium

*Some have NF1 mutations.
From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

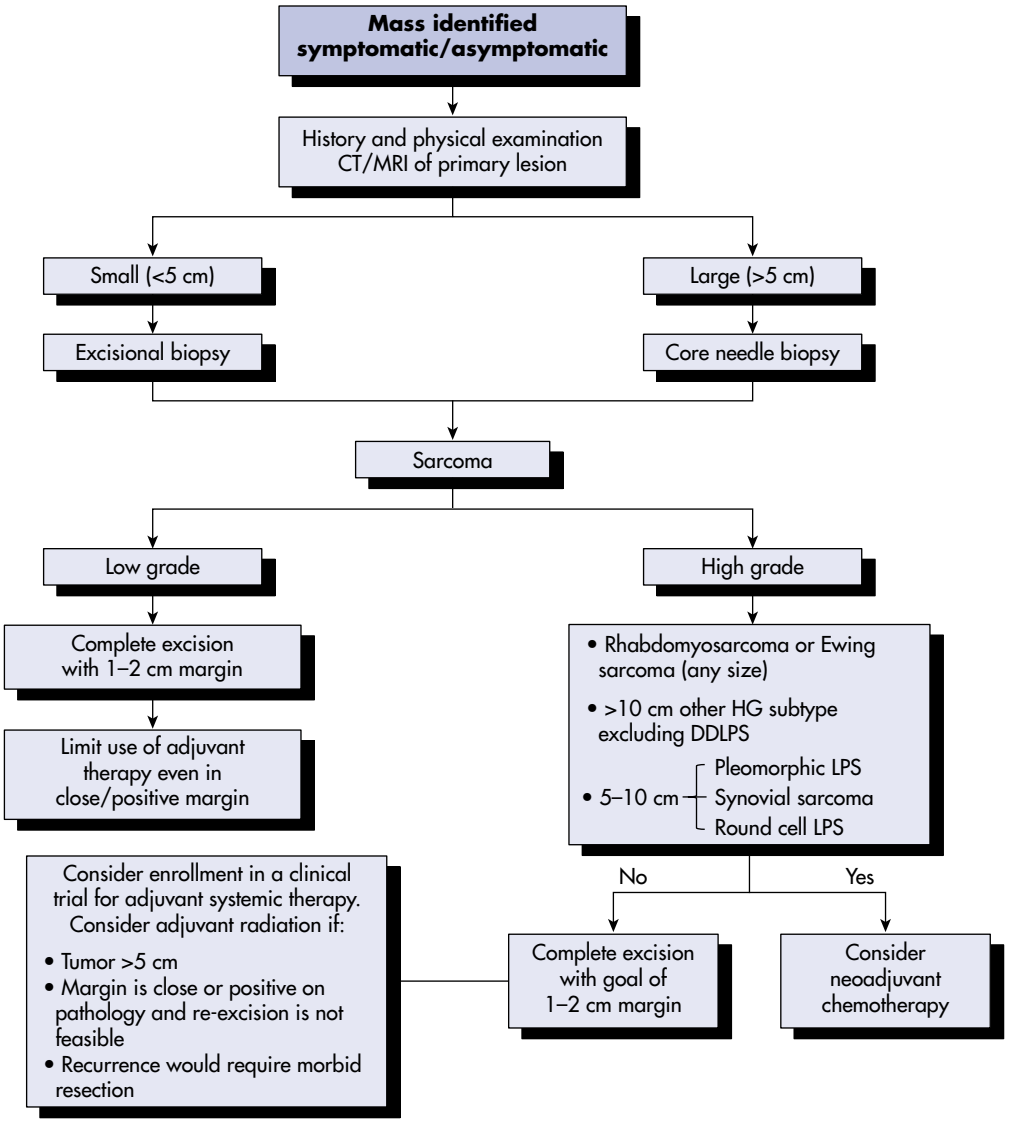

FIG. E6 Management strategy for soft tissue sarcoma. *CT*, Computed tomography; *DDLPS*, dedifferentiated liposarcoma; *HG*, high-grade; *LPS*, liposarcoma; *MRI*, magnetic resonance imaging. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

permit the avoidance of amputation with limb-sparing surgery followed by reconstruction by endoprosthetic replacement.

- Radiotherapy is used often in adjuvant fashion after primary sarcoma resection as a means to decrease local recurrences, e.g., in extremity or retroperitoneal sarcomas.
- Chemotherapy is typically used followed by surgery in cases of advanced sarcoma or palliatively in case of metastatic disease.
  1. Upfront chemotherapy is used to reduce disseminated micrometastases and to reduce tumor size preoperatively. Recent data support use of chemotherapy combined with hyperthermia in selected soft tissue sarcomas of the extremities before resection.
  2. Systemic chemotherapy regimens for advanced STS typically comprise multiple drugs such as the MAID regimen (mesna, doxorubicin, ifosfamide, dacarbazine) and the AIM regimen (doxorubicin, ifosfamide, mesna). Single-agent therapy with either doxorubicin or ifosfamide is also appropriate in the palliative setting.
  3. More recently, pazopanib, a tyrosine kinase inhibitor, has been approved for patients with metastatic or recurrent sarcoma. Trabectedin (an agent derived from a marine sponge) and eribulin (a microtubule inhibitor) have now been approved in advanced leiomyosarcoma or liposarcoma after showing an overall survival benefit.
  4. Olaratumab, a monoclonal antibody directed against platelet-derived growth factor (PDGF), had been approved based on early survival data when used in combination with doxorubicin as a first-line option in metastatic soft tissue sarcomas, but the mature survival results did not confirm a survival benefit.
- Follow-up of bone sarcoma after treatment includes:
  1. Periodic monitoring with radiographs and other imaging modalities.
  2. CT scan of the chest.
  3. Bone scan.
- Follow-up of soft tissue sarcoma (extremities):
  1. Physical exam detects 97% of recurrence.
  2. Physical exam is done every 3 to 6 mo for 3 yr, then every 6 mo for the next 2 yr for stage II and III cancers, then annually.
  3. Imaging.
- Stage I: CXR every 6 to 12 mo.
- Stages II and III: Image the primary site with MRI or CT.
- Chest x-ray or chest CT every 3 to 6 mo for 5 yr, then annually.

REFERRAL

- Sarcomas are relatively uncommon yet comprise a wide variety of different entities; as such, evaluation by multidisciplinary oncology teams with expertise in this field is recommended.
- Treatment and follow-up guidelines have been published by the National Comprehensive Cancer Network (www.nccn.org).

BASIC INFORMATION

DEFINITION

Scabies is a contagious disease caused by the mite *Sarcoptes scabiei.*

ICD-10CM CODE
B86 Scabies

EPIDEMIOLOGY & DEMOGRAPHICS

- Scabies is generally acquired by sleeping with or in the bedding of infested individuals.
- It is generally associated with poor living conditions and is also common in hospitals and nursing homes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Primary lesions are caused when the female mite burrows within the stratum corneum, laying eggs within the tract she leaves behind; burrows (linear or serpiginous tracts, see Fig. E1) end with a minute papule or vesicle.
- Primary lesions (Fig. E2) are most commonly found in the web spaces of the hands, wrists, buttocks, scrotum, penis, breasts, axillae, and knees. They are often confused with eczema (Fig. E3).
- Secondary lesions result from scratching or infection.
- Intense pruritus, especially nocturnal, is common; it is caused by an acquired sensitivity to the mite or fecal pellets and is usually noted 1 to 4 wk after the primary infestation.
- Examination of the skin may reveal burrows, tiny vesicles, excoriations, inflammatory papules.
- Widespread and crusted lesions (Norwegian or crusted scabies) may be seen in elderly and immunocompromised patients (Fig. E4). Pruritus may be mild or absent due to impaired host immune response.
- Table 1 summarizes the different presenting forms of scabies.

ETIOLOGY

- Human scabies is caused by the mite *S. scabiei,* var. *hominis* (Fig. 5). After impregnation on the skin surface, the gravid female burrows in the stratum corneum within 30 min and gradually extends the tract along the boundary with the stratum granulosum depositing 10 to 25 oval eggs in a 4- to 5-wk period. The eggs hatch in 3 to 5 days, and larvae move to the skin surface and mature in 2 to 3 wk, resuming the cycle.
- Clinical manifestations result from a delayed type IV hypersensitivity reaction to the mite, eggs, saliva, or scybala.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pediculosis
- Atopic dermatitis
- Flea bites
- Seborrheic dermatitis
- Dermatitis herpetiformis
- Contact dermatitis
- Nummular eczema
- Syphilis
- Other insect infestation

WORKUP

Diagnosis is made on the clinical presentation and on the demonstration of mites, eggs, or mite feces.

LABORATORY TESTS

- Microscopic demonstration of the organism, feces, or eggs: A drop of mineral oil may be placed over the suspected lesion before removal (Box 1); the scrapings are transferred directly to a glass slide; a drop of potassium hydroxide is added and a cover slip is applied.
- Skin biopsy is rarely necessary to make the diagnosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Clothing, underwear, and towels used in the 48 hours before treatment must be laundered.

ACUTE GENERAL Rx

- Permethrin 5% cream is usually effective with one treatment; it should be massaged into the skin from head to soles of feet and applied under fingernails and toenails (it is best if applied in the evening and left overnight to maximize exposure); remove 8 to 14 hr later by washing. Repeat in 1 to 2 wk. Permethrin is safe for children >2 mo old.
- A single dose (150 to 200 μg/kg in 6-mg tablets) of ivermectin, an antihelmintic agent, is also effective for the treatment of scabies. It is the best treatment for generalized crusted scabies. Three to seven doses of ivermectin given on days 1, 2, 8, 9, 15, 22, and 28 may be needed for crusted scabies.
- Pruritus generally abates 24 to 48 hr after treatment but can last up to 2 wk; oral antihistamines are effective in decreasing postscabietic pruritus.
- Topical corticosteroid creams may hasten the resolution of secondary eczematous dermatitis.
- If the patient is a resident of an extended care facility, it is important to educate the patients, staff, family, and frequent visitors about scabies and the need to have full cooperation in treatment. Scabicide should be applied to all

TABLE 1 Different Presenting Forms of Scabies

Presenting Forms of Scabies	Specific High-Risk Populations	Clinical Manifestations	Limited Differential Diagnoses
Classic scabies (scabies vulgaris)	Infants and children; sexually active adults; men who have sex with men	Intense generalized pruritus, worse at night; inflammatory pruritic papules localized to finger webs, flexor aspects of wrists, elbows, axillae, buttocks, genitalia, female breasts; lesions and pruritus spare the face, head, and neck; secondary lesions include eczematization, excoriation, impetigo	Dermatitis herpetiformis, drug reactions, eczema, pediculosis corporis, lichen planus, pityriasis rosea
Scalp scabies	Infants and children; institutionalized older adults; AIDS patients; patients with preexisting crusted scabies	Atypical crusted papular lesions of the scalp, face, palms, and soles	Dermatomyositis, ringworm, seborrheic dermatitis
Crusted scabies (Norwegian scabies, scabies norvegica, scabies crustosa)	Institutionalized older adults; institutionalized developmentally disabled (Down syndrome); homeless, especially HIV-positive; all immunocompromised patients, particularly those with AIDS or positive for HIV or HTLV-1; transplant recipients; patients on prolonged systemic corticosteroids and chemotherapy	Psoriasiform hyperkeratotic papular lesions of the scalp, face, neck, hands, feet, with extensive nail involvement; eczematization and impetigo common	Contact dermatitis, drug reactions, eczema, erythroderma, ichthyosis, psoriasis
Nodular scabies	Sexually active adults; men who have sex with men; HIV-positive men > HIV-positive women	Violaceous pruritic nodules localized to male genitalia, groin, axillae, representing hypersensitivity reaction to mite antigens	Acropustulosis, atopic dermatitis, Darier disease, lupus erythematosus, lymphomatoid papulosis, papular urticaria, necrotizing vasculitis, secondary syphilis

AIDS, Acquired immunodeficiency syndrome; *HIV*, human immunodeficiency virus; *HTLV-1*, human T-cell lymphotropic virus type 1.
From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

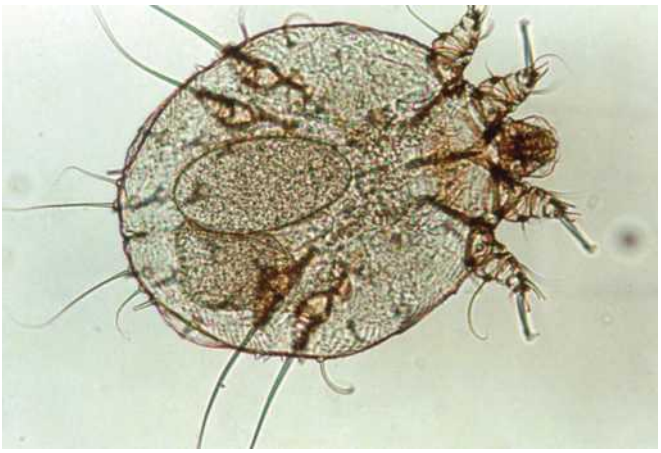

FIG. 5 Scabies mite. Note the eggs within the body of the mite. (Live scabies mite, ×40 magnification.) (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

BOX 1 Performing a Mineral-Oil Examination for Scabies

1. Apply a drop of mineral oil to the lesion(s) to be scraped.
2. Scrape through the lesion with a number 15 scalpel blade (a small amount of bleeding is expected with appropriately deep scrapings).
3. Smear contents of scraping on a clean glass slide.
4. Add a few more drops of mineral oil.
5. Place cover slip over oil and examine under microscope at low power.

Criteria for a positive mineral oil examination:
Scabies mite.
or
Ova (eggs).
or
Scybala (feces).

From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.

patients, staff, and frequent visitors, whether symptomatic or not; symptomatic family members of staff and visitors should also receive treatment.
- Table 2 summarizes currently recommended treatment for scabies.

DISPOSITION

Refractory cases usually are seen with immunocompromised hosts or patients with underlying skin diseases. ***Norwegian scabies*** refers to a highly contagious variant often found in institutions caring for physically and mentally disabled individuals.

PEARLS & CONSIDERATIONS

COMMENTS

- Lindane is potentially neurotoxic and should not be used on infants or pregnant women (permethrin is safe in pregnancy and infants over 2 mo old).
- Sexual partners should be notified and treated.

Scabies (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

TABLE 2 Currently Recommended Treatment for Scabies

Scabicides	FDA Approved?	Pregnancy Category*	Dosing Schedule	Safety Profile	Contraindications
5% Permethrin cream (Actin, Nix, Elimite)	Yes	B	Apply from neck down; wash off after 8-14 hr; good residual activity, but second application recommended after 1 wk	Excellent; itching and stinging on application	Prior allergic reactions; infants <2 mo of age; breastfeeding
1% Lindane lotion or cream	Yes	B	Apply 30-60 ml from neck down; wash off after 8-12 hr; no residual activity; increasing drug resistance	Potential for central nervous system toxicity from organochloride poisoning, usually manifesting as seizures, with overapplication and ingestions	Preexisting seizure disorder; infants and children <6 mo of age; pregnancy; breastfeeding
10% Crotamiton cream or lotion (Eurax)	Yes	C	Apply from neck down on two consecutive nights; wash off 24 hr after second application	Excellent; not very effective; exacerbates pruritus	None
2%-10% Sulfur in petrolatum ointments	No	C	Apply for 2-3 days, then wash	Excellent; not very effective	Preexisting sulfur allergy
10%-25% Benzoyl benzoate lotion	No	None	Two applications for 24 hr with 1-day to 1-wk interval	Irritant; exacerbates pruritus; can induce contact irritant dermatitis and pruritic cutaneous xerosis	Preexisting eczema
0.5% Malathion lotion (Ovide), 1% malathion shampoo (unavailable in the U.S.)	No	B	95% ovicidal; rapid (5 min) killing; good residual activity; increasing drug resistance	Flammable 78% isopropyl alcohol vehicle stings eyes, skin, mucosa; increasing drug resistance; organophosphate poisoning risk with overapplication and ingestions	Infants and children <6 mo of age; pregnancy; breastfeeding
Ivermectin (Stromectol)	Yes	C	200 μg/kg single PO dose, may be repeated in 14-15 days; not ovicidal, second dose on day 14 or 15 highly recommended; recommended for endemic or epidemic scabies in institutions and refugee camps	Excellent; may cause nausea and vomiting; take on empty stomach with water	Safety in pregnancy uncertain; probably safe during breastfeeding; not recommended for children younger than 5 yr of age or weighing <15 kg

FDA, U.S. Food and Drug Administration; *PO*, by mouth.
*U.S. Food and Drug Administration (FDA) safety in pregnancy categories: A, safety established; B, presumed safe; C, uncertain safety; D, unsafe; X, highly unsafe.

Scarlet Fever (PTG)

BASIC INFORMATION

DEFINITION

Scarlet fever is a rash involving the skin and tongue and complicating streptococcal group A pharyngitis.

SYNONYMS

Scarlatina
SF

ICD-10CM CODES

A38	Scarlet fever
A38.0	Scarlet fever with otitis media
A38.1	Scarlet fever with myocarditis
A38.8	Scarlet fever with other complications
A38.9	Scarlet fever, uncomplicated

EPIDEMIOLOGY & DEMOGRAPHICS

- Same as streptococcal pharyngitis; namely, children ages 5 to 15 yr. May also complicate impetigo
- Most common in cooler climates during the late fall, winter, and early spring
- Most cases follow tonsillitis or pharyngitis; however, it has also been reported after wounds ("surgical scarlet fever"), burns, and pelvic or puerperal infections

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Diffuse erythema, beginning on face and spreading to neck, back, chest, rest of trunk, and extremities (Fig. E1, A). Most intense on inner aspects of arms and thighs.
- Erythema blanches, but nonblanching petechiae may be present or produced by a tourniquet.
- Strawberry or raspberry tongue (Fig. E1, B, C).
- Rash lasts approximately 1 wk and then desquamates.
- Febrile illness with headache, malaise, anorexia, and pharyngitis begins after a 2- to 4-day incubation period.
- Scarlatinal rash begins 1 or 2 days after the onset of pharyngitis.

ETIOLOGY

Caused by group A beta-hemolytic *Streptococcus* infection, which produces one of three erythrogenic toxins (NOTE: Some streptococcal species have the ability to cause both scarlet fever and rheumatic fever).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral exanthems (covered in Section II)
- Kawasaki syndrome
- Toxic shock syndrome
- Drug rashes

See "Differential Diagnosis" of "Pharyngitis/Tonsillitis" in Section I.

WORKUP

- Identification of group A *Streptococcus* by throat culture
- Streptolysin O antibody titers

TREATMENT

- Penicillin 250 mg PO qid for 10 days or erythromycin 250 mg PO qid for 10 days in penicillin-allergic patients. A clinical response can be expected in 24 to 48 hr.
- Benzathine penicillin 1 to 2 million U IM once; may be used for a patient who cannot swallow pills.

COMPLICATIONS (RARE)

- Peritonsillar abscess
- Mastoiditis
- Otitis media
- Pneumonia
- Sepsis and distant foci of infection
- Acute rheumatic fever
- Inability to swallow liquids or upper airway obstruction requiring hospitalization

NOTE: Failure to respond to penicillin should raise doubt about the diagnosis because *Streptococcus* may be carried in the pharynx without causing infection.

PEARLS & CONSIDERATIONS

COMMENTS

Patients with antibodies against the toxin are spared the rash but still develop other symptoms of the infection (e.g., sore throat).

BASIC INFORMATION

DEFINITION

Schistosomiasis is caused by infection with parasite blood flukes known as schistosomes. Their life cycle is illustrated in Fig. E1.

SYNONYMS

Bilharziasis
Urinary schistosomiasis
Hepatosplenic schistosomiasis
Swimmer's itch
Katayama fever
Snail fever

ICD-10CM CODES

B65	Schistosomiasis (bilharziasis)
B65.0	Schistosomiasis due to *Schistosoma haematobium*
B65.1	Schistosomiasis due to *Schistosoma mansoni*
B65.2	Schistosomiasis due to *Schistosoma japonicum*
B65.8	Other schistosomiasis
B65.9	Schistosomiasis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Worldwide >230 million people, 20 million people with severe disease, and >200,000 deaths annually. Roughly 85% of cases globally occur in Africa, although incidence may be increasing in southern Europe. U.S. travelers to endemic areas are at risk of infection.
- Geographic distribution of schistosomiasis (see Fig. E2) is confined to an area between 36° north and 34° south latitude, where freshwater temperatures average 25° to 30° C (77° to 86° F), and where freshwater snail (intermediate host) habitats are located.

PREVALENCE: The greatest cercarial exposure usually occurs in boys ages 5 to 10 yr.

DISTRIBUTION:

- *Schistosoma mansoni* in tropical and subtropical areas of sub-Saharan Africa, the Middle East, South America, and the Caribbean
- *S. haematobium* in North Africa, sub-Saharan Africa, the Middle East, and India
- *S. japonicum* in Asia, particularly in China, the Philippines, Thailand, and Indonesia
- *S. intercalatum* in Cameroon and the Democratic Republic of the Congo
- *S. mekongi* in Mekong River (Laos and Cambodia)

ETIOLOGY & PATHOGENESIS

- Human infections are caused by five main schistosome species (three major ones and two less common): *S. mansoni, S. haematobium, S. japonicum, S. mekongi,* and *S. intercalatum.*
- Acquisition of disease occurs via contact with fresh water containing infectious free-living cercarial larvae that penetrate intact skin and transform into schistosomulae.

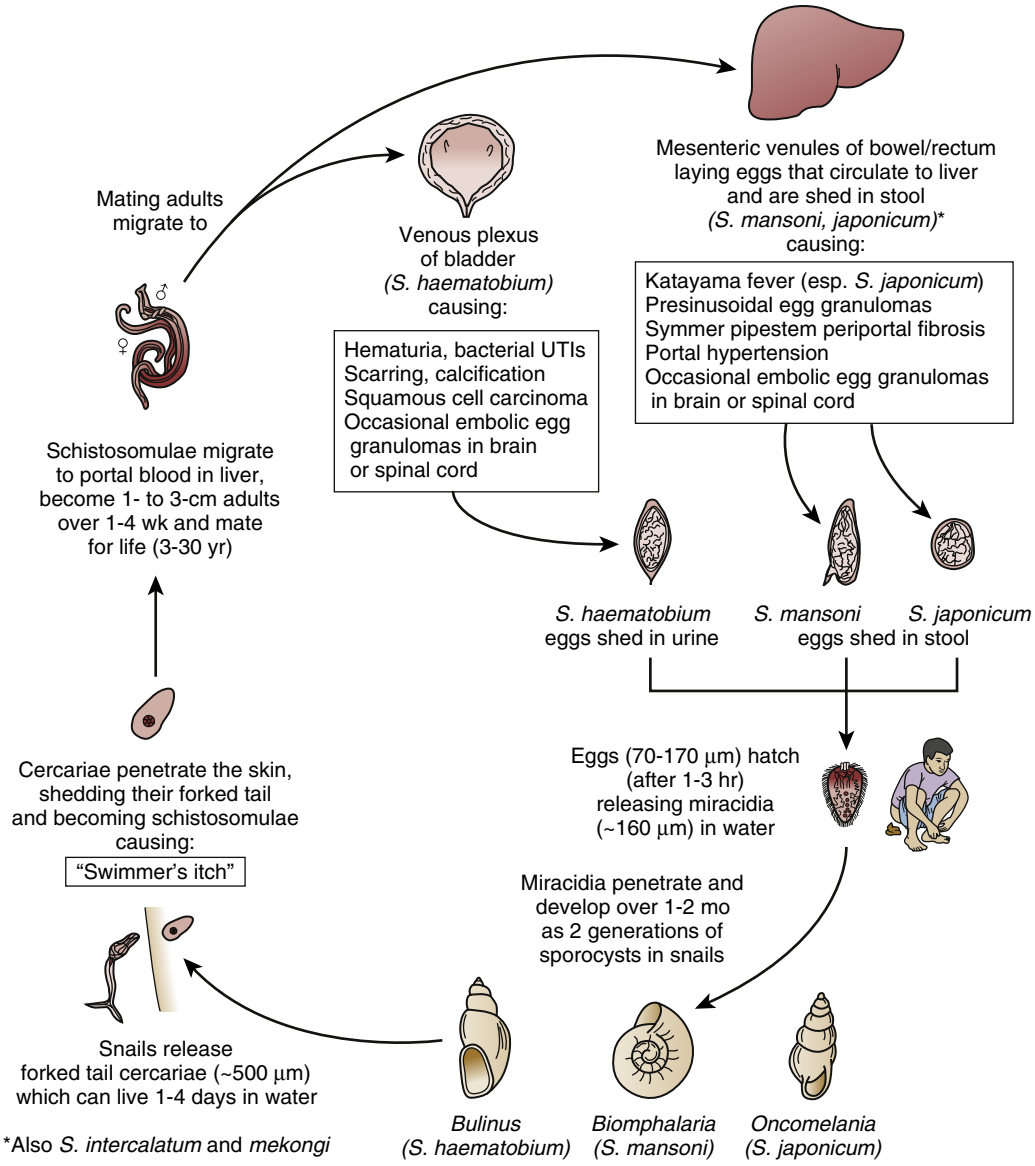

FIG. E1 Life cycle of a schistosome. *UTIs,* Urinary tract infections. (From King CH: Schistosomiasis. In Guerrant RL, et al. [eds]: *Tropical infectious diseases, principles, pathogens, and practice*, ed 2, Philadelphia, 2006, Churchill Livingstone.)

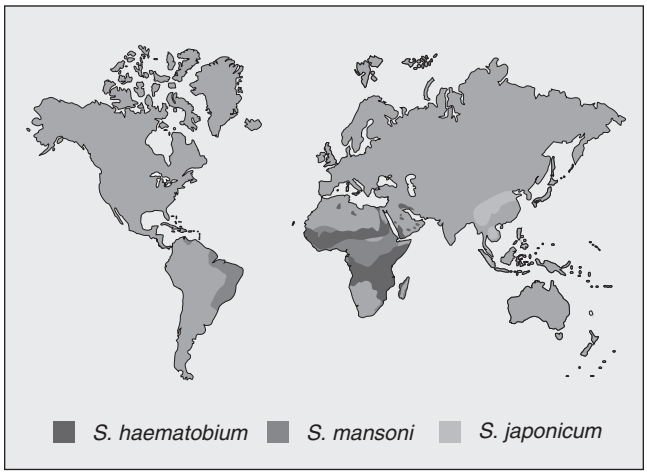

FIG. E2 World map showing the geographic distribution of the main pathogenic schistosomes. (From Floege J, et al.: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.)

- Once inside humans, they ultimately reach, depending on the species, the venules of the target organs and develop into adult worms. Male and female worms mate continuously at this point.
- Adult worms are 1 to 3 cm in length and live 3 to 7 yr. Females lay eggs that on contact with fresh water become miracidium larvae that then enter freshwater snails (an intermediate host). The miracidia develop further and exit the snail in water as cercarial larvae that will enter humans as the definitive host.
- The eggs produced by adult worms are released into the bloodstream and can invade local tissue. This tissue insult induces a granulomatous reaction that involves T-helper-2 cytokines, eosinophils, and macrophages.
- These granulomas contain the egg and the proteolytic enzymes it releases to prevent tissue necrosis. Granuloma formation results in chronic inflammation and disease manifestation in humans.
- In the U.S., most cases are acquired during foreign travel or appear in immigrants.
- Incubation period is typically 2 to 12 wk for acute illness, but chronic infection can remain asymptomatic for years.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

ACUTE SYMPTOMS:
- Swimmer's itch: Initial penetration of the skin by cercariae. Most commonly seen with *S. japonicum* infection.
- Katayama fever: Systemic hypersensitivity reaction to migrating parasites early in infection and lasting 2 to 10 wk.

CHRONIC SYMPTOMS:
- Failure to thrive in children from regions where schistosomiasis is endemic
- Intestinal schistosomiasis:
  1. Abdominal pain
  2. Poor appetite
  3. Bloody diarrhea
  4. Iron-deficiency anemia
  5. Intestinal polyp
  6. Bowel ulcer and strictures
- Hepatic schistosomiasis:
  1. Hepatomegaly
  2. Splenomegaly
  3. Portal hypertension
  4. Esophageal varices and hematemesis
  5. Ascites
- Urinary schistosomiasis:
  1. Hematuria (micro- or macroscopic)
  2. Dysuria
  3. Urinary frequency
  4. Fibrosis of bladder, ureters, and female genital tract
  5. Squamous cell cancer of bladder
  6. Proteinuria
  7. Nephrotic syndrome

COMPLICATIONS:
- Neurologic complications:
  1. Granuloma of spinal cord or brain
  2. Transverse myelitis
  3. Epilepsy or focal neurologic deficit
  4. Impaired cognitive function
- Pulmonary complications:
  1. Granulomatous pulmonary endarteritis
  2. Pulmonary hypertension
  3. Cor pulmonale
- Other complications include tubal obstruction and infertility
- Recurrent bacteremia and recurrent UTI
- Significant systemic associations: Malnutrition, impaired growth, and development

COMORBIDITIES:
- HIV: Schistosomiasis may increase the risk of HIV infection.
- Hepatitis B and C: People who have coinfection appear to have more severe disease.
- Malaria: Possible protective effect of schistosomiasis on malaria infection.

DX DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Amebiasis
- Bacillary dysentery
- Bowel polyp
- Prostatic disease
- Genitourinary tract cancer
- Bacterial infections of the urinary tract

WORKUP
- Microscopy in urine or stool
- Tissue biopsy (rectal, ideally under direct visualization)
- Serology
- CBC
- LFT
- US of abdomen, including bladder
- CT scan of abdomen
- Urine/serum antigen assay

LABORATORY TESTS
- CBC can show eosinophilia, anemia, thrombocytopenia
- LFT with mild increase in alkaline phosphatase and GGT
- Microscopy: Stool and urine to examine for eggs
- Serology: ELISA for detecting both schistosomal antibodies and antigen, especially for symptomatic travelers
- Limited ability to discern between active and prior infection for patients in endemic regions
- Rectal biopsy or bladder mucosal biopsy
- While not yet in widespread use, PCR testing, particularly in patients previously treated or with negative microscopy and positive serology results

IMAGING STUDIES
- An x-ray of the abdomen shows "fetal head" calcification.
- Sonography can detect thickened bladder wall, hydronephrosis and hydroureter, and bladder polyps or calcification. It can also detect thickened fibrosed portal tracts.
- Esophagoscopy documents esophageal varices.
- Liver biopsy may also demonstrate granuloma and periportal fibrosis (also called Symmer pipestem fibrosis).
- Cystoscopy should be considered in cases of persistent urinary symptoms as there is risk of bladder cancer, even in pediatric cases.

RX TREATMENT

- Oral antihistamines can relieve symptoms of swimmer's itch (reaction from skin penetration of cercariae after water exposure). Regardless, dermatologic symptoms resolve gradually.
- Drug of choice for *S. haematobium* and *S. mansoni* is praziquantel 40 mg/kg of body weight PO in one or two doses. *S. japonicum* and *S. mekongi* require a dose of 60 mg/kg divided in three doses.
- Any pregnant or lactating women with evidence of schistosomiasis should receive treatment with praziquantel. In pregnant women, praziquantel administration is preferred after the first trimester.
- Alternatives: Oxamniquine 15 mg/kg PO once or 20 mg/kg PO daily for 3 days for recalcitrant infections of *S. mansoni* and metrifonate for urinary schistosomiasis, but currently not available.
- Oral steroids are indicated with Katayama fever and central nervous system involvement.

DISPOSITION

Treated patients usually respond to therapy. Definitive cure has occurred only when there is total disappearance of viable eggs from the excreta for a total of 6 mo after treatment. Patients may excrete nonviable eggs for months to years after effective therapy and may require examination to confirm nonviability early after initial treatment.

REFERRAL

- To an infectious disease specialist knowledgeable in parasitology and geographic medicine for treatment and follow-up
- To a gastroenterologist for sclerotherapy of bleeding esophageal varices, if needed in advanced hepatosplenic schistosomiasis
- To a urologist for management and follow-up of urinary complications of *S. haematobium* infection of the genitourinary tract

PEARLS & CONSIDERATIONS

COMMENTS

Prevention:

- Chemotherapy with yearly praziquantel:
  1. Mass, nationwide preventative chemotherapy
  2. Targeted endemic populations
- Snail control:
  1. Mollusciciding (historically not effective)
  2. Environmental modification
  3. Biologic control
- Reduction of water contact and contamination:
  1. Provision of domestic water supplies to prevent exposure to humans
  2. Provision of sanitary disposal of excreta to prevent exposure to snail habitat
- Vaccines are in development
- Improved living standards

Screening:

- Travelers and refugees from endemic areas and those who have been exposed to fresh water:
  1. Serology
  2. Urine and stool microscopy

Schizophrenia

BASIC INFORMATION

DEFINITION

Schizophrenia is a disorder that causes significant distortions in thinking, perception, speech, and behavior. Characteristics include psychosis, apathy, social withdrawal, and cognitive impairment, which result in significant social impairment.

SYNONYM

Dementia praecox

ICD-10CM CODES

F20 Schizophrenia
F20.0 Paranoid schizophrenia
F20.1 Hebephrenic schizophrenia
F20.2 Catatonic schizophrenia
F20.3 Undifferentiated schizophrenia
F20.5 Residual schizophrenia
F20.6 Simple schizophrenia
F20.8 Other schizophrenia
F20.9 Schizophrenia, unspecified

DSM-5 CODE

295.90

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 0.2 per 1000

PREVALENCE: 0.5%; lifetime prevalence risk, 0.4%

PREDOMINANT SEX: Males have a more severe illness with earlier onset. Prevalence in males approximately 1.4 times higher.

PREDOMINANT AGE:

- Age of onset of psychotic symptoms is the early 20s for males and the late 20s for females.
- Age of onset of negative symptoms is usually earlier (i.e., the mid-teenage yr).

PEAK INCIDENCE: Between ages of 16 and 30 yr

GENETICS:

- Genetics accounts for 70% of risk; the remaining 30% associated with other factors such as urban environments, migration, or cannabis use.
- First-degree relatives have a 10 times greater chance of becoming schizophrenic.
- Discordant rates among identical twins are higher than expected with the simple inheritance pattern.
- Associations with several chromosomes have been described, but none has been replicated.
- Evidence exists that triple nucleotide repeat expansion (e.g., such as that seen with Huntington disease) may play a role in the inheritance of the disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Schizophrenia is best defined as a dilapidating illness that begins early in life and that progresses slowly throughout the lifetime.
- Frequent structural brain imaging findings include the enlargement of the ventricular system, a loss of brain volume and cortical gray matter, and an alteration of the white matter tracts.
- The initial "negative" symptoms of adolescence (prodromal phase)—cognitive decline, social withdrawal and awkwardness, loss of motivation and pleasure, and loss of emotional expressiveness—begin after a period of normal development.
- During early adulthood, positive symptoms of psychosis and thought disturbance occur; psychotic symptoms then wax and wane throughout life. Treatment ameliorates positive symptoms, but generally does little for negative ones.
- The condition is also accompanied by cognitive impairment, including problems with attention and concentration, psychomotor speed, learning, memory, and executive functions (e.g., abstract thinking, problem solving, planning).
- Social and occupational dysfunction can be profound.

ETIOLOGY

- The basic determination of whether this is a neurodegenerative or neurodevelopmental condition has not been made.
- The major hypothesis is that abnormality of the mesocortical pathways produces the hypofrontality and the negative symptoms. This occurs along with a compensatory hyperactivation of the mesolimbic pathways, which produces the positive symptoms of psychosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Schizophrenia is diagnosed when an individual has experienced at least 6 mo (1 mo if using ICD-10 criteria) of hallucinations, delusions, thought disorders, catatonia, or negative symptoms (e.g., avolition, anhedonia, social isolation, affective flattening).
- Any medical condition, medicine, or substance that can affect brain homeostasis can cause psychosis; this is distinguished from schizophrenia by a relatively brief course and an alteration in mental status that suggests an underlying delirium.
- Other neurologic conditions that have psychosis as the initial presentation (e.g., Huntington disease) need to be ruled out.
- Mood disorders with psychosis: These are indistinguishable from schizophrenia cross-sectionally but have a longitudinal course that includes full recovery.
- Delusional disorder involves nonbizarre delusions and lacks the thought disturbance, hallucinations, and negative symptoms of schizophrenia.
- Autism in the adult has an early age of onset and lacks significant hallucinations or delusions.

WORKUP

- History and physical examination to help determine whether the psychosis is primary or secondary.
- Neurologic examination to uncover the soft neurologic signs (e.g., clumsiness, cortical thumb, loss of fine motor movements) that are common with schizophrenia.

LABORATORY TESTS

- No laboratory tests are specific.
- Laboratory examinations (e.g., chemistry profile, blood count, sedimentation rate, toxicology screen, and urinalysis) are geared toward excluding a primary medical condition or toxic state. Note that new common drugs of abuse may not be detectable with regular screening tests.

IMAGING STUDIES

- CT or MRI of the brain during the initial workup; repeated if the course of the illness varies from what is expected.
- EEG may reveal slowing when psychosis is the result of an encephalopathy. Findings can be similar as a result of common medication use for treatment of psychosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Significant social support is required by most schizophrenic patients, but available support services are often grossly inadequate. Schizophrenic patients constitute nearly one third of all homeless individuals and approximately 5% of the incarcerated population. They usually require help with basic social, occupational, and interaction skills.
- Family stress can precipitate relapse and re-hospitalization. Family interventions can reduce morbidity.
- Cognitive behavioral therapy can reduce the severity of both psychotic and negative symptoms.
- Illness management training for patients can increase medication adherence and reduce symptom distress.
- Integrated treatment that includes assertive community treatment, family involvement programs, and social skills training reduces the severity of both psychotic and negative symptoms, reduces comorbid substance misuse, reduces hospital days, increases adherence to treatment, and increases satisfaction with treatment.

ACUTE GENERAL Rx

- Acute psychosis is usually adequately controlled with antipsychotic agents.
- Few differences in effectiveness exist between first-generation antipsychotics (e.g., haloperidol, perphenazine, fluphenazine, chlorpromazine) and second-generation antipsychotics (e.g., risperidone, olanzapine, quetiapine, ziprasidone, aripiprazole, clozapine, lurasidone) for nonrefractory patients. First-generation antipsychotics are slightly more likely than second-generation antipsychotics to cause a parkinsonian state and eventual tardive dyskinesia (rate of tardive dyskinesia, 15% to 30%). Antiparkinsonian drugs (e.g., benztropine, amantadine) are used to ameliorate the parkinsonism. Risperidone has been shown to be superior to haloperidol for the prevention of acute psychotic relapse.

- Sedatives (i.e., benzodiazepines and, to a lesser degree, barbiturates) can be used transiently if a patient is in an agitated state. Benzodiazepines like lorazepam are essential for schizophrenic patients who present with catatonia.
- ECT may be needed in cases of catatonic schizophrenia unresponsive to lorazepam.

CHRONIC Rx

- Relapse prevention is a major goal of treatment. Noncompliance is common and leads to high relapse rates. Antipsychotic agents usually must be continued at the same doses that controlled psychosis. For noncompliant patients, long-acting injectable preparations given biweekly, monthly, or every 3 mo can be used.
- Most patients frequently switch among antipsychotics; there is considerable individual variability with regard to antipsychotic response and vulnerability to specific adverse effects.
- Clozapine is more effective than other agents for treatment-refractory patients. However, it requires monitoring to prevent life-threatening adverse effects. Regular monitoring of WBC and absolute neutrophil count (ANC) during the therapy is required due to a greater risk of developing agranulocytosis.
- Olanzapine may also be more effective than less expensive first-generation drugs but has substantial adverse metabolic effects. Lurasidone is a newer second-generation antipsychotic that appears to be better tolerated, but longer-term studies are needed.
- Neurocognitive improvement associated with antipsychotic treatment among patients with schizophrenia is small and does not differ between first-generation and second-generation antipsychotics.
- Antiparkinsonian agents may also need to be continued for the long term.
- Tardive dyskinesia (i.e., choreoathetoid movements of the muscles of tongue and face and occasionally of other muscle groups) can occur in as many as 30% of patients with the long-term use of neuroleptics.
- The negative symptoms of schizophrenia can resemble depression. In addition, depressive disorders may occur in schizophrenic patients. Antidepressant treatment of the negative symptoms is usually not effective. However, antidepressants can improve the symptoms of a comorbid depressive episode.
- Mood stabilizers (e.g., lithium, valproate, carbamazepine) are of little use unless the patient has a comorbid impulse control disorder.
- Substance abuse is a major problem for more than a third of schizophrenic patients. More than half of these patients smoke cigarettes. Unfortunately, these individuals do poorly in traditional substance abuse treatment programs. Specialized "dual-diagnosis" programs with highly structured aftercare are required.
- Specific antipsychotic medications have been associated with weight gain (i.e., olanzapine and clozapine) and QT prolongation. Hyperlipidemia and diabetes mellitus are associated with second-generation antipsychotics, and hyperprolactinemia is associated with first-generation antipsychotics. (Risperidone, a second-generation antipsychotic, can also produce hyperprolactinemia.) Clozapine is associated with agranulocytosis and a decrease in intestinal motility, which can lead to bowel obstruction. Metabolic status and weight should be screened before the start of treatment and at regular intervals.
- Patients with schizophrenia have a higher lifetime incidence of suicide, with 20% attempting on one or more occasions and 5% to 10% completing suicide. Comorbid use of substances and hopelessness are associated risk factors. Clozapine has shown the ability to decrease the incidence of suicidal attempts in schizophrenia patients.
- Several first- and second-generation antipsychotics are available in long-acting injectable preparations that may be helpful in addressing issues of poor compliance or difficulty when treatment needs to be supervised. Current preparation can be given in intervals that range between every 2 to every 3 mo. Consider economic factor and importance of regular checks when using long-acting injectables.

DISPOSITION

- The positive symptoms of as many as 20% to 30% of schizophrenic patients do not respond to available treatments. A much higher fraction of patients experience relapse as a result of poor compliance.
- Negative symptoms are responsible for the 50% to 70% of patients in whom deterioration in occupational and social function continues.
- Approximately 5% to 10% of schizophrenic patients will complete suicide.
- The course of the illness is most strongly predicted by the level of social development attained at the onset of psychosis.
- Schizophrenic patients die 12 to 15 yr sooner than the average population, mostly as a result of physical causes related to a lack of access to health care or as a result of health risk factors (e.g., smoking, obesity).

REFERRAL

- If hospitalization is required
- If patient is noncompliant
- If patient is resistant to treatment

PEARLS & CONSIDERATIONS

- Rule out delirium caused by medical conditions, medications, or substance abuse before diagnosing an individual's psychotic behavior as schizophrenia.
- All antipsychotic medications have high discontinuation rates in chronic schizophrenia treatment. Olanzapine and clozapine may be more effective than other antipsychotics for chronic treatment, but they have significant side effects.
- Significant social support is required for most patients with schizophrenia. Nonpharmacologic therapy should be used in conjunction with pharmacotherapy.

BASIC INFORMATION

DEFINITION

Sciatica refers to the neuralgia following the sciatic nerve down the leg along its distribution. Sciatica usually occurs unilaterally. Pain is described as sharp or aching, and it typically radiates from the buttock down the leg posteriorly, laterally, or anteriorly depending on the level of nerve root compression.

SYNONYMS

Bilateral sciatica
Deep gluteal syndrome
Gout of the hip
Ischialgia
Left-sided sciatica
Low back pain with left sciatica
Low back pain with right sciatica
Low back pain—sciatica
Lumbago with sciatica
Lumbar nerve root pain
Lumbar radiculopathy (LBP)—sciatica
Neuropathy—sciatic nerve
Right-sided sciatica
Sciatic nerve dysfunction
Sciatic neuritis

ICD-10CM CODES

G57.00	Lesion of sciatic nerve, unspecified lower limb
G57.01	Lesion of sciatic nerve, right lower limb lesion
G57.02	Lesion of sciatic nerve, left lower limb
M54.30	Sciatica, unspecified side
M54.31	Sciatica, right side
M54.32	Sciatica, left side
M54.40	Lumbago with sciatica, unspecified side
M54.41	Lumbago with sciatica, right side
M54.42	Lumbago with sciatica, left side
M54.5	Low back pain
M54.9	Dorsalgia, unspecified
M62.838	Other muscle spasm

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Very few studies have determined the incidence of sciatica. However, 5% to 10% of patients with low back pain have sciatica. The highest incidence recorded is 40%.
PEAK INCIDENCE: Age 30 to 64 yr
PREVALENCE: Annual prevalence of disc-related sciatica in the general population is estimated at 2.2%.
RISK FACTORS:

- Increasing risk with height
- Smoking
- Diabetes
- Obesity
- Prolonged sitting and sedentary lifestyle
- Occupational factors:
  1. Strenuous physical activity (e.g., frequent lifting while bending and twisting)
  2. Driving

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Unilateral leg pain greater than low back pain
- Pain radiating to foot or toes
- Numbness and paresthesia in the same distribution
- Straight leg raising test induces more leg pain
- Localized neurology limited to one nerve root

ETIOLOGY

- Sciatica is usually caused by disc herniation at the L4 to L5 and L5 to S1 level, less commonly at the L3 to L4 level.
- Other causes include lumbar spinal stenosis, facet joint osteoarthritis or other arthropathies, spinal cord infection or tumor, sacroiliac joint dysfunction, degenerative disc disease, or isthmic spondylolisthesis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nonspecific low back pain
- Piriformis syndrome
- Muscular problems (sprain, spasm)
- Vascular problems (claudication, compartment syndrome)
- Chronic edema
- Box 1 summarizes the differential diagnosis for low back pain

WORKUP

History taking and the physical examination are important steps in the evaluation of sciatica. Historical clues to the cause of low back pain are summarized in Table 1. Red flags that may indicate cauda equina or spinal infection mandate emergent workup. Fig. 1 summarizes an algorithm for the management of low back pain.
HISTORY TAKING:

- Severity of pain
- Duration
- Influence of coughing, movement, or rest
- Complaints of radiating pain in the leg following a dermatomal pattern
- Low back pain, less severe than leg pain
- Pain generally radiates below the knee, into the foot
- Dermatome maps used to locate origin of the pain
- Sensory symptoms

PHYSICAL EXAMINATION: Neurological testing

- Myotomes
- Reflexes (L4 to S3)
- Sensations (dermatomes; see Fig. 2)

LUMBAR MOBILITY ASSESSMENT: Neural tension tests (preferable seated position)

- Straight leg raise test
- Reversed straight leg raise test
- Bragard test
- Crossed straight leg raise test
- Slump test
- Femoral nerve tension test

BOX 1 Differential Diagnosis for Low Back Pain

Localized and Common
Uncomplicated musculoskeletal back pain
Intervertebral disk herniation
Spinal stenosis
Spondylolisthesis
Osteoarthritis
Fracture

Localized and Uncommon
Infection
Spondylitis
Epidural abscess
Diskitis
Herpes zoster

Malignancy
Metastatic
Breast
Lung
Prostate
Kidney, thyroid, colon (less common)
Primary
Multiple myeloma
Lymphoma
Leukemia
Primary cord or extradural tumors
Osteoid osteoma
Other primary bone tumors

Pediatric
Spondylolisthesis, spondylolysis
Severe scoliosis
Scheuermann disease

Rheumatologic
Ankylosing spondylitis
Psoriatic arthritis
Polymyalgia rheumatica
Reiter syndrome

Vascular
Arteriovenous malformation of spinal cord
Epidural hematoma

Life-Threatening Referred Pain
Abdominal aortic aneurysm

Gastrointestinal System
Biliary pathology
Pancreatitis
Peptic ulcer disease
Diverticulitis

Genitourinary System
Renal colic
Pyelonephritis
Prostatitis
Cystitis

Gynecologic System
Menstrual cramps
Spontaneous abortion
Labor
Ectopic pregnancy
Pelvic inflammatory disease
Endometriosis
Ovarian cyst
Ovarian torsion

Hematologic System
Sickle cell crisis

Functional
Somatization disorder
Depression
Fibrositis
Malingering

From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, Elsevier.

TABLE 1 Historical Clues to the Cause of Low Back Pain

Questions for Patient	Potential Diagnosis
Does the back pain radiate down past the knees?	Radiculopathy and likely a herniated disk
Is the pain worse with walking and better with bending forward and sitting?	Spinal stenosis
Do you have morning back stiffness that improves with exercise?	Ankylosing spondylitis
Are you older than 50 yr?	Osteoporotic fracture, spinal malignancy
Has there been any recent history of blunt trauma?	Fracture
Do you take long-term corticosteroids?	Fracture, spinal infection
Do you have a history of cancer?	Spinal metastatic malignancy
Does your pain persist at rest?	Spinal malignancy, spinal infection
Has there been persistent pain for longer than 6 wk?	Spinal malignancy
Has there been unexplained weight loss?	Spinal malignancy
Is the pain worse at night?	Spinal malignancy, spinal infection
Are you immunocompromised (e.g., HIV infection, alcoholism, diabetes)?	Spinal infection
Have you had fevers or chills?	Spinal infection
Do you have pain, weakness, or numbness in both legs?	Cauda equina syndrome
Do you have bladder or bowel control problems?	Cauda equina syndrome

HIV, Human immunodeficiency virus.
From Walls RM et al: *Rosen's emergency medicine: concepts and clinical practice*, ed 9, Philadelphia, 2018, Elsevier.

Major maneuvers:
- Lumbar lateral bending
- Hip flexion
- Lasegue test
- Bechterew test
- Fajersztajn test
- Knee extension

Minor maneuvers:
- Cervical flexion
- Spinal flexion
- Hip internal rotation
- Hip adduction
- Great toe dorsiflexion
- Increased intrathecal/intradiscal pressure

LABORATORY TESTS

No laboratory tests specifically identify sciatica; it is a clinical diagnosis.
- Occasionally laboratory tests such as complete blood count (CBC) may suggest infection, anemia due to certain cancers, or other unusual causes of sciatica.
- Elevated erythrocyte sedimentation rate may suggest inflammation somewhere in the body.
- Urinalysis may suggest a kidney stone if there is blood in the urine, or infection if bacteria and white blood cells are present in the urine.

IMAGING STUDIES

- If pain does not resolve on its own, computed tomography (CT) or magnetic resonance imaging (MRI) scans of spine can be ordered to evaluate for other causes.
- If patient has a history of cancer, HIV infection, or IV drug use, or has been taking steroids over a period of time, imaging or bone scan are recommended.
- Electromyography (EMG).
- X-ray of spine may be examined for compression of nerve due to bone overgrowth.

Rx TREATMENT

Treatment for sciatica is activity modification and pain medication.

- Prescription-strength nonsteroidal anti-inflammatory drugs, such as meloxicam and diclofenac
- Analgesics, such as acetaminophen
- Muscle relaxants, such as cyclobenzaprine and tizanidine
- Corticosteroids
- Nerve pain medication (e.g., gabapentin)
- If pain is severe and not relieved by previous measures, then narcotic medications may be prescribed for a short period

NONPHARMACOLOGIC THERAPY

- Back surgery may be recommended if the pain continues and the CT and MRI indicate an anatomic problem with disc or bone and all other methods of treatment do not work. In a recent trial[1] involving patients with sciatica lasting more than 4 mo and caused by lumbar disk herniation, microdiskectomy was superior to nonsurgical care with respect to pain intensity at 6 mo of follow-up
- Ice or heat on affected area for 20 min every 2 hr
- Physical therapy
- Acupuncture, relaxation techniques
- Epidural injections
- Exercise therapy, including walking, yoga, Pilates
- Reducing pressure on the nerve root
- Bed rest is not recommended

ACUTE GENERAL Rx

- Acetaminophen for mild pain.
- Prescription-strength nonsteroidal anti-inflammatory drugs, such as meloxicam and diclofenac for moderate pain. Muscle relaxants, such as cyclobenzaprine and tizanidine are frequently used but efficacy is questionable. They are contraindicated in elderly patients.
- Gabapentin or pregabalin are frequently prescribed, but trials have failed to show reduced intensity of leg pain or improved outcomes.

[1]Bailey CS et al, Surgery versus conservative care for persistent sciatica lasting 4 to 12 months, *N Engl J Med* 382(12):1093-1102, 2020.

CHRONIC Rx

If pain is severe and not relieved by previous measures, then narcotic medications may be considered for a short period, although the medical community is increasingly turning away from long-term opioids due to the associated morbidity and mortality

COMPLEMENTARY AND ALTERNATIVE MEDICINE

- Acupuncture
- Spinal manipulation/chiropractic treatment techniques
- Physical therapy

DISPOSITION

Outpatient workup and assessment, including:
- Checking for red flags that may indicate malignancies, osteoporotic fractures, infection, or cauda equina syndrome
- Taking a history to determine localization, severity, loss of strength, sensation, duration, course, influence of coughing, rest or movement
- Physical examination, including straight leg raising test
- Imaging or laboratory diagnostic testing if red flags are present
- Prescribe medication as needed

REFERRAL

- Orthopedic surgeon
- Pain management
- Physical therapist
- Refer to neurosurgeon immediately in cases of cauda equina syndrome or acute severe paresis or progressive paresis (within a few days)
- Refer to neurologist, neurosurgeon, or orthopedic surgeon for consideration of surgery in cases of intractable radicular pain (not responding to morphine) or if pain does not diminish after 6 to 8 wk of conservative care

PEARLS & CONSIDERATIONS

COMMENTS

- Most people recover fully from sciatica and often without treatment, but it can potentially cause nerve damage. Important to seek immediate medical attention with loss of feeling in affected leg, weakness in affected leg, or loss of bowel or bladder function, as this could indicate cauda equina or epidural abscess.
- Sciatica does have a tendency to recur.
- Bed rest is not recommended.

PREVENTION

- Exercise regularly.
- Maintain proper posture when you sit.
- Use good body mechanics.

BASIC INFORMATION

DEFINITION

Scleritis is inflammation of the sclera (the fibrous layer of the eye underlying the conjunctiva and episclera). It is characterized by edema and cellular infiltration of the entire thickness of the sclera.

Classification of immune-mediated scleritis:

- Anterior nonnecrotizing scleritis: Can be subdivided into diffuse or nodular.
- Anterior necrotizing scleritis with inflammation: Can be subdivided into vasoocclusive, granulomatous, or surgically induced. Aggressive form of scleritis. Average age of onset is 60 yr. Bilateral in 60% of patients.
- Scleromalacia perforans: Typically affects elderly women with longstanding rheumatoid arthritis.
- Posterior scleritis: Involves the deeper tissues of the eye and is potentially blinding. Age of onset is often under 40 yr. Bilateral in 35% of cases.

SYNONYMS

Anterior scleritis
Diffuse nodular, necrotizing scleritis
Scleromalacia perforans
Scleral melt syndrome

TABLE E1 Classification of Immune-Mediated (Noninfectious) Scleritis

Anterior

- Nonnecrotizing
  - Diffuse
  - Nodular
- Necrotizing with inflammation
  - Vasoocclusive
  - Granulomatous
  - Surgically induced (can also be infective)
- Scleromalacia perforans (necrotizing without inflammation)

Posterior

From Bowling B: *Kanski's clinical ophthalmology, a systemic approach*, ed 8, Philadelphia, 2016, Elsevier.

ICD-10CM CODES
H15.0 Scleritis
H15.1 Episcleritis

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Increases with increasing age
INCIDENCE (IN U.S.): Busy ophthalmologists may see one or two cases/yr
PREVALENCE (IN U.S.): Relatively rare
PREDOMINANT SEX: 61% women
PREDOMINANT AGE: 52 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Deep, boring (dull) eye pain that may awaken patient from sleep
- Photophobia
- Tearing
- Painful eye movements
- Globe is tender to touch
- Conjunctival injection
- Thinning of the sclera
- An underlying systemic autoimmune disease is found in >50% of patients. Most common rheumatic problem is rheumatoid arthritis. Most patients with systemic disease are diagnosed before development of scleritis

ETIOLOGY

- Inflammatory (seen with rheumatoid arthritis, granulomatosis with polyangiitis [Wegener granulomatosis], relapsing polychondritis, polyarteritis nodosa), lupus, sarcoidosis. A classification of immune-mediated scleritis is described in Table E1.
- Allergic.
- Infectious scleritis (herpes zoster, tuberculosis, Lyme disease, syphilis, *Pseudomonas aeruginosa, Nocardia,* leprosy) is uncommon, accounting for 4% to 18% of cases.
- Approximately 50% of patients with scleritis have an underlying systemic disease (vasculitis, infectious disease).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Most common causes are rheumatoid arthritis and other collagen-vascular diseases.

- Occasionally there are allergic, infectious, or traumatic causes.
- Conjunctivitis, iritis, and episcleritis should be considered in the differential diagnosis. Patients with episcleritis generally have less pain and vision is unaffected.

WORKUP

- Eye examination. Figs. E1 to E6 illustrate the various types of scleritis
- Visual field examination
- Workup for autoimmune disease (e.g., vasculitis, collagen vascular diseases)

LABORATORY TESTS

Rheumatoid factor, antinuclear antibody, erythrocyte sedimentation rate, ANCA (c-ANCA, p-ANCA), antiphospholipid antibodies, HLA-B27 may be useful for underlying etiology

IMAGING STUDIES

Usually not necessary; CT scan of orbit may be useful in selected patients for collagen vascular disease or vasculitis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Bandage lenses
- Surgery if thinning of the sclera is severe to prevent eye rupture

ACUTE GENERAL Rx

Immunotherapy:

- Steroids (topical, periocular, and systemic)
- Cycloplegic drops
- NSAIDs (topical and systemic); systemic more effective than topical. Some NSAID and

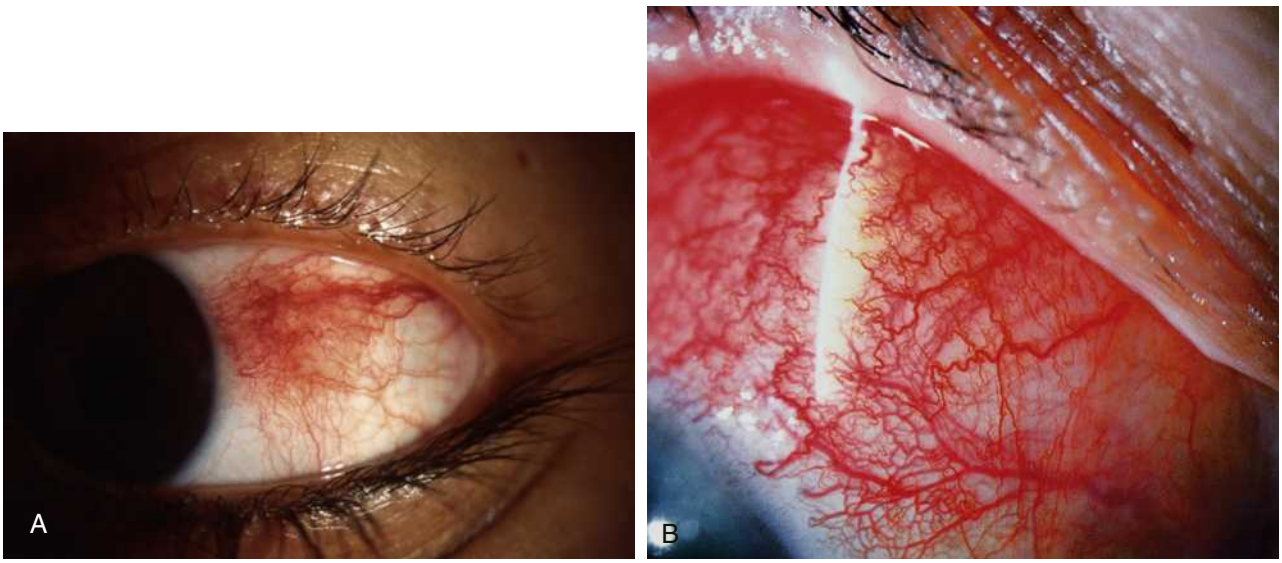

FIG. E1 Simple episcleritis. A, Sectoral. **B,** Diffuse. (Courtesy of JH Krachmer, MJ Mannis, and EJ Holland, from *Cornea*, 2005, Mosby; **B,** from Bowling B: *Kanski's clinical ophthalmology: a systemic approach*, ed 8, Philadelphia, 2016, Elsevier.)

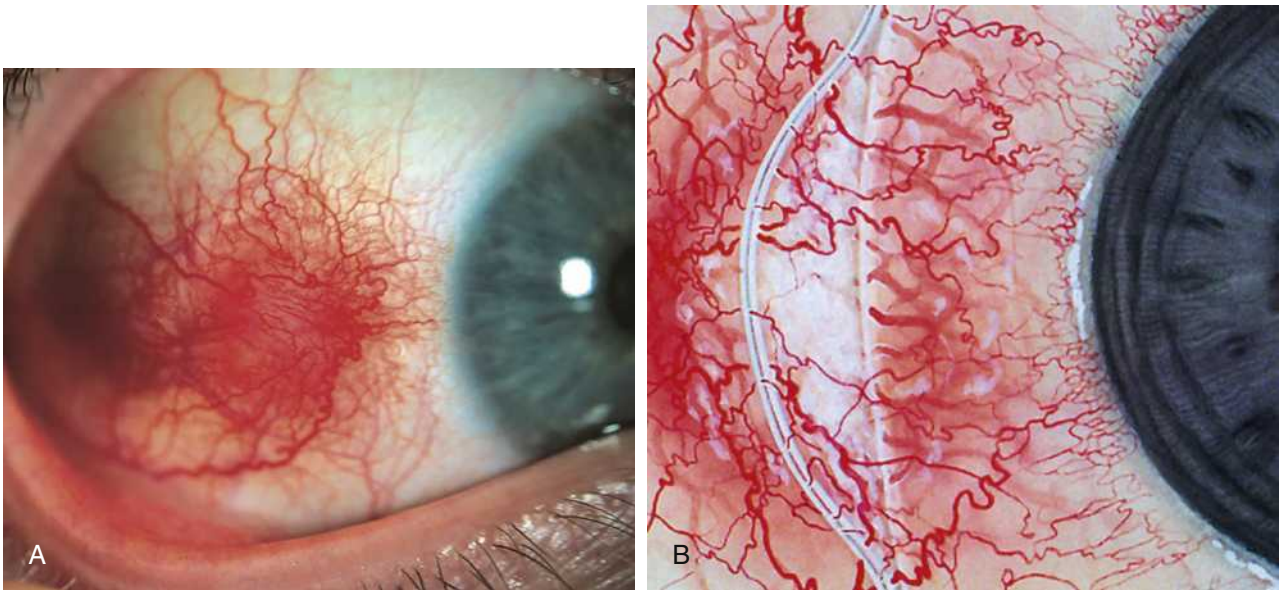

FIG. E2 A, Nodular episcleritis. **B,** Slit illumination shows that the deep beam is not displaced above the scleral surface. (From Bowling B: *Kanski's clinical ophthalmology: a systemic approach*, ed 8, Philadelphia, 2016, Elsevier.)

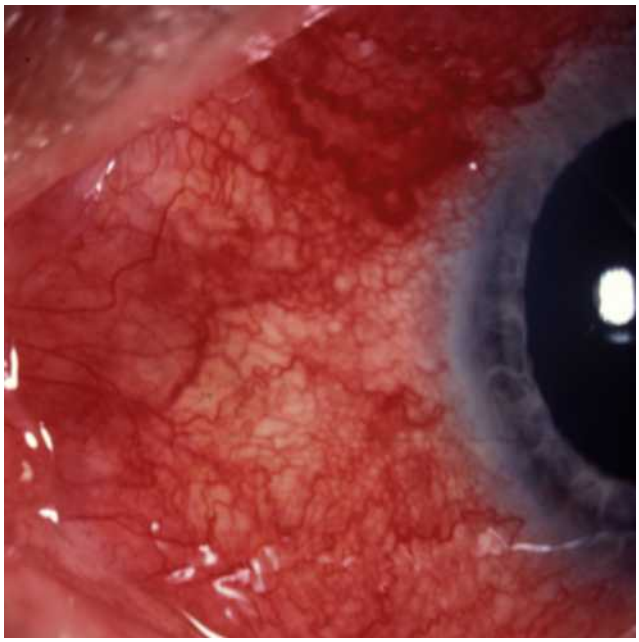

FIG. E3 Diffuse nonnecrotizing anterior scleritis. (From Bowling B: *Kanski's clinical ophthalmology: a systemic approach*, ed 8, Philadelphia, 2016, Elsevier.)

steroid drops have been shown to increase risk of corneal peripheral ulceration, so should be closely observed
- Cytotoxic agents (cyclophosphamide, azathioprine, mycophenolate mofetil, methotrexate) for severe unresponsive cases
- Immune modulators (cyclosporin, tacrolimus)
- Specific antibodies (infliximab, rituximab)

CHRONIC Rx

- Systemic corticosteroids can be given for the underlying disease.
- Local steroids may be helpful. Topical steroids should be used judiciously since these can potentiate the collagenase activity and worsen the scleral loss.
- Control underlying disease.

DISPOSITION

Urgent referral to ophthalmologist because this disorder can be a sight-threatening condition.

REFERRAL

Should be managed by ophthalmologist; complications of scleritis can be severe, including scleral melt, inflammation, corneal involvement. An ophthalmologist may also enlist the help of a rheumatologist for severe cases that may require long-term immunotherapies.

PEARLS & CONSIDERATIONS

COMMENTS

Necrotizing scleritis can be an ominous diagnosis because these patients often have other severe underlying debilitating vasculitic disease processes.

Scleroderma (Systemic Sclerosis)

BASIC INFORMATION

DEFINITION

Scleroderma or systemic sclerosis (SSc) is a term used to describe a connective tissue disorder that is characterized by thickening and fibrosis of the skin. Scleroderma is divided into two forms: Localized scleroderma and systemic sclerosis. Systemic sclerosis is a multiorgan disease characterized by fibrosis and vasculopathy. Skin thickening without any organ involvement is known as localized scleroderma and includes three subset conditions (see Box 1). Systemic sclerosis includes skin fibrosis along with variable severe involvement of diverse internal organs. It is further divided into two major subgroups: (1) Limited cutaneous SSc (lcSSc), which involves skin thickening of the face, neck, and distal to the elbows and knees; and (2) diffuse cutaneous SSc (dcSSc), which affects the skin in a more generalized distribution including the proximal and distal extremities, face, neck, and trunk. Clinical features of the major subsets of systemic sclerosis are summarized in Box 2.

SYNONYMS

SSc
Systemic sclerosis
Morphea applies to localized scleroderma that affects only the skin.
Scleredema is a disease of the skin that mimics but is distinct from scleroderma.

ICD-10CM CODES

L94.0	Localized scleroderma (morphea)
L94.1	Linear scleroderma
M34.0	Progressive systemic sclerosis
M34.1	CREST syndrome
M34.2	Systemic sclerosis induced by drug and chemical
M34.81	Systemic sclerosis with lung involvement
M34.82	Systemic sclerosis with myopathy
M34.83	Systemic sclerosis with polyneuropathy
M34.89	Other systemic sclerosis
M34.9	Systemic sclerosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

Incidence and prevalence of SSc differs between studies due to variations between geographic regions and time periods.

BOX 1 Classification of Scleroderma

I. Localized scleroderma
  A. Morphea
  B. Linear scleroderma
  C. Scleroderma en coup de sabre
II. Systemic sclerosis
  A. Limited cutaneous systemic sclerosis
  B. Diffuse cutaneous systemic sclerosis

From Hochberg MC, et al.: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

INCIDENCE: There are an estimated 19 cases per 1 million persons/yr, but many mild cases go unrecognized.
PREVALENCE: 276 cases per 1 million persons per yr
PREDOMINANT SEX: Female/male ratio of 4:1
PREDOMINANT AGE: 30 to 50 yr
DISTRIBUTION: Worldwide

PHYSICAL FINDINGS & CLINICAL PRESENTATION

PHYSICAL FINDINGS:

- Skin:
  1. Initial presentation of puffy hands and fingers may occur in some patients.
  2. Tightening of the skin begins on the hands and then can progress to the forearms, face, and neck. The skin is shiny, taut, and sometimes red, with loss of creases and hair. Skin thickening involving the fingers or toes is known as sclerodactyly (Fig. E1). Skin involvement in scleroderma is classified as lcSSc or dcSSc, depending on the distribution of the skin thickening (see previously) (Fig. E2). Fig. E3 illustrates the method used to quantify skin thickness in scleroderma.
  3. Skin tightening may limit movement by causing flexion contractures of the fingers, wrists, and elbows. Perioral skin tightening (Fig. E4) results in decreased oral aperture, furrowing around the lips, and dry membranes.
  4. Pigmentary skin changes (hypo or hyperpigmentation) may occur (e.g., "salt and pepper").
  5. Telangiectasias (dilated capillaries) may be seen on face, hands, mucous membranes (Fig. E4), and trunk.
  6. Subcutaneous calcinosis, calcinosis cutis
  7. In dsSSc patients, the skin fibrosis can soften over time (generally occurring at least 2 yr after onset of skin manifestation), with improved joint mobility.
  8. Skin atrophy and thinning can also occur in the late stages of SSc.
- Musculoskeletal:
  1. Arthralgias and swelling
  2. Inflammatory arthritis, tendinitis
  3. Myalgias, myopathy
  4. Joint contractures
  5. Tendon friction rubs (physical exam finding of a palpable rub felt over tendon sheaths—fingers, wrists, elbows, knees, and/or ankles)
- Gastrointestinal involvement:
  1. Esophageal dysmotility with heartburn
  2. Esophageal stricture with dysphagia and odynophagia
  3. Delayed gastric emptying
  4. Gastrointestinal bleeding from mucosal telangiectasias, gastric antral vascular ectasias, or gastritis
  5. Small bowel dysmotility with abdominal cramps, bloating, and diarrhea
  6. Colon dysmotility with constipation
  7. Intestinal bacterial overgrowth resulting in irregular bowel movements (diarrhea alternating with constipation)
  8. Pseudo-obstruction (functional ileus)
  9. Primary biliary cholangitis
- Pulmonary:
  1. Interstitial lung disease (ILD): Pulmonary fibrosis with symptoms of dyspnea and nonproductive cough as well as fine inspiratory crackles on examination. Seen in both lcSSc and dcSSC, but it is more common and severe in dcSSC
  2. Pulmonary arterial hypertension (PAH): Presenting with dyspnea and/or fatigue. Can be identified in both lcSSc and dcSSc, but it is more commonly seen in lcSSc
- Cardiac:
  1. Pericarditis or pericardial effusion
  2. Myocardial fibrosis or ischemia that can lead to CHF or arrhythmias
  3. Left or right systolic or diastolic dysfunction
- Renal:
  1. Rapidly progressive renal failure also known as scleroderma renal crisis (SRC): New-onset hypertension, anemia with schistocytes on peripheral blood smear, thrombocytopenia and renal insufficiency with active urinary sediment and proteinuria

BOX 2 Clinical Features of the Major Subsets of Systemic Sclerosis

Limited SSc
- Skin sclerosis, distal limbs and face
- Long preexisting RP symptoms
- Lower frequency of severe lung fibrosis and renal crisis
- High burden of nonlethal morbidity

Diffuse SSc
- Proximal skin sclerosis
- Shorter preexisting RP history
- High frequency of severe lung fibrosis
- Increased risk of scleroderma renal crisis
- Inflammatory skin changes and pruritus common for first 1-3 yr

Sine SSc
- Features of RP with scleroderma-associated ANA reactivity and at least one internal organ manifestation of SSc
- Frequency uncertain because of likely underdiagnosis

Overlap SSc
- Cases that fulfill classification criteria for SSc and that are diagnosed as SSc but also show features of another autoimmune rheumatic disease
- Most often myositis
- Other cases of lupus, arthritis, or vasculitis
- Comprise up to 20% of SSc cohorts

ANA, Antinuclear antibody; *RP,* Raynaud phenomenon; *SSc,* systemic sclerosis.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

- Vascular:
  1. Raynaud phenomenon (RP): Vasospasm of the fingers with exposure to cold, resulting in color changes of the digits along with numbness/tingling and discomfort
  2. Complications of vascular involvement can include digital pitted scars or ulcers, nonreversible ischemic changes with impending tissue loss, dry gangrene, and auto-amputation
  3. Nailfold capillary abnormalities: Seen with nailfold capillaroscopy, including capillary dilatation, avascularity, or "drop out" of capillaries
- Other organ involvement:
  1. Hypothyroidism
  2. Erectile dysfunction
  3. Sjögren syndrome
  4. Entrapment neuropathies
  5. Depression

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Raynaud phenomenon: Initial complaint in 70% of patients (NOTE: The prevalence of Raynaud phenomenon is 5% to 10% in the general population; most cases do not progress to scleroderma)
- Finger or hand swelling that is sometimes associated with carpal tunnel syndrome
- Arthralgias/arthritis
- Internal organ involvement (Table E1, Table E2, Fig. E5, Fig. E6)
- LcSSc (previously known as CREST syndrome): Calcinosis, Raynaud phenomenon, Esophageal dysmotility, Sclerodactyly telangiectasias—skin fibrosis is limited to the distal extremities. This acronym is now considered obsolete by many because it does not accurately reflect the burden of internal organ involvement

ETIOLOGY

The etiology of this condition is unknown, but genetic and environmental factors (infectious agents, occupational exposures, drugs) contribute to the manifestation of the disease. Genetic profiles show clustering of different alleles according to the subtype of SSc.

Pathologically, small- and medium-sized arteries become injured, leading to fibrin deposition and ultimately luminal occlusion, causing chronic tissue hypoxia. There is also an abnormal selection of fibroblasts and aberrant control of connective tissue synthesis by fibroblasts and other cells. This fibrosis occurs in different organs, causing dysfunction and eventual failure. Although there are characteristic autoantibodies detected, it is not clear that they directly participate in the pathogenesis of the disease.

DIAGNOSIS

The American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) have created criteria as a guide in diagnosing and classifying SSc (Table 3). These include a scoring system for both clinical and laboratory findings (sclerodactyly, fingertip lesions, telangiectasias, abnormal nailfold capillaries, Raynaud phenomenon, PAH/ILD, and SSc-related autoantibodies).

DIFFERENTIAL DIAGNOSIS

DERMATOLOGIC:

- Scleredema
- Amyloidosis
- Porphyria cutanea tarda
- Eosinophilic fasciitis
- Reflex sympathetic dystrophy
- Nephrogenic systemic fibrosis
- Table 4 summarizes distinguishing features of scleroderma and scleroderma-like conditions

SYSTEMIC:

- Idiopathic pulmonary fibrosis
- Primary pulmonary hypertension
- Primary biliary cirrhosis
- Cardiomyopathies
- Gastrointestinal dysmotility problems
- Systemic lupus erythematosus and overlap syndromes

WORKUP

Laboratory tests and imaging studies

TABLE 3 ACR/EULAR 2013 Classification Criteria for Systemic Sclerosis*

Item	Subitem	Weight or Score
Skin thickening of fingers on both hands extending proximal to the MCP joints (sufficient criterion)	—	9
Skin thickening on the fingers (only count the higher score)	Puffy fingers	2
	Sclerodactyly of fingers (distal to MCP joints but proximal to proximal interphalangeal joints)	4
Fingertip lesions (only count higher score)	Digital tip ulcers	2
	Fingertip pitting scars	3
Telangiectasia	—	2
Abnormal nailfold capillaries	—	2
Pulmonary arterial hypertension or ILD (maximum score, 2)	PAH	2
	ILD	2
Raynaud phenomenon	—	3
SSc-related antibodies (anti-centromere, anti-topoisomerase 1 [anti-SCL-70], anti-RNA polymerase III (max score 3)	Anti-centromere	3
	Anti-topoisomerase I	
	Anti-polymerase III	

*The score is determined by adding the maximum weight or score in each category. Patients with scores ≥9 have definite systemic sclerosis (SSc).

ACR, American College of Rheumatology; *EULAR,* European League Against Rheumatism; *ILD,* interstitial lung disease; *MCP,* metacarpophalangeal; *PAH,* pulmonary arterial hypertension; *SSc,* systemic sclerosis.

From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

TABLE 4 Distinguishing Features of Scleroderma and Scleroderma-like Conditions

Condition	Skin Changes and Distribution	Extradermal Involvement	Dermatopathology	Other
Localized scleroderma	Amorphous plaques (morphea) or lines involving the face (linear) and extremities and sparing the fingers	None	Dermal sclerosis, mononuclear inflammation	Linear especially common in children, autoantibodies common
Scleredema	Trunk, back, neck	Rare	Swollen collagen bundles, mucin accumulation	
Scleromyxedema	Induration, sclerodactyly Limited mouth opening	Rare	Excessive dermal mucin deposition	Serum paraprotein (especially IgG λ)
Nephrogenic systemic fibrosis	Extremities, fingers; symmetric	Frequent, mild (muscle, fascia, lungs)	Fibroblast proliferation, mucin deposition, dermal spindle cell proliferation	After gadolinium exposure in end-stage renal disease
Eosinophilic fasciitis	Extremities, trunk; spares fingers	Rare; low-grade myositis	Dermal and hypodermal sclerosis, normal epidermis, muscle inflammation occasionally	Peripheral blood eosinophilia frequent

From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

LABORATORY TESTS

- Antinuclear antibodies (ANA): Nucleolar (more common), homogeneous, or speckled patterns
- Rheumatoid factor positive in 20% of patients
- Routine biochemistry tests may indicate specific organ involvement (e.g., liver, kidney, muscle); should check CBCD, CK, CMP, UA

The following extractable nuclear antigens are either present or absent in SSc:

- Anticentromere antibodies: Generally positive in one third of patients with lcSSc
- Anti-Scl-70 antibody (antitopoisomerase I): Positive in 40% of patients with dcSSc and has an increased risk of developing ILD
- Anti-RNA polymerase III antibody: Portends a worse prognosis, with rapidly progressive skin fibrosis and increased risk of developing SRC. May also indicate increased cancer risk
- Anti-ribonucleoprotein (anti-RNP): Positive in 20%, can see with overlap conditions
- Other possible antibodies include U3 RNP, U1 RNP, PM-Scl, Th/To, Anti-Ku
- Table 5 summarizes autoantigens and autoantibodies in scleroderma

IMAGING AND OTHER STUDIES

- Arthritis: Joint radiographs
- Gastrointestinal:
  1. Upper endoscopy (diagnostic procedure of choice; may be therapeutic)
  2. Cine-esophagography (in rare circumstances)
  3. Barium swallow (occasionally indicated)
  4. Esophageal manometry
- Pulmonary:
  1. Chest x-ray
  2. Pulmonary function tests (especially single-breath diffusion capacity for carbon monoxide—DLCO)
  3. Thoracic high-resolution computed tomography (HRCT) scan
  4. Bronchoscopy with biopsy, bronchoalveolar lavage
- Cardiac:
  1. ECG
  2. Ambulatory (Holter) ECG monitoring
  3. Echocardiography (screen for pulmonary arterial hypertension)
  4. Cardiac catheterization
- Kidney: Renal biopsy
- Skin: Skin biopsy
- Vascular: Nailfold capillaroscopy

Rx TREATMENT

Currently, there is no disease-modifying therapy available for SSc. Generally, the internal organ involvement of the disease is treatable. Fig. 7 illustrates management strategies in SSc. Immunosuppressive agents are used in individual patients. Prednisone should be used with extreme caution, especially in doses >20 mg/day (can precipitate SRC).

- Raynaud phenomenon:
  1. Keep hands and body warm
  2. Avoid smoking and using vasoconstricting drugs
  3. Calcium channel blockers (i.e., long-acting dihydropyridines)
  4. Peripheral α1-adrenergic blockers
  5. Angiotensin II receptor blockers
  6. Topical nitrate
  7. Phosphodiesterase inhibitors
  8. Stellate ganglion blockades
  9. Digital sympathectomy
  10. Table E6 summarizes vascular therapies for Raynaud phenomenon
- Arthralgias: NSAIDs or low-dose corticosteroids (5-10 mg of prednisone per day)
- Myositis: Methotrexate or azathioprine with low-dose corticosteroids
- Skin: For skin fibrosis, immunomodulatory drugs have been used, generally started within 3 yr of onset (methotrexate, mycophenolate mofetil). Cyclophosphamide can be used for refractory or rapidly progressive involvement. Table E7 summarizes immunomodulatory and antifibrotic strategies for disease-modifying treatment of systemic sclerosis skin disease
- GI tract: Table E8 summarizes treatment of GI tract complications in systemic sclerosis
- Esophageal reflux:
  1. H_2-receptor blockers
  2. Proton pump inhibitors
- Interstitial lung disease:
  1. Mycophenolate mofetil or cyclophosphamide for symptomatic ILD
  2. Nintedanib, a small molecule that inhibits several kinases linked to the pathogenesis of interstitial lung diseases (receptor tyrosine kinases and nonreceptor tyrosine kinases), recently received FDA approval for the treatment of ILD associated with systemic sclerosis
  3. Lung transplantation for patients with advanced pulmonary involvement
- Pulmonary hypertension:
  1. Oxygen
  2. Diuretics (with caution)
  3. Prostacyclins (epoprostenol, iloprost, treprostinil)
  4. Endothelin-1 receptor inhibitors (bosentan, ambrisentan)
  5. Phosphodiesterase 5 inhibitors (sildenafil, tadalafil)
  6. Table E9 summarizes approved therapies for treatment of pulmonary arterial hypertension
- Renal involvement:
  1. Angiotensin-converting enzyme inhibitors
  2. Dialysis
  3. Renal transplantation

TABLE 5 Autoantigens and Autoantibodies in Scleroderma

Autoantigen	Molecular Structure	Autoantibody Frequency
Scl-70	100-kD native and 70-kD degradation product; DNA topoisomerase I	75% in diffuse scleroderma; 20%-59% in all patients; 13% in CREST
Centromere	Proteins 17, 80, and 140 kD; localized at inner and outer kinetochore plates	57%-82% in CREST; 8% in diffuse form
RNA Pol I	RNA Pol I complex of subunit proteins, 210-211 kD	4%-30% in scleroderma; 13% in diffuse form
RNA Pol II	Transcripts mRNA	4%
RNA Pol III	Transcripts 5S rRNA, tRNA	23% in scleroderma; 45% in diffuse form; 6% in CREST
Fibrillarin	Protein 34 kD, component of U3 RNP particle	6%-8%; 5% in diffuse form; 10% in CREST
U1nRNP	Spliceosome complex	2%-5% in all patients; 24% in PM/scleroderma overlap
PM-Scl	Complex of 11 proteins, 110-120 kD	4%-11%; 24% in PM/scleroderma overlap
Ku	DNA-binding protein	1%-14% in scleroderma; 26%-55% in PM/scleroderma overlap
Th/To	Protein 40 kD, complexes with 7S and 8S RNAs	1%-13% in scleroderma; 1%-11% in diffuse form; 8%-19% in CREST; up to 3% in PM/scleroderma overlap
NOR-90	Protein 90 kD, human upstream binding factor, localized in nucleolus organizer region	Rare

CREST, Calcinosis, Raynaud phenomenon, esophageal dysfunction, sclerodactyly, and telangiectasia; *DNA,* deoxyribonucleic acid; *mRNA,* messenger RNA; *PM,* polymyositis; *RNA,* ribonucleic acid; *RNP,* ribonucleoprotein; *rRNA,* ribosomal RNA; *tRNA,* transfer RNA.
From McPherson RA, Pincus MR: *Henry's clinical diagnosis and management by laboratory methods*, ed 23, Philadelphia, 2017, Elsevier.

REFERRAL

Rheumatology consultation is indicated. Consider pulmonary, cardiology, or gastrointestinal consultations depending on organ involvement.

PEARLS & CONSIDERATIONS

COMMENTS

Autologous hematopoietic stem cell therapy (HSCT) has shown some benefit in patients with severe diffuse cutaneous systemic sclerosis, but there was greater treatment-related mortality and morbidity associated with HSCT.

FIG. E1 Sclerodactyly in a patient with systemic sclerosis. (From Hochberg MC, et al.: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

FIG. E2 Skin involvement in scleroderma is subdivided into "limited" and "diffuse" cutaneous forms. A, Sclerodactyly in limited cutaneous disease. **B,** Truncal changes in diffuse cutaneous disease. **C,** Inflammatory signs in early active skin disease. **D,** Finger contracture in the chronic fibrotic phase of skin involvement in scleroderma. (From Firestein GS, et al.: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

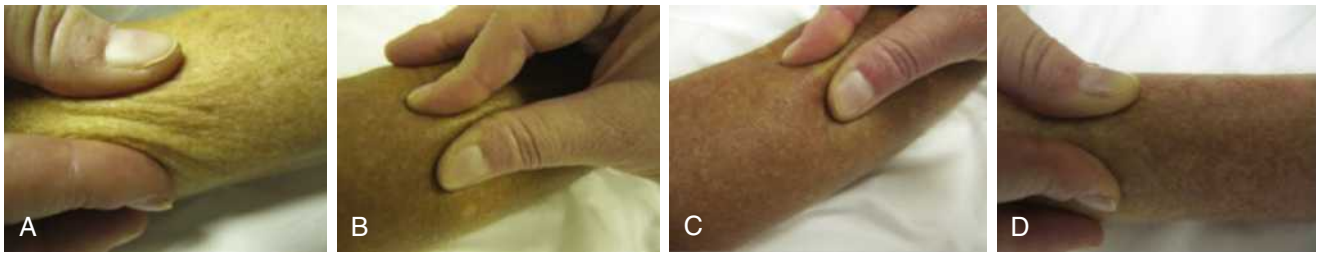

FIG.E3 Method used to semi-quantify skin thickness in scleroderma. The modified Rodnan skin score is obtained by clinical palpation of 17 different body areas (fingers, hands, forearms, upper arms, chest, abdomen, thighs, lower legs, and feet) and subjective averaging of the thickness of each specific site: 0 = normal **(A)**; 1 = mild **(B)**; 2 = moderate **(C)**; and 3 = severe **(D)**. The maximum score is 51. (From Firestein GS, et al.: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

FIG. E4 Oral manifestations. A, Perioral skin tightening with decreased oral aperture, furrowing around the lips, and dry membranes. **B,** Periodontal disease with regression of gum and loosening of teeth. **C** and **D,** Telangiectasias on lips and tongue. (From Firestein GS, et al.: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

TABLE E1 Overview of Musculoskeletal Complications of Systemic Sclerosis

Manifestation	Clinical Features	Serologic Associations
Contractures	Typical feature of dcSSc Associated with ARA positivity Palmar fibrosis	ARA, ATA, RF, ACPA
Tendonitis or tendon friction rubs	Overlap arthritis	ARA
Arthritis	May resemble RA in overlap Associated with RF positivity and ACPA positivity More with U1RNP reactivity Contributes to deformity and contractures May have Jaccoud pattern but with fixed deformity	U1RNP, ACPA, RF
Myositis	Minor elevation in CK common, especially in dcSSc Weakness and loss of muscle bulk Severe myositis less frequent Overlap syndromes with myositis most common Serologic associations include anti–PM-Scl, anti-U1RNP, anti-fibrillarin	U1RNP, PM-Scl, U3RNP
Acro-osteolysis	More common in environmentally triggered SSc Association with vasculopathy and Raynaud phenomenon Possible association with calcinosis	ACA, ATA

ACA, Anticentromere; *ACPA,* anti-cyclic citrullinated protein antibody; *ARA,* anti-RNA polymerase III antibody; *ATA,* antitopoisomerase; *CK,* creatine kinase; *dcSSc,* diffuse cutaneous systemic sclerosis; *PM-Scl,* anti-polymyositis scleroderma antibody; *RA,* rheumatoid arthritis; *RF,* rheumatoid factor; SSc, systemic sclerosis; *U1RNP,* anti-U1-ribonucleoprotein antibody; *U3RNP,* anti-U3-ribonucleoprotein antibody.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

TABLE E2 Patterns of Parenchymal Lung Involvement in Systemic Sclerosis

Classification	HRCT Appearance	Frequency (%)	Outcome	Treatment
NSIP	Homogeneous interstitial shadowing with traction bronchiectasis and predilection for bases and subpleural locations	50	Variable depending on extent of disease	Supportive Antireflux MMF or CYC RTX Experimental agents
UIP	Heterogeneous interstitial shadowing with architectural distortion, traction bronchiectasis, and cystic changes	15	Variable depending on extent of disease and may have worse outcome than NSIP but not as much as in IPF	Supportive Antireflux MMF or CYC RTX Experimental agents
OP	Patchy and asymmetric changes with homogeneous appearance and later patchy scarring	5	Potential for improvements and recovery if treated effectively	Steroids and anti-infective treatment MMF or CYC if associated with significant fibrosis
PF with emphysema	Interstitial fibrotic change that may have NSIP or UIP features and is associated with airspace enlargement and concurrent emphysematous change	10	Variable depending on extent and severity	Supportive Antireflux MMF or CYC RTX for fibrosis Manage airway disease according to severity and responsiveness
Pleuroparenchymal fibroelastosis	Interstitial fibrosis with additional pleural-based dense fibrosis and scarring extending to the upper zones	1	Progressive and difficult to treat with poor outcome	Supportive Antireflux MMF or CYC RTX for fibrosis
Aspiration pneumonia	Asymmetric changes often associated with esophageal dilatation; leaves patchy scarring	20	Potential for improvements and recovery if treated effectively; may be aggravated by immunosuppression	Vigorous antireflux and acid suppressive therapy Prophylactic antibiotics and prompt treatment of intercurrent infection

CYC, Cyclophosphamide; *IPF,* idiopathic pulmonary fibrosis; *MMF,* mycophenolate mofetil; *NSIP,* nonspecific interstitial pneumonia; *OP,* organizing pneumonia; *PF,* pulmonary fibrosis; *RTX,* rituximab; *UIP,* usual interstitial pneumonia.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

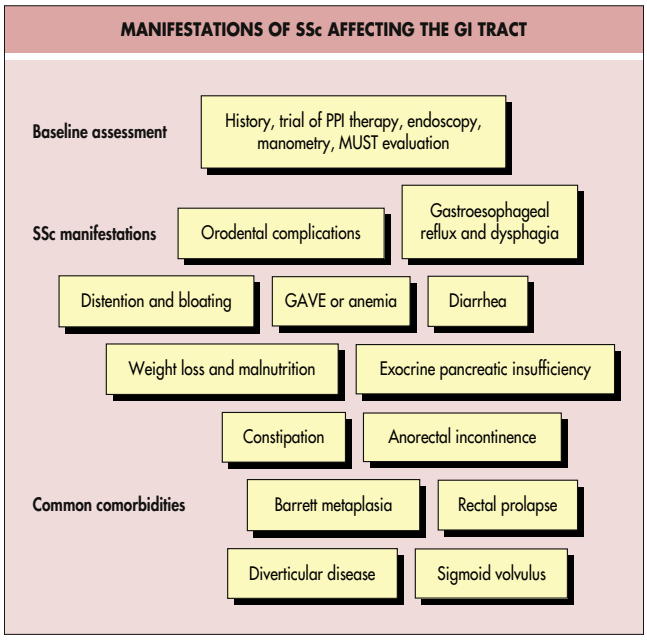

FIG. E5 Manifestations of systemic sclerosis within the gastrointestinal (GI) tract are frequent and require careful assessment. The major features are summarized for the upper, mid-, and lower GI tract along with important comorbidities that may need additional assessment and treatment. *GAVE,* Gastric antral vascular ectasia; *MUST,* Malnutrition Universal Screening Tool; *PPI,* proton pump inhibitor. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

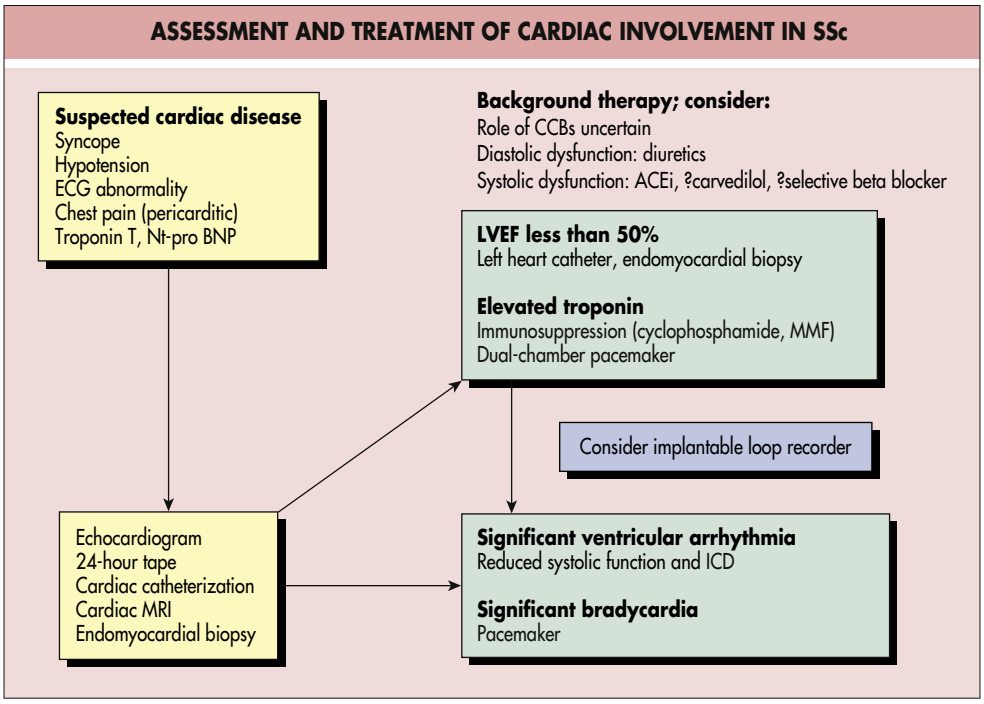

FIG. E6 Cardiac manifestations of systemic sclerosis (SSc) are common but can be challenging to diagnose and manage. This is because minor changes in rate or imaging may not be significant, and other manifestations can be unpredictable. Cardiac involvement should be investigated systematically, and hemodynamically significant disease may be treated as outlined in the figure. The use of loop recording reveal devices in cases with suspected sporadic significant arrhythmias may be considered to identify patients who may benefit from an implantable defibrillator (ICD). *ACEI,* Angiotensin-converting enzyme inhibitor; *CCB,* calcium channel blocker; *ECG,* electrocardiogram; *LVEF,* left ventricular ejection fraction; *MMF,* mycophenolate mofetil; *MRI,* magnetic resonance imaging; *Nt-pro BNP,* N-terminal pro b-type natriuretic peptide. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

TABLE E6 Vascular Therapies for Raynaud Phenomenon

Treatment	Examples	Comments	Reference	Grade*
Nondrug	Hand warmers, protective clothing	Universally helpful		
Nutritional	Evening primrose oil	Symptoms improve		
	Fish oil capsules	Symptoms improve only in primary Raynaud, not scleroderma		
	Antioxidant vitamins	Theoretical benefit but no controlled trial evidence		
Pharmacologic Agents for Raynaud Phenomenon				
Calcium channel blockers	Nifedipine, amlodipine, diltiazem	Variable and differential response to different agents; slow titration of dose reduces the severity of adverse effects	1	A
Angiotensin-converting enzyme inhibitors (quinapril)		No evidence of effectiveness	2	A
Angiotensin receptor blockers	Losartan	Effective in clinical trial but limited effectiveness in practice	3	A
Selective serotonin reuptake inhibitor	Fluoxetine	Readily available; clinically less effective but fewer adverse vasodilatory effects than calcium channel blockers	4	A
Topical nitrates	Nitroglycerin patch MQX-503, topical nitroglycerin	Long-acting patch helpful but many side effects; multiple studies new agent with significant results but not approved by FDA	5, 6	A
Treatment for Ulcers				
Phosphodiesterase inhibitors	Sildenafil, tadalafil	Clinical trials show improvement in Raynaud manifestations and ulcer healing	7, 8	A
Parenteral vasodilators	Iloprost, prostaglandin E_1, treprostinil	Effective in healing ulcers and reducing severity and frequency of Raynaud attacks; expensive with limited long-term benefit (not available in U.S.)	9	C
Endothelin receptor antagonists	Bosentan	Clinical trials show decrease in new ulcers but no effect on healing (approved for prevention of ulcers in Europe but not in U.S.)	10, 11	A
Statins		Single study showing decreased occurrence of ulcers	12	A
Local management of ulcers		Wound-healing techniques, topical antibiotics, soaking, occlusion, debridement; systemic antibiotics as necessary; adequate analgesia (including narcotics if necessary)		
Surgical Procedures				
Radical microarteriolysis, digital sympathectomy		Division of adventitia of digital arteries; sometimes termed *digital sympathectomy.* Useful treatment for individual critically ischemic digits; experimental treatment showing improved pain and mobility; phase 3 trial of adipose-derived stromal injections ongoing	13	B
Autologous adipose–derived stromal injections and fat grafting			14-16	B
Botulinum toxin A (Botox) "sympathectomy"		Small studies promising but clinical trials needed	17	C
Debridement, amputation		Autoamputation is best to allow maximum preservation of healthy tissue. Surgery should be conservative and reserved for cases of infection or intractable pain.		

*Findings of studies include these types of evidence:
Level A: Randomized controlled clinical trial, cohort study.
Level B: Retrospective cohort, exploratory cohort, outcomes research, case-control study; or extrapolations from level A studies.
Level C: Case-series study or extrapolations from level B studies.
Level D: Expert opinion without explicit critical appraisal; or based on physiology, bench research, or first principles.
FDA, Food and Drug Administration.

TABLE E7 Evidence-Based Review of Immunomodulatory and Antifibrotic Strategies for Disease-modifying Treatment of Systemic Sclerosis Skin Disease

Agent	Clinical Trial Data	Reference	Grade*
Immunomodulatory Agents			
Methotrexate	Placebo-controlled trial, 30 patients; significant improvement in skin score	18	A
	Larger North American study; inconclusive results	19	A
Mycophenolate	Favorable outcomes in skin, lung, and survival rate in uncontrolled trials and observational cohorts	20, 21	B
Rituximab	Small, open, randomized trial showed favorable skin and lung outcomes, but prospective open study found no effect on skin	22, 23	B
	Observational cohort study found positive effect on joints, skin, and PFTs	24	A
Immunoablation	Observational experience marked improvement in skin	25	B
	Small, short-term study comparing stem cell transplantation with high-dose intravenous cyclophosphamide (Cytoxan); very favorable results	26	A
	ASTIS controlled trial with improved skin and survival	27	A
Cyclosporine	Open study, 10 patients; improvement in skin score	28	C
Intravenous immunoglobulin	Improved skin and joint status in open study	29	C
Extracorporeal photopheresis	First study suggested benefit but later evaluation equivocal	30	A
Oral induction of tolerance to type I collagen	Favorable pilot data; trial results positive for late-stage disease	31	A
Anti–IL-6, tocilizumab	Phase 2 trial with improved skin and less loss of lung function	32	A
Antifibrotic Agents			
D-Penicillamine	Uncontrolled studies with positive effects but controlled trial without evidence of response	33	B
		34	A
Minocycline	Small, open study with cured patients but larger uncontrolled study showing no effect	35	C
		36	B
Tyrosine kinase	Variable effects in several uncontrolled inhibitor trials showing increased toxicity and a controlled trial that was negative	37, 38, 39	B A

*Findings of studies include these types of evidence:
Level A: Randomized controlled clinical trial, cohort study.
Level B: Retrospective cohort, exploratory cohort, outcomes research, case-control study; or extrapolations from level A studies
Level C: Case-series study or extrapolations from level B studies
Level D: Expert opinion without explicit critical appraisal; or based on physiology, bench research, or first principles

TABLE E8 Treatment of Gastrointestinal Tract Complications in Systemic Sclerosis

Site	Disorder	Symptom	Investigation	Treatment
Mouth	Tight skin	Cosmetic	None	Facial exercises
	Dental caries	Toothache	Dental radiograph	Dental treatment
	Sicca syndrome	Dry mouth	Salivary gland biopsy	Artificial saliva
Esophagus	Dysmotility or esophageal spasm	Dysphagia	Barium swallow	PPIs
	Reflux esophagitis	Heartburn	Esophageal scintigraphy	Minimize NSAID and CCB use
	Stricture	Dysphagia	Manometry, endoscopy	Elevate head of bed, avoid late meals
Stomach	Gastroparesis	Anorexia, nausea, early satiety	Scintigraphy	Erythromycin (as motility agent), metoclopramide, domperidone, PPIs
	NSAID-related ulcer	Pain	Endoscopy, barium UGI	PPIs
	Gastric antral vascular ectasia or watermelon stomach	Severe anemia, silent blood loss	Endoscopy	Laser coagulation
Small bowel	Hypomotility	Weight loss	Barium follow-through	Rotational antibiotics, metronidazole, ciprofloxacin, rifaximin, octreotide (low dose) for severe disease; TPN in rare cases
	Stasis	Postprandial bloating	^{14}C glycocholate or hydrogen breath tests	
	Bacterial overgrowth	Malabsorption	Breath tests	Domperidone, metoclopramide, rotational antibiotics, metronidazole, ciprofloxacin, rifaximin
	NSAID enteropathy	Steatorrhea	Jejunal aspiration	
	Pseudo-obstruction	Abdominal pain	Fecal microscopy	Oral nutritional supplements
		Distention	Plain abdominal radiography	Parenteral nutritional support
	Pneumatosis intestinalis	Diarrhea with blood, benign pneumoperitoneum	Plain abdominal radiography	Conservative management
Large bowel	Hypomotility	Alternating constipation and diarrhea	Barium enema, CT of abdomen	Dietary manipulation, stool expanders for constipation, loperamide for diarrhea
	Colonic pseudodiverticula	Rare perforation	Barium enema, CT of abdomen	Resection as a last resort
	Pseudo-obstruction	Abdominal pain, distention	Plain abdominal radiography	Conservative management
Anus	Sphincter involvement	Fecal incontinence	Rectal manometry	Kegel exercises, protective measures, sacral nerve stimulation

CCB, Calcium channel blocker; *CT,* computed tomography; *NSAID,* nonsteroidal antiinflammatory drug; *PPI,* proton pump inhibitor; *TPN,* total parenteral nutrition.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

TABLE E9 Approved Therapies for Treatment of Pulmonary Arterial Hypertension

Class of Drug	Drug	Route of Administration	Main Adverse Effects	Comments
Endothelin receptor antagonists	Bosentan	Oral twice a day	LFT abnormalities in up to 10% (bosentan); reduces oral anticoagulant efficacy (bosentan); potentially teratogenic; fluid retention and anemia	Nonselective ET_A and ET_B blockade
	Ambrisentan	Oral daily dose	Potentially teratogenic; fluid retention and anemia	Partially selective ERA with specificity for ET_A
	Macitentan	Oral daily dose	Potentially teratogenic; fluid retention and anemia	Nonselective ET_A and ET_B blockade (more tissue-specific)
Nitric oxide stimulation	Sildenafil, PDE5 inhibitor	Oral: 3 times a day	Headache, visual disturbance, epistaxis; generally well tolerated	Different formulation licensed for erectile dysfunction
	Tadalafil, PDE 5 inhibitor	Oral: Once daily	Headache, visual disturbance, epistaxis	Generally well tolerated; longer duration of action than sildenafil
	Riociguat, guanylin cyclase stimulator	Oral: Twice a day	Headache, hypotension, bleeding	Cannot be used with PDE5 inhibitors reserved for severe disease
Prostacyclin analogues	Epoprostenol	Continuous IV infusion	Headaches, muscle cramps, diarrhea; severe worsening if infusion interrupted; sepsis and other risks from IV administration	Reserved for severe disease; Side effects for all prostacyclins are similar and often limit dose
	Treprostinil	SC or IV infusion Nebulized inhaled: 4 times a day Oral: 3 times a day	Headaches, muscle cramps, diarrhea; worsening if infusion interrupted but less immediate than with epoprostenol; sepsis and other risks from IV administration; severe local site pain from SC infusion	
	Iloprost	Nebulized inhaled: 6-9 times a day	Headaches, muscle cramps, diarrhea	Inhaled drug PAH
	Beraprost	Oral: 60 μg a day	Headaches, muscle cramps, diarrhea	Licensed only in Japan
	Selexipag, prostacyclin receptor stimulator	Oral: Twice a day	Headaches, muscle cramps, diarrhea	Recently approved; will need to see if as effective as IV drugs

ERA, Endothelin receptor antagonist; *ET_A,* endothelin receptor type A; *ET_B,* endothelin receptor type B; *IV,* intravenous; *LFT,* liver function test; *PAH,* pulmonary arterial hypertension; *PDE5,* phosphodiesterase type 5; *SC,* subcutaneous.

From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

BASIC INFORMATION

DEFINITION

Scoliosis is a three-dimensional spine deformity characterized by lateral and rotational curvature of the spine. The two main types are adolescent idiopathic scoliosis (AIS) and adult degenerative scoliosis (ADS), which are distinguished by age of onset. Scoliosis may be classified as either structural (fixed, nonflexible) or nonstructural (flexible, correctable, and secondary to nonspinal pathology). Scoliosis is often detected on physical examination (Adams forward bend test) and confirmed radiographically.

ICD-10CM CODES	
M41	Scoliosis
M41.0	Infantile idiopathic scoliosis
M41.1	Juvenile idiopathic scoliosis
M41.20	Other idiopathic scoliosis, site unspecified
M41.3	Thoracogenic scoliosis
M41.40	Neuromuscular scoliosis, site unspecified
M41.80	Other forms of scoliosis, site unspecified
Q67.5	Congenital deformity of spine

EPIDEMIOLOGY & DEMOGRAPHICS (IDIOPATHIC FORM)

PREDOMINANT SEX: The incidence of AIS is similar in males and females; however, females have up to a tenfold greater risk of curve progression. Females are roughly seven times as likely to require orthopedic surgical intervention for idiopathic scoliosis. ADS has an equal gender distribution.
PREVALENCE: 1.5% to 3% of adolescents
PREDOMINANT AGE:
- Onset variable
- Most curves found in adolescents (age ≥11 yr)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typical presentation involves postural complaints rather than pain or neurologic symptoms.
- Record patient age (in yrs plus mos) and height.
- Perform neurologic examination to rule out neuromuscular disease.
- Inspect the shoulders and iliac crests to determine if they are level.
- Palpate the spinous processes to determine their alignment.
- Have the patient bend forward at the waist to approximately 45 degrees with the arms hanging free (Adams position); observe from the back to detect whether one side of the back appears higher than the other (Fig. 1).
- May repeat forward bending test in a sitting position to eliminate leg length inequality.

ETIOLOGY

- 90% unknown, referred to as *idiopathic* (genetic)
- Congenital spine deformity
- Neuromuscular disease
- Leg-length inequality
- Local inflammation or infection
- Acute pain (disk disease)
- Chronic degenerative disk disease with asymmetric disk narrowing

Curves of an idiopathic nature or those accompanying congenital deformity or neuromuscular disease are associated with structural changes. The nonstructural types (leg-length discrepancy, muscle spasm, inflammation, or acute pain) disappear when the offending disorder is corrected.

DIAGNOSIS

WORKUP

- Curvatures associated with congenital spine abnormalities, neuromuscular disease, and other less common forms of scoliosis can usually be identified by history or associated radiographic or physical findings.
- The diagnosis of scoliosis is suspected on the basis of physical examination and confirmed by radiography performed while the patient is in a standing position. Physical examination with the Adams forward bend test and scoliometer measurement can identify scoliosis, and the radiologic testing for Cobb angle measurement can confirm the diagnosis. The Cobb angle is measured on a thoraco-lumbar radiograph and is defined as the intersecting angle between lines drawn parallel to the endplates of the two vertebrae with the greatest amount of tilt. The Risser grade measures ossification of the iliac apophysis. It consists of five grades ranging from 25% ossification in grade 1 to full ossification of the apophysis in grade 5. Lower Risser scores are associated with higher spinal growth potential. Patients with Risser scores of 0 or 1 are at greatest risk of scoliosis curve progression. Scoliosis screening is described in Fig. 2.

IMAGING STUDIES

- PA, lateral, and side-bending radiographs of the entire spine and pelvis.
- There is high potential for repeated radiation exposure in adolescents evaluated for scoliosis. Use breast and gonadal shielding whenever possible. If you are referring to a specialist that will be unable to view the images obtained, instruct the patient's family to bring a printed copy to their visit.
- Diagnosis of idiopathic scoliosis is confirmed by a Cobb angle greater than 10 degrees as measured on a radiograph.
- Severity of the curve is measured in degrees, usually by the Cobb method (Fig. 3).
- MRI is usually not indicated unless there is pain, neurologic deficit, or a left thoracic curve (which is often associated with an underlying spinal disorder).

TREATMENT

ACUTE GENERAL Rx

- Treatment or correction of cause if curve is nonstructural
- Early detection is key in treating genetic (idiopathic) curve
- Regular observation for curves <20 degrees
- If no curve progression, repeat imaging may be limited to once per yr
- Bracing for idiopathic curves of 25 to 45 degrees in patients with an immature skeleton (Risser score 0 to 2) to prevent progression
- Surgery (Fig. E4) for idiopathic curves >45 degrees in patients with an immature skeleton

DISPOSITION

- The larger the curve at detection, the greater the chance of progression.
- Progression is more common in young children who are beginning their growth spurt.
- Curves in females are more likely to progress.
- Curves <20 degrees will improve spontaneously >50% of the time.
- Failure to diagnose and treat these curves may allow progressive deformity, pain, and cardiopulmonary compromise to develop.
- Spinal deformities >50 degrees in adults may progress and eventually become painful or compromise pulmonary function.
- There is no difference in the rate of back pain in the general population and patients with adolescent idiopathic scoliosis.

REFERRAL

Refer for orthopedic consultation if structural curve >20 degrees is present or if structural curve <20 degrees progresses 5 degrees or more upon follow-up evaluation.

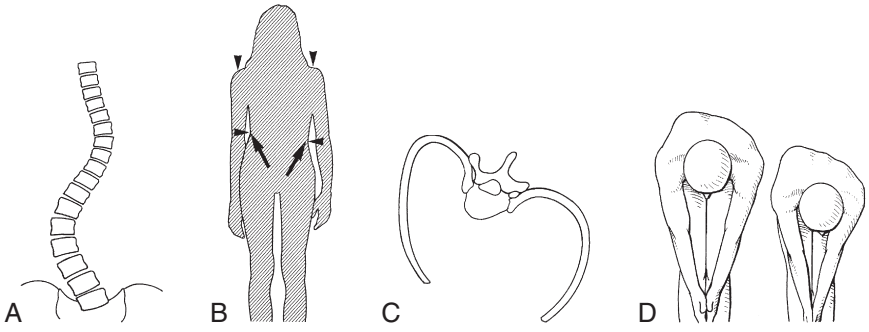

FIG. 1 Structural changes in idiopathic scoliosis. A, As curvature increases, alterations in body configuration develop in both the primary and compensatory curve regions. **B,** Asymmetries of shoulder height, waistline, and the elbow-to-flank distance are common findings. **C,** Vertebral rotation and associated posterior displacement of the ribs on the convex side of the curve are responsible for the characteristic deformity of the chest wall in scoliosis patients. **D,** In the school screening examination for scoliosis, the patient bends forward at the waist. Rib asymmetry of even a small degree is obvious.

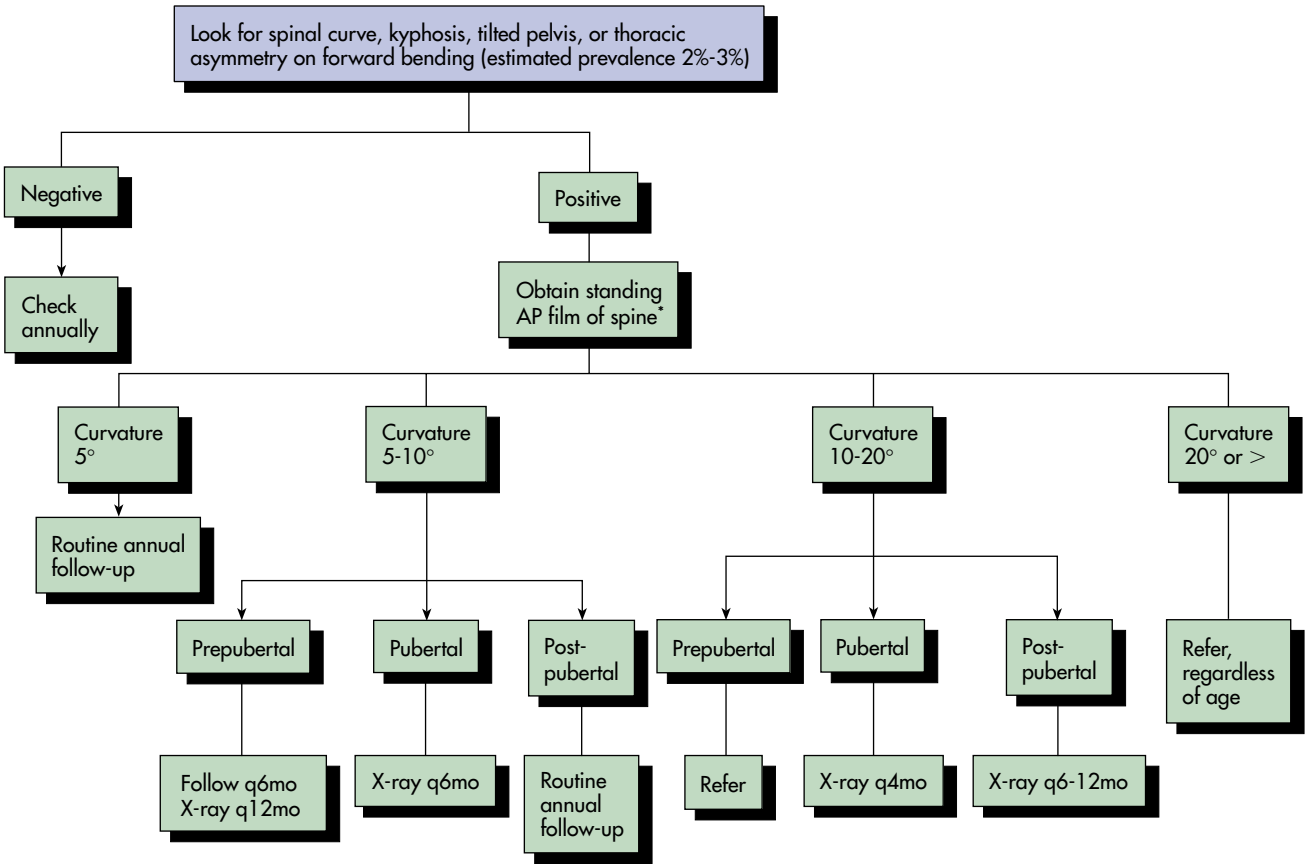

*Cobb method of angle measurement.

1. Find the lowest vertebra whose bottom tilts toward concavity of curve.
2. Erect a perpendicular line from extension of bottom surface.
3. Find highest vertebra as in #1 and erect perpendicular from extension of top surface.
4. Measure intersecting angle = angle of scoliosis.

FIG. 2 Scoliosis screening and follow-up. *AP,* Anteroposterior.

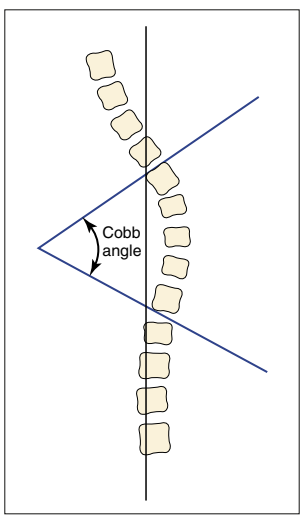

FIG. 3 Cobb angle. This is measured using the superior and inferior end plates of the most tilted vertebrae at the end of each curve. (From Tschudy MM, Arcara KM: *The Harriet Lane handbook,* ed 19, Philadelphia, 2012, Mosby.)

PEARLS & CONSIDERATIONS

COMMENTS

- Congenital scoliosis has a high incidence of cardiac and urinary tract abnormalities.
- Bracing is not intended to completely straighten the idiopathic curve. It may improve the curvature, but is mainly used to stabilize and prevent progression.
- The initial Cobb angle magnitude (≥25 degrees) is the most important predictor of long-term curve progression.

Scombroid Poisoning

BASIC INFORMATION

DEFINITION

Foodborne illness from improperly stored fish causing histamine toxicity when consumed, mimicking a type I hypersensitivity reaction

SYNONYMS

Scombroid fish poisoning

ICD-10CM CODES

T61.11 Scombroid fish poisoning, accidental
T61.12 Scombroid fish poisoning, intentional
T61.13 Scombroid fish poisoning, assault
T61.14 Scombroid fish poisoning, undetermined

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: According to the CDC's Foodborne Disease Outbreak surveillance system, data collected from U.S and Puerto Rico show the following:

- Between 1998 and 2008, there were 333 outbreaks and 1383 patient cases, no mortalities.
- Between 2009 and 2015, there were 101 total outbreak cases (95 were confirmed outbreak cases); 299 total patient cases (280 of these were confirmed individual patient cases); and 2 hospitalizations, no mortalities.

PEAK INCIDENCE: Summer

RISK FACTORS: Improperly stored fish at temperatures >4° C or >40° F

- Risk factors for more severe reaction
  1. Immunocompromised
  2. Patients with preexisting chronic pulmonary conditions
  3. Medications that inhibit metabolism of histamine
  4. Chronic diseases impairing normal cardiac response to hypotension

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typically within 30 min to 1 hour after ingestion, patients will experience symptoms of overwhelming levels of histamine that include:
  1. Metallic or peppery taste
  2. Cutaneous flushing
  3. Urticarial rash
  4. Perioral burning or edema
  5. Tachycardia/palpitations
  6. Dizziness
  7. Headache
  8. GI symptoms: Abdominal pain, nausea, vomiting, diarrhea
  9. Hypotension
- Rarer symptoms
  1. Bronchospasm
  2. Cardiac arrhythmias
  3. Shock

ETIOLOGY

There are certain types of fish whose flesh naturally has high levels of histidine. When they are not stored properly, bacteria (generally gram-negative Enterobacteriaceae) can grow and metabolize histidine into histamine. Once histamine is present, cooking, freezing, smoking will NOT destabilize it. Extent of poisoning is related to the quantity of histamine ingested, which is dependent on the growth of bacteria producing histamine and the amount of fish ingested.

Fish known to cause scombroid poisoning include:

- Scombridae family
  1. Tuna
  2. Mackerel
  3. Bonito
- Other examples
  1. Mahi-mahi
  2. Anchovies
  3. Sardines
  4. Albacore
  5. Marlin
  6. Herring
- Cheese
  1. Most notably, Swiss cheese

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Allergic reaction/anaphylaxis
- Asthma exacerbation
- Serum sickness
- Angioedema
- Ciguatera poisoning
- Table 1 summarizes marine biotoxins

WORKUP

- Unnecessary for diagnosis, however can obtain:
  1. Plasma levels of histamine
  2. Urine levels of histamine metabolites
  3. Plasma levels of tryptase: Should be negative in scombroid cases

LABORATORY TESTS

Not generally indicated unless there is a suspicion of intentional overdose

IMAGING STUDIES

Generally not indicated

TREATMENT

- Supportive care
- Antihistamines (PO if patient can tolerate)
  1. H_1 blocker: Benadryl
  2. H_2 blocker: Ranitidine, cimetidine, famotidine
  3. Can have patients take H_1/H_2 blockers scheduled after initial symptoms resolve to prevent recurrence
- If patient becomes anaphylactic, may need crystalloids, steroids, and epinephrine
- Hypotensive patients requiring fluids or epinephrine should be observed as an admit

NONPHARMACOLOGIC THERAPY

Fluids, no known benefit of crystalloid type

ACUTE GENERAL Rx

H_1 and H_2 blocker (PO or IV)

DISPOSITION

- Supportive care is normally sufficient. Symptoms should resolve in 1 to 2 days, and most patients can be discharged home if they have no airway compromise or hypotension during their stay and are observed to be improving. There is no standard of care for length of observation.
- In cases of patients with preexisting illnesses or medications that predispose them to a more severe manifestation of the illness:
  1. The duration of illness may be prolonged.
  2. May need admission for observation until toxicity has resolved.

REFERRAL

The local health department should be notified when a scombroid case is suspected.

PEARLS & CONSIDERATIONS

COMMENTS

This is not a true allergy. Histamine already is present in the fish or cheese consumed, as opposed to a Type I hypersensitivity reaction, in which the patient's immune system reacts to the fish's antigens and generates histamine. In the case of scombroid, only the histamine consumed is part of the reaction.

PREVENTION

Store fish immediately after it is caught to prevent bacterial growth and conversion of histidine in dark meat into histamine (<44° C or <40° F). In some instances, fish is caught and stored improperly long before the market or restaurant takes possession of it. When histamine levels are high, no cooking, smoking, or boiling will eradicate it. Fish with high histamine levels may not taste bad or have any distinguishing features until consumed. All persons consuming contaminated fish should react to the stored histamine, so an isolated case in which several people share a meal of the same fish should raise suspicion of an alternate diagnosis.

Seasonal Affective Disorder (PTG)

BASIC INFORMATION

DEFINITION

Recurrent depressive episodes during autumn and winter alternating with nondepressive episodes during spring and summer (less frequently, recurring depressive episodes during spring and summer, alternate with nondepressive episodes during autumn and winter). Patients with seasonal affective disorder (SAD) have experienced two episodes of major depression in the past 2 yr that demonstrate the temporal seasonal relations and have had no nonseasonal episodes over this period. Furthermore, seasonal depressive episodes substantially outnumber nonseasonal depressive episodes throughout the individual's lifetime.

SYNONYMS

SAD
Seasonal depression
Winter depression
Wintertime blues

ICD-10CM CODES

F33	Recurrent depressive disorder
F33.0	Recurrent depressive disorder, current episode, mild
F33.1	Recurrent depressive disorder, moderate
F33.2	Recurrent depressive disorder, severe without psychotic symptoms
F33.3	Recurrent depressive disorder, severe with psychotic symptoms
F33.4	Recurrent depressive disorder, currently in remission
F33.9	Recurrent depressive disorder, unspecified

DSM-5 CODE

There is no DSM-5 code for seasonal affective. It is now categorized as a specifier under major depression.

EPIDEMIOLOGY & DEMOGRAPHICS

- Climate, genetic vulnerability, and psychological and sociocultural factors all play a role. The risk of seasonal mood swings is clearly associated with northern latitudes. The prevalence of SAD is estimated to be 0.5% to 1.5% in northern European populations, but up to 10% to 20% of these populations report milder, recurrent episodes consistent with subsyndromal SAD. In the U.S., it is estimated that about 5% of the population experiences SAD.
- As with other depressive disorders, women are affected disproportionately.
- Younger age, as well as greater familiarity with SAD, is associated with increased prevalence.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The symptoms of SAD can be identical to those of other depressive episodes, but tend to include features associated with atypical major depression, including low energy, oversleeping, irritability, weight gain, and overeating. The onset of neurovegetative symptoms often precedes the onset of cognitive and affective symptoms.
- Average duration is 5 mo, generally beginning in November.

ETIOLOGY

- Explanations focus on diathesis-stress models. An interaction between biologic and cognitive-affective factors appears to contribute to SAD. Retinal sensitivity anomalies and emotional reactivity to light stimuli, genetic variables predisposing to seasonal shift in sleep patterns in response to shorter photoperiod, circadian rhythm disturbance, and irregularities in melatonin, serotonin, and melatonin-serotonin interaction have been identified as potential risk factors. Shorter photoperiod and decrease in sunlight are hypothesized to be the triggers.
- Several neurotransmitters implicated, including dopamine, serotonin, and norepinephrine.
- Cognitive risk factors include elevated rumination and negative cognitions related to the winter season and its impact on one's mood.
- Low activity and exercise levels, which are also implicated in nonseasonal depression, have been shown in some studies to characterize SAD.
- Patients with nonseasonal depression and/or anxiety may also show symptom exacerbations during the winter mos.

DIAGNOSIS

Diagnostic workup similar to that for major depression

DIFFERENTIAL DIAGNOSIS

- Major depressive disorder
- Minor depression or adjustment disorder
- Bipolar affective disorder
- Evaluate for substance use (especially alcohol)
- Medical illness or medications that may contribute to depression (e.g., endocrine disorders, neurologic disease)

WORKUP

- As with major depression, consider medical etiologies and rule out as indicated by the presenting signs and symptoms. Consider endocrine evaluation, especially thyroid function; sleep studies and a toxicology screen might be considered.
- Structured Interview Guide for the Hamilton Depression Rating Scale–Seasonal Affective Disorders Version (SIGH-SAD) used in research settings.
- In patients with major depressive disorder treated longitudinally, the routine use of depression scales to monitor outcome can help identify seasonal fluctuations of symptoms. Self-report scales to assess seasonal fluctuations in depressive symptoms have been developed but are not routinely used in clinical settings.

LABORATORY TESTS

As directed by presenting symptoms

IMAGING STUDIES

Generally not indicated

TREATMENT

NONPHARMACOLOGIC THERAPY

- Phototherapy presupposes that artificial light at a similar strength to natural sunlight will prevent the biologic changes that mediate SAD.
- Many studies have demonstrated efficacy of light therapy in individuals with SAD. Recent studies indicate that light therapy may also be efficacious with various subtypes of depression, including both melancholic and atypical, and for individuals with nonseasonal depression, though more research is needed. Transcranial photobiomodulation approaches are now under study.
- Light therapy may be used as a first-line treatment; choice of light therapy versus medication or psychotherapy depends on various factors, however, including severity of symptoms and suicidality, prior response to medication or light therapy, feasibility, and patient preference, and patient treatment expectations may also play a role.
- Some studies showing retinal sensitivity and neurotransmitter (e.g., serotonin) anomalies in SAD normalize following phototherapy, but more research is needed.
- Phototherapy tends to use 2500 to 10,000 lux delivered by a commercial light box or a portable head-mounted unit. Phototherapy is recommended to begin within 2 wk of the start of symptoms and continue through the winter mos. Patients are instructed to sit ~18 in from the light box for 30 min up to several hours once or twice per day for a minimum of 1 wk. Most studies have examined broad-wavelength (bright white) light: Studies are currently underway to examine potential advantages of short-wavelength (blue) light, though more research is needed.
- A recent meta-analysis demonstrated efficacy of high-density negative ions in reducing depressive severity, although further research is needed to determine whether efficacy is comparable to light therapy.
- Growing research demonstrates the efficacy of cognitive-behavioral therapy tailored specifically for SAD, either alone or with possible additive effects to light therapy. Cognitive behavioral therapy (CBT) for SAD appears to operate through distinct mechanisms than light therapy (e.g., reducing rumination and negative SAD-related cognitions). Patients with elevated cognitive symptoms of depression may benefit from CBT or combined CBT with light therapy over light therapy alone, and a recent study found a lower recurrence rate following CBT compared with light therapy, but further research is needed.

PHARMACOLOGIC THERAPY

Bupropion is effective in preventing recurrence.

ACUTE GENERAL Rx

Necessary if patient is suicidal

CHRONIC Rx

- Growing support for use of selective serotonin reuptake inhibitors (SSRIs) for SAD (e.g., fluoxetine, sertraline), although more research is needed.
- Preliminary studies demonstrated efficacy of novel antidepressants that act on melatonin (i.e., agomelatine), but further research is needed.

DISPOSITION

Psychiatric referral may be helpful to confirm diagnosis. Recommended for high-risk and suicidal patients.

REFERRAL

For active suicidal ideation, psychosis, symptoms suggestive of bipolar disorder

PEARLS & CONSIDERATIONS

Patients with SAD may present with a complaint of overeating, particularly food high in carbohydrates.

RELATED CONTENT

Seborrheic Dermatitis (SD) PTG

BASIC INFORMATION

DEFINITION

Seborrheic dermatitis (SD) is a common, inflammatory skin condition characterized by a mild to severe rash with scaling and erythema that occurs in areas of the skin rich in sebaceous glands.

SYNONYMS

SD
Dandruff
Cradle cap (Fig. E1)
Sebopsoriasis
Seborrheic eczema
Pityriasis capitis
Seborrhea

ICD-10CM CODES
L21.9 Seborrheic dermatitis, unspecified
L21.1 Seborrheic infantile dermatitis
L21.8 Other seborrheic dermatitis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Affects 3% to 5% of otherwise healthy adults; increases to 34% to 83% in immunocompromised patients
PREDOMINANT SEX AND AGE: Can occur from infancy through old age, with peak incidence in adolescents and young adults and increasing again after age 50 yr. More common in men than women.
RISK FACTORS: More common in patients with HIV/AIDS, Parkinson disease, other neurologic disorders, mood disorders, chronic alcoholic pancreatitis, hepatitis, cancer, and genetic disorders (e.g., Down syndrome). Recent evidence linking obesity and metabolic syndrome with an increased occurrence of SD. Occurs more often during winter season and during periods of increased stress.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Mild, greasy scaling of the scalp and nasolabial folds (Fig. E2); postauricular skin, beard area, eyebrows, trunk, and sometimes the central face. Blepharitis, otitis externa, and coexisting acne vulgaris or pityriasis may also be present. Itching and stinging of lesions can occur. Increased occurrence during times of stress or sleep deprivation.
- The scale often has a yellow, greasy appearance.

ETIOLOGY

- Fungal infections of the *Malassezia* species have been associated with SD, and the skin changes are thought to result from an inflammatory response to *Malassezia* yeast.
- Altered immune function may play a role. Patients with SD may show upregulation of interferon (IFN)-α, expressed interleukin-6 (IL-6), expressed IL-1β, and IL-4.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis
- Candidiasis
- Dermatophytosis
- Impetigo
- Psoriasis
- Rosacea
- Systemic lupus erythematosus
- Tinea infection
- Contact dermatitis
- Nummular dermatitis

WORKUP

- Diagnosis usually based on clinical identification of lesions (distribution and appearance).
- Skin biopsies can be performed, if warranted, to distinguish SD from similar disorders.

LABORATORY TESTS

- Microscopic examination with special stains can be used to determine whether yeast cells are present in keratinocytes.
- Biopsy can demonstrate parakeratosis in the epidermis, plugged follicular ostia, and spongiosis.
- HIV testing.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Patient education that SD is a chronic condition and treatment is aimed at resolving lesions but does not prevent recurrence.
- General recommendations: Wash skin regularly, soften and remove scales, and apply moisturizing emollients after washing.
- Scale removal can be accomplished through the application of mineral or olive oil and removed with a comb or brush after 1 hr.

ACUTE GENERAL Rx

- Antifungals (e.g., Nizoral, selenium sulfide, ketoconazole [the most evidence for effectiveness among antifungals], ciclopirox, fluconazole). Considered first-line therapy. Shampoos should be kept on the skin for 5 min before washing off.
- Reserve oral antifungal therapy for patients with widespread SD, or SD that is refractory to topical therapy.
- Topical steroids: Can be in the form of shampoos, creams, or ointments. Can be used alone or in more severe SD with antifungals. Desonide and mometasone display the lowest recurrence rates and highest clearance. Avoid prolonged use due to side effects.
- Calcineurin inhibitors (e.g., tacrolimus ointment, pimecrolimus cream): Good when face and ears are affected. Limit use due to potential side effects. Can be used in combination with topical nonsteroidal antiinflammatory agents
- Keratolytics (e.g. coal tar, salicylic acid, zinc pyrithione).
- Treatment of any secondary bacterial infection with oral antibiotics.

CHRONIC Rx

Recalcitrant SD: Topical azole combined with desonide regimen (limit use to 2 wk), pimecrolimus cream

COMPLEMENTARY & ALTERNATIVE MEDICINE

Borage and tea tree oil (melaleuca oil)
Crude honey
Aloe vera

REFERRAL

Consider referral to dermatology for recalcitrant cases or uncertain diagnosis.

PEARLS & CONSIDERATIONS

- Use a combination of topical steroids and antifungal cream for severe SD.
- Limit use of steroids to 2-wk course of treatment due to risk of cutaneous atrophy and telangiectasias.
- SD of the scalp can be treated with an antifungal (e.g., 2% ketoconazole) or keratolytic shampoo. Limit use of antifungal shampoos to twice a wk to prevent drying of the scalp. Alternate the use of antifungal shampoos with a moisturizing shampoo.
- In patients with widespread SD, consider testing for HIV infection. In patients with HIV/AIDS, the severity of seborrheic dermatitis is inversely correlated with the CDs counts.

BASIC INFORMATION

DEFINITION

Tonic clonic seizures are characterized by sudden loss of consciousness, muscle contraction (tonic phase), followed by rhythmic jerking activity (clonic phase).

SYNONYMS

Bilateral tonic-clonic seizures
Convulsive seizures
Grand mal seizures
Generalized tonic clonic seizures

ICD-10CM CODES
G40.6 Grand mal seizures, unspecified
G41.0 Grand mal status epilepticus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Thirty to fifty cases per 100,000 person-yr (epilepsy incidence)
PEAK INCIDENCE: Not applicable
PREVALENCE: Five to eight cases/1,000 persons (epilepsy incidence)
PREDOMINANT SEX AND AGE: No gender preference

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with tonic clonic seizures usually have normal physical and neurologic examinations.
- During the seizures, the patients are unresponsive and can have violent postures with severe repetitive muscle contractions (Fig. 1).
- After the seizure, the patients are usually lethargic and confused.
- Tonic clonic seizures are associated with injuries, bladder incontinence, and tongue biting.
- Any warning or aura before onset of the seizure or focal postictal weakness (Todd paralysis) may point toward a focal neurologic lesion.

ETIOLOGY

- Seizures are a cardinal sign of cortical neurologic injury. Generalized seizures include both hemispheres of the brain at onset. However, seizures can start focally and then quickly generalize across both hemispheres of the brain and be almost identical to primary generalized seizures. Any warning or aura symptoms before the generalized seizure starts would point to a focal onset.
- The etiology of seizures can be genetic or due to an acquired injury to the brain.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Convulsive syncope
- Psychogenic nonepileptic spells, conversion disorder, somatic symptom disorder, dissociative disorder
- EPI
- TIA
- Vertigo
- Factitious disorder
- Malingering
- Myoclonus (from metabolic disturbance)

WORKUP

- EEG (Fig. 2). An EEG can help confirm the presence of epilepsy but cannot be used to exclude the diagnosis.
- Ambulatory EEG and/or video EEG recommended for patients with diagnostic uncertainty.

LABORATORY TESTS

- Routine blood workup (CBC, CMP, glucose, electrolytes)
- Urine drug screen
- Lumbar puncture is recommended in patients with suspicion of meningitis

IMAGING STUDIES

- Neurodiagnostic imaging studies such as CT of the head or, preferably, MRI of the brain should be performed in all patients with first unprovoked seizure.
- CT scans of the head should be avoided in children due to unnecessary exposure to radiation and the low yield of the test. CT scans of the head are reserved for neurologic emergencies and are adjusted for weight in children.

TREATMENT

- The immediate management of a seizure focuses on stabilization of the patient with focus on the airway and vital signs and rapid identification and correction of reversible causes.
- Seizures lasting >5 minutes or multiple seizures without return to baseline in between should be treated as status epilepticus.
- Treatment is based on the type and etiology of seizures (i.e., metabolic disturbance, infectious, etc.).
- Provoked seizures due to metabolic derangements, infections, fever, alcohol, or drug-withdrawal are typically generalized and likely do not need long-term treatment.
- Multiple antiepileptic medication choices are available. Choice depends on side effect profile as well as whether the seizure started focally or is secondary to an idiopathic generalized epilepsy syndrome.

NONPHARMACOLOGIC THERAPY

Not applicable

GENERAL Rx

- First unprovoked seizure with normal imaging, EEG, and laboratory workup requires no treatment.
- Recurrent seizures and seizures with abnormal studies require treatment depending on the etiology.
- Primary generalized epilepsies:
  1. Levetiracetam (Keppra): Initial dose 250 to 500 bid, maximum dose 1500 mg bid.
  2. Lamotrigine (Lamictal): Initial dose 25 mg daily and increase slowly to goal dose 150-250 mg daily (depends on combination of other medications).
  3. Topiramate (Topamax): Initial dose 25 mg bid and increase to usual dose of 100 to 200 mg bid.
  4. Perampanel (Fycompa): Initial dose of 2 mg once daily at bedtime, increments of 2 mg once daily at weekly intervals to a recommended maintenance dose of 8 to 12 mg (adjunctive treatment in patients with epilepsy 12 yr of age and older).
  5. Valproic acid (Depakote): Initial dose: 10 to 15 mg/kg/day (divided bid), maximum dose 60 mg/kg/day. Valproic acid should be avoided in girls and women with childbearing potential due to the risk of teratogenicity.
- Focal epilepsies with secondary generalization: Almost all antiepileptic drugs are approved for focal seizures, either in monotherapy or in adjunct. Carbamazepine, oxcarbazepine, eslicarbazepine, lamotrigine, levetiracetam, or lacosamide are all possibilities among others.

CHRONIC Rx

According to a recent joint American Academy of Neurology and American Epilepsy Society evidence-based guideline on the management of a first unprovoked seizure in adults, there is strong evidence that the risk of a second seizure is highest in the first 2 yr and ranges from 21% to 45%. This risk is higher for patients with prior brain insults such as traumatic brain injury or stroke or those with epileptiform abnormalities on EEG. Significant brain imaging abnormalities and nocturnal seizures also indicate a more elevated risk of recurrent seizures. Chronic treatment with antiepileptic drugs is indicated for ≥2 unprovoked seizures or in patients with one seizure with abnormal workup. However, moderate evidence supports advising the patient that immediate antiepileptic therapy, compared with delaying treatment until a second unprovoked seizure, is likely to reduce the risk of a seizure recurrence in the next 2 yr. Furthermore, the risk of adverse events with antiepileptics ranges from 7% to 31%, with most of these adverse events being mild and reversible. Thus, the practice guideline suggests that under certain circumstances adults with one provoked seizure, even without high-risk EEG or MRI findings, can be treated with antiepileptic drugs because at least in the next 2 yr the risk of a recurrent seizure is reduced. Although there is no strong evidence that such treatment improves quality of life, even one seizure can have negative consequences on social and occupational functioning such as driving, making treatment an attractive option for many.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Not applicable

DISPOSITION

- Patients should avoid situations that may cause injuries or accidents in the event of a seizure, such as climbing ladders, swimming unsupervised, or taking baths (rather than showers).
- No driving until seizure-free in accordance with local laws and regulations.

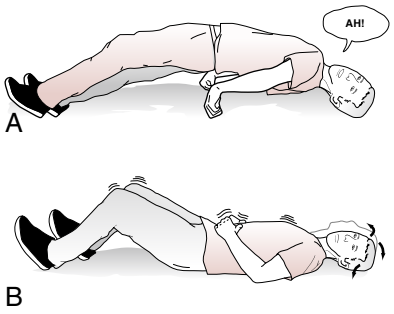

FIG. 1 A, This man in the tonic phase of a tonic-clonic seizure arches his torso and extends his arms and legs. He assumes this position because of the relatively greater strength of the extensor muscles compared to the flexor muscles. Simultaneous diaphragm, chest wall, and laryngeal muscle contractions force air through his tightened larynx to produce the shrill "epileptic cry." During this phase, he may also bite his tongue and lose control of his urine. **B,** In the clonic phase, his head, neck, and legs contract symmetrically and forcefully for about 10 to 20 seconds. Saliva, aerated and often blood-tinged from tongue lacerations, froths from his mouth. His pupils dilate, and he sweats profusely. Finally, his muscular contractions lose strength. The seizure usually ends with stertorous breathing. In the immediate postictal period, he remains unresponsive. Before regaining consciousness, he may pass through a state of confusion and agitation. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

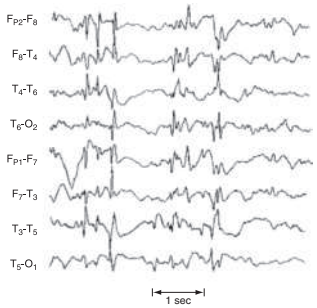

FIG. 2 During a tonic-clonic seizure, the EEG ideally shows paroxysms of spikes, polyspikes, and occasional slow waves in all channels; however, muscle artifact can obscure this pattern. Even during interictal periods, the EEG contains multiple bursts of generalized spikes in the background. In contrast to occasional temporal lobe spikes, this pattern confirms a diagnosis of epilepsy in patients with seizures. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

REFERRAL

Patients with epilepsy and seizures should be referred for a consultation by a neurologist, preferably one with epilepsy training.

PEARLS & CONSIDERATIONS

COMMENTS

- It is crucial to understand that tonic clonic seizures can occur in variety of acute neurologic diseases.
- Successful treatment depends on the correct choice of antiepileptic drugs based on the type (focal onset versus generalized onset) and etiology of the seizures.
- All women of childbearing age taking antiepileptic drugs should take folic acid supplementation (1 to 4 mg/day) for the prevention of neural tube defects.
- Many antiepileptic drugs also affect vitamin D absorption or metabolism, prompting attention to patients' bone health.

PREVENTION

Sleep deprivation and alcohol consumption should be avoided.

PATIENT & FAMILY EDUCATION

Patients with ongoing seizures are forbidden to drive; check your state regulations and laws regarding driving and epilepsy.

BASIC INFORMATION

DEFINITION

Sepsis is an exaggerated inflammatory response to an infectious stimulus. It is usually caused by generalized bacterial or fungal infection and characterized by evidence of infection, fever or hypothermia, hypotension, and evidence of end-organ compromise. The Sepsis Definitions Task Force in 2016 updated definitions for sepsis and septic shock (Table 1). A major change in the definitions is the elimination of mention of SIRS*. According to the new definitions, sepsis is now defined as evidence of infection plus life-threatening organ dysfunction, clinically codified by an acute change in 2 points or greater in the SOFA score (Table 2). The new clinical criteria for septic shock include sepsis with fluid, unresponsive hypotension, serum lactate level greater than 2 mmol/L, and the need for vasopressors to maintain mean arterial pressure of 65 mm Hg or greater.[1,2]

*SIRS (Systemic Inflammatory Response Syndrome): Variables in SIRS criteria include respiratory rate (breaths/min), white blood cell count (109/L), hands (%), heart rate (beats/min), temperature (°C), and arterial carbon dioxide tension (mm Hg). Score range is 0-4.

SYNONYMS

Septicemia
Sepsis syndrome
Severe sepsis
Systemic inflammatory response syndrome
Septic shock

ICD-10CM CODES

A41.9	Sepsis, unspecified organism
A41.50	Gram-negative sepsis, unspecified
A41.2	Sepsis due to unspecified *Staphylococcus*
A41.4	Sepsis due to anaerobes
A41.51	Sepsis due to *Escherichia coli* [E. coli]
A41.52	Sepsis due to Pseudomonas
A54.86	Gonococcal sepsis
B37.7	Candidal sepsis
A32.7	Listerial sepsis
A40.0	Sepsis due to streptococcus, group A
A40.1	Sepsis due to streptococcus, group B
A40.3	Sepsis due to Streptococcus pneumoniae
A40.8	Other streptococcal sepsis
A40.9	Streptococcal sepsis, unspecified
A41.01	Sepsis due to Methicillin susceptible *Staphylococcus aureus*
A41.02	Sepsis due to Methicillin resistant *Staphylococcus aureus*

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Sepsis occurs in 6% of hospitalized patients; approximately half require ICU admission.
- More than 1 million cases of sepsis occur each yr in the U.S. 15% of sepsis patients die in the hospital; 6% are discharged to hospice.

PREDOMINANT SEX: Males are slightly more commonly affected than females.

PREDOMINANT AGE:

- Neonatal period.
- Patients >65 yr of age account for 60% of all cases of sepsis.

GENETICS:

- Familial disposition: A great variety of congenital immunodeficiency states and other inherited disorders may predispose to septicemia.
- Neonatal infection: Incidence is high in neonatal period.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever or hypothermia
- Hypotension
- Tachycardia
- Tachypnea
- Altered mental status
- Bleeding diathesis
- Skin rashes
- Symptoms that reflect primary site of infection: Urinary tract, GI tract, CNS, respiratory tract
- Table 3 describes some clinical signs and symptoms of sepsis

ETIOLOGY

- Disseminated infection with a great variety of bacteria:
  1. Gram-negative bacteria:
     a. *Escherichia coli*
     b. *Klebsiella* spp.
     c. *Pseudomonas aeruginosa*
     d. *Proteus* spp.
     e. *Neisseria meningitides*
  2. Gram-positive bacteria:
     a. *Staphylococcus aureus* (including MRSA)
     b. *Streptococcus* spp.
     c. *Enterococcus* spp.
- Less common infections:
  1. Fungal

TABLE 1 Proposed New Definitions of Sepsis

Term	Definition	Criteria	Notes
Sepsis[a] (previously severe sepsis)	Life-threatening organ dysfunction caused by a dysregulated host response to infection	Organ dysfunction is identified as an acute change in the SOFA score, ≥2 points from the baseline consequent to the infection.	qSOFA (quick Sequential Organ Failure Assessment) Prolonged ICU stay or in-hospital mortality can be identified at the bedside with qSOFA. 1. Respiratory rate ≥22 breaths/min 2. Acute mental status change 3. Systolic blood pressure ≤100 mm Hg An increase in SOFA of ≥2 predicts a 10% mortality in the general hospital population. Presume a baseline SOFA of 0 unless the patient has known (acute or chronic) organ dysfunction before the onset of infection.
Septic shock	It is a subset of sepsis in which the underlying circulatory and cellular/metabolic abnormalities are profound enough to substantially increase mortality.	A clinical construct of sepsis with persisting hypotension requiring vasopressors to maintain MAP ≥65 mm Hg and having a serum lactate level ≥2 mmol/L despite adequate volume resuscitation	Septic shock portends hospital mortality in excess of 40%.

[a]Note that the proposed new definitions abandon the previous term "severe sepsis" to describe infection-induced organ dysfunction and now use "sepsis" in its place. The previous condition called "sepsis" is now just called "infection," and when infection is not associated with organ dysfunction, there is no differentiation between infection with or without systemic manifestations.

MAP, Mean arterial pressure.

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult*, ed 5, Philadelphia, 2019, Elsevier.

TABLE 2 The Sequential Organ Failure Assessment (SOFA) Score

Score	0	1	2	3	4
Respiration					
PaO_2/FiO_2, mm Hg	>400	≤400	≤300	≤200 With respiratory support	≤100

2. Viral
3. Rickettsial
4. Parasitic

- Sepsis is a complex dysregulation of both inflammation and coagulation (Fig. E1). There is activation of coagulation, inflammatory cytokines, complement, and kinin cascades with release of a variety of vasoactive endogenous mediators. The innate immune system recognizes pathogens by means of pattern-recognition receptors (toll-like receptors [TLRs], Table 4). TLRs bind to structures on microorganisms and, based on the composite information gained, generate a tailored response to the invading pathogen.
- Predisposing host factors:
  1. General medical condition
  2. Extremes of age
  3. Immunosuppressive therapy
  4. Recent surgery
  5. Granulocytopenia
  6. Hyposplenism
  7. Diabetes
  8. Instrumentation

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cardiogenic shock
- Acute pancreatitis
- Pulmonary embolism
- Systemic vasculitis
- Toxic ingestion
- Exposure-induced hypothermia
- Fulminant hepatic failure
- Collagen-vascular diseases

WORKUP

- Evaluation should focus on identifying a specific pathogen and localizing the site of primary infection. Box 1 summarizes a general approach to shock.
- Hemodynamic, metabolic, coagulation disorders should be carefully characterized.
- Intensive monitoring.

LABORATORY TESTS

- Cultures of blood and examination and culture of sputum, urine, wound drainage, stool, and CSF, depending on the presenting signs and symptoms for each patient
- CBC with differential, coagulation profile
- Routine chemistries, LFTs
- ABGs, lactic acid level
- Procalcitonin can be useful as a serum marker of bacterial infection as a cause of the sepsis, and has been shown to improve survival and facilitate earlier discontinuation of antibiotics
- Urinalysis

IMAGING STUDIES

- Chest x-ray
- Other radiographic and radioisotope procedures according to suspected site of primary infection

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Tissue oxygenation: Mixed venous oxygen saturation maintained >70% if possible; early mechanical ventilation with low tidal volume (6 ml/kg predicted body weight) to protect lung parenchyma from overstretching and "volutrauma." Recommended plateau pressure for sepsis-related ARDS is ≤30 cm H_2O.
- Focal infection should be drained if possible, and potentially infected catheters should be removed.

ACUTE GENERAL Rx

- Blood pressure support, rapid IV fluid resuscitation and vasopressors (Table 5), if needed, with the goal of reestablishing a mean arterial blood pressure >65 mm Hg; reduction in blood lactate and improved mixed venous oxygen saturation >70% within 6 hr of recognition of septic shock is associated with improved survival. If possible, measure vena cava oxygen

TABLE 4 Toll-Like Receptors

Toll-Like Receptor	Pathogen or Disease State
TLR1	Lyme disease
	Neisseria meningitidis
TLR2	*Mycobacterium tuberculosis*
	Chagas disease
	Leptospirosis
	Fungal sepsis
	CMV viremia
TLR3	Many
TLR4	Gram-negative bacteria
	Septic shock

BOX 1 General Approach to Shock: Initial Diagnosis and Evaluation

- Clinical (primary diagnosis)
  - Tachycardia, hypotension (systolic blood pressure <90 mm Hg) tachypnea, oliguria, encephalopathy (confusion), peripheral hypoperfusion (mottled extremities), cyanosis
- Laboratory (confirmatory)
  - Hemoglobin, WBC, platelets
- Prothrombin time/partial thromboplastin time
  - Electrolytes, arterial blood gases, Ca, Mg, BUN, creatinine, serum lactate
  - ECG
- Monitoring (continuous ECG and respiratory monitors)
  - Pulse oximetry
  - Urinary catheter (urine output)
  - Point-of-care ultrasonography (heart, lung, abdominal, and major vessels)
  - Arterial pressure catheter
  - Central venous pressure monitor (uncomplicated shock)
  - Pulmonary artery flotation catheter
    - Cardiac output
    - Pulmonary artery occlusion pressure
    - Central and/or mixed venous oxygen saturation (intermittent or continuous)
  - Oximetry[a]
- Imaging (chest x-ray)
  - X-ray views of abdomen[a]
  - Computed tomographic scan: Abdomen or chest[a]
  - Formal transthoracic and/or transesophageal echocardiogram[a]

[a]Optional.
BUN, Blood urea nitrogen; *Ca,* calcium; *ECG,* electrocardiogram; *Mg,* magnesium; *WBC,* white blood cell.

saturation ($ScvO_2$) to assess adequacy of resuscitation. If the $ScvO_2$ is <70%, consider packed red blood cell transfusion to achieve Hct >30%. Start inotropic agents if $ScvO_2$ is <70% despite transfusion and adequate fluid resuscitation.

1. IV hydration; patients receiving balanced crystalloids as resuscitation fluids. appear to have a lower 30-day mortality compared with patients who received saline (26% versus 31%) in a recent trial.[1] Use the fluid challenge technique to evaluate the effect (and safety) of fluid administration. For sepsis-induced hypoperfusion, give 30 ml/kg of IV crystalloids within 3 hours, with additional fluid based on frequent reassessment using dynamic variables (e.g., passive leg raise test or pulse or stroke volume variations induced by mechanical ventilation) rather than previous guidelines using target-specific values of central venous pressure. Fluid administration should be discontinued when the response to fluids is no longer beneficial. Most patients need 4 to 6 L of fluid in the first 6 hours. Trials have shown that resuscitation with balanced crystalloids or albumin compared with other fluids seems to be associated with reduced mortality, and that albumin replacement in addition to crystalloids alone does not improve the rate of survival at 28 and 90 days.

[1]Brown RM et al: Balanced Crystalloids versus Saline in Sepsis. A Secondary Analysis of the SMART Clinical Trial *Am J Respir Crit Care Med* 200:1487-1495, 2019.

TABLE 6 Empirical Antibiotic Options for Patients with Severe Sepsis or Septic Shock

	Suspected Source				
	Lung	**Abdomen**	**Skin/Soft Tissue**	**Urinary Tract**	**Source Uncertain**
Major Community-Acquired Pathogens	*Streptococcus pneumoniae* *Haemophilus influenzae* *Legionella* *Chlamydia pneumoniae*	*Escherichia coli* *Bacteroides fragilis*	*Streptococcus pyogenes* *Staphylococcus aureus* Polymicrobial	*E. coli* *Klebsiella* species *Enterobacter* species *Proteus* spp. *Enterococci*	
Empirical Antibiotic Therapy	Moxifloxacin *or* levofloxacin *or* azithromycin *plus* cefotaxime *or* ceftazidime *or* cefepime *or* piperacillin-tazobactam	Imipenem *or* meropenem *or* doripenem *or* Piperacillin-tazobactam ± aminoglycoside If biliary source: Piperacillin-tazobactam, ampicillin-sulbactam, *or* ceftriaxone with metronidazole	Vancomycin *or* daptomycin *plus either* imipenem *or* meropenem *or* piperacillin-tazobactam; ± clindamycin (see text)	Ciprofloxacin *or* levofloxacin (if gram-positive cocci, use ampicillin *or* vancomycin ± gentamicin)	Vancomycin *plus either* doripenem *or* ertapenem *or* imipenem *or* meropenem
Major Commensal or Nosocomial Microorganisms	Aerobic gram-negative bacilli	Aerobic gram-negative rods Anaerobes *Candida* spp.	*Staphylococcus aureus* (? MRSA) Aerobic gram-negative rods	Aerobic gram-negative rods *Enterococci*	Consider MDRO if in area of high prevalence. Consider echinocandin if neutropenic or indwelling intravascular catheter
Empirical Antibiotic Therapy	Imipenem *or* meropenem *or* doripenem *or* cefepime (if *Acinetobacter baumannii* or carbapenem-resistant *Klebsiella* in ICU, add colistin)	Imipenem *or* meropenem ± aminoglycoside (consider echinocandin)	Vancomycin *or* daptomycin *plus* imipenem-cilastatin *or* meropenem *or* cefepime, ± clindamycin	Vancomycin *plus* imipenem *or* meropenem *or* cefepime	Cefepime *plus* vancomycin ± caspofungin

Dosages for intravenous administration (normal renal function):
- Imipenem-cilastatin, 0.5-1.0 g q6-8h
- Meropenem, 1-2 g q8h
- Doripenem, 0.5 g q8h
- Piperacillin-tazobactam, 3.375 g q4h or 4.5 g q6h
- Vancomycin, load 25-30 mg/kg, then 15-20 mg/kg q8-12h
- Cefepime, 1-2 g q8h
- Levofloxacin, 750 mg q24h
- Ciprofloxacin, 400 mg q8-12hr
- Moxifloxacin, 400 mg qd
- Ceftriaxone, 2 g q24h
- Caspofungin, 70 mg, followed by 50 mg q24h
- Colistin: loading dose = 5 mg/kg body weight.

ICU, Intensive care unit; *MDRO*, multidrug-resistant organisms; *MRSA*, methicillin-resistant *Staphylococcus aureus*.
For MDRO, resistance usually includes carbapenems.
Carbapenems are less susceptible to extended-spectrum β-lactamases; base choice on local resistance pattern.
From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

2. Therapy with vasopressors if mean arterial blood pressure of >65 mm Hg cannot be maintained by hydration alone. Use norepinephrine as a first-choice vasopressor and target a mean arterial pressure (MAP) of 65 mm Hg.

- Correction of acidosis by improving the tissue perfusion, not by giving bicarbonate. Mechanical ventilation as needed
- Antibiotics:
  1. Directed at the most likely sources of infection. Table 6 describes initial antibiotic recommendations for septic patients.
  2. Should generally provide broad coverage of gram-positive and gram-negative bacteria (or fungi if clinically indicated).
  3. Antibiotics should be administered within 1 hr of the diagnosis of septic shock—this is a medical emergency.
- The role of corticosteroids in the acute management of septicemia has long been debated. Previous trials had shown that corticosteroid therapy improved hemodynamic outcomes in patients with severe septic shock. Patients with relative adrenal insufficiency may benefit from low-dose therapy with hydrocortisone (200 mg IV by continuous infusion for 7 days). Recent trials, however, revealed that hydrocortisone did not improve survival or reversal of shock, either overall or in patients who did not have a response to corticotropin, although hydrocortisone hastened reversal of shock in patients in whom shock was reversed. Until definitive data are available, the decision to administer corticosteroids for septic shock should be based on the individual patient's severity of illness versus risk of corticosteroid administration. Current evidence and guidelines support limiting the use of IV hydrocortisone for patients with septic shock to these instances with fluid resuscitation and vasopressor therapy are inadequate to restore hemodynamic stability.[2] A recent meta-analysis revealed that although 28 day mortality is lower with corticosteroids in adult patients with sepsis, that effect does not persist at 90 days.[3] The corticotropin (ACTH) stimulation test is not helpful and should not be used to determine the need for corticosteroid in these patients.
- Blood transfusion: A lower hemoglobin threshold is preferred. Trials have shown that among patients with septic shock, mortality at 90 days and rates of ischemic events and use of life support is similar among those assigned to blood transfusion at a higher hemoglobin threshold (hemoglobin level of 9 g/dl or less) and those

[2]Yende S, Thompson T: Evaluating glucocorticoids for sepsis. Time to change course, *JAMA* 316(17):1769–1770, 2016.
[3]Fang F et al: Association of corticosteroid treatment with outcomes in adult patients with sepsis: a systematic review and meta-analysis, *JAMA Intern Med* 179(2):213–223, 2019.

assigned to blood transfusion at a lower threshold (hemoglobin level of 7 g/dl or less).

CHRONIC Rx

- Adjust antibiotic therapy on the basis of culture results.
- In general, continue antibiotic therapy for a minimum of 7 to 10 days.
- Infection source control (e.g., removal of catheter/device suspected to be infected).
- If hyperglycemia develops during treatment, start continuous insulin IV infusion, maintain blood glucose in the 110 to 180 mg/dl level, and avoid insulin-induced hypoglycemia.

DISPOSITION

- All patients with sepsis should be hospitalized and given access to intensive monitoring and nursing care.
- Among adults with suspected infection admitted to an ICU, an increase in SOFA score of 2 or more has greater prognostic accuracy for in-hospital mortality than SIRS criteria or the qSOFA score (quick SOFA).[4] The qSOFA can be done at bedside and consists of increased respiratory rate ≥ 22/min, altered mentation and systolic BP ≤100 mm Hg with each allocated 1 point.

REFERRAL

- To infectious diseases expert
- To physician experienced in critical care

PEARLS & CONSIDERATIONS

COMMENTS

- Mortality rises quickly if antibiotic therapy is not instituted promptly (preferably within 1 hr of onset of shock) and metabolic derangements are not treated aggressively.
- The Surviving Sepsis Campaign hour-1 bundle 2018 update recommends: Measure lactate level. Re-measure if initial lactate is >2 mmol/L. [weak recommendation, low quality of evidence] Obtain blood cultures prior to administration of antibiotics. [best practice statement] Administer broad spectrum antibiotics. [strong recommendation, moderate quality of evidence] Rapidly administer 30 ml/kg crystalloid for hypotension or lactate ≥4 mmol/L [strong recommendation, low quality of evidence] and apply vasopressors if patient is hypotensive during or after fluid resuscitation to maintain MAP ≥65 mm Hg. [strong recommendation, moderate quality of evidence]
- Recent trials have shown that early, goal-directed therapy (EGDT) does not result in better outcomes than usual care and is associated with higher hospitalization costs across a broad range of patient and hospital characteristics.[5]

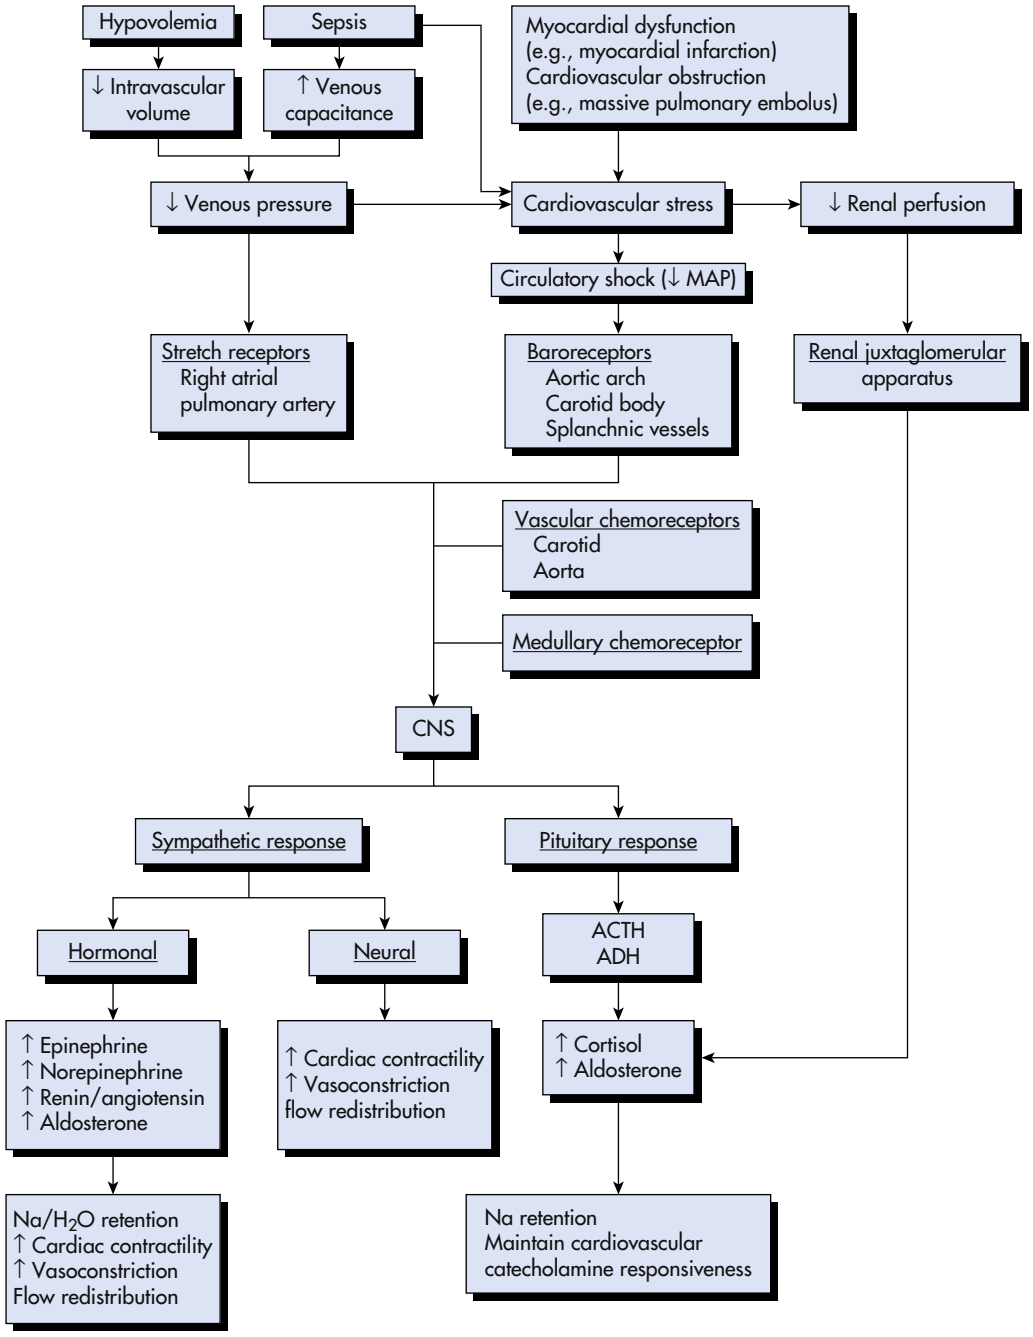

FIG. E1 Neurohormonal response to shock. During early cardiovascular stress, the neurohormonal response may be limited to increased activity of the juxtaglomerular apparatus and stimulation of right atrial and pulmonary artery low-pressure mechanoreceptors. With further hypotension, high-pressure vascular baroreceptors, vascular chemoreceptors, and the medullary chemoreceptor are stimulated sequentially. This results in augmented neurohormonal activity with increased pituitary hormone (adrenocorticotropic hormone *[ACTH]* and antidiuretic hormone *[ADH]*) release and increased sympathetic outflow from the central nervous system *(CNS)*. Volume retention, increased venous tone, increased cardiac contractility, and blood flow redistribution to vital organs are the results. *MAP,* Mean arterial pressure; *Na,* sodium; *H_2O,* water. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult*, ed 5, Philadelphia, 2019, Elsevier.)

Septic Arthritis ALG PTG

BASIC INFORMATION

DEFINITION

Septic arthritis is a highly destructive form of joint disease most often caused by hematogenous spread of organisms from a distant site of infection. Direct penetration of the joint as a result of trauma or surgery and spread from adjacent osteomyelitis may also cause bacterial arthritis. Any joint in the body may be affected.

SYNONYMS

Infectious arthritis
Bacterial arthritis
Pyogenic arthritis

ICD-10CM CODE
M00.9 Pyogenic arthritis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Between 2 and 6 cases per 100,000 people per yr
PREVALENCE (IN U.S.): Unknown
PREDOMINANT SEX: Gonococcal arthritis in females
PREDOMINANT AGE: Gonococcal arthritis in sexually active adults
PEAK INCIDENCE:
- Gonococcal arthritis: Young adults
- Other bacterial causes: All ages

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Hallmark: Acute onset of monoarticular joint pain, erythema, heat, and immobility
- Limited range of motion of the joint
- Effusion, with varying degrees of erythema and increased warmth around the joint
- Single joint affected in 80% to 90% of cases of nongonococcal arthritis
- Gonococcal dermatitis-arthritis syndrome:
  1. Typical pattern is a migratory polyarthritis or tenosynovitis
  2. Small pustules on the trunk or extremities
- Febrile patient at presentation
- Most commonly affected joints in adult: Knee and hip, but any joint may be involved; in children—hip

ETIOLOGY

- Bacteria spread from another locus of infection.
  1. Highly vascular synovium is invaded by hematogenously spread bacteria.
  2. WBC enzymes cause necrosis of synovium, cartilage, and bone.
  3. Extensive joint destruction is rapid if infection is not treated with appropriate IV antibiotics and drainage of necrotic material.
- Predisposing factors: Rheumatoid arthritis, prosthetic joints, advanced age, immunodeficiency (HIV, DM, immunosuppressive drugs), gout, sexual activity (gonococcal arthritis), skin infections, cutaneous ulcers (contiguous spread), recent joint surgery, recent intraarticular infection. Fig. E1 illustrates routes by which bacteria can reach the joint.
- The most common nongonococcal organisms are staphylococci (40%), streptococci (28%), and gram-negative bacilli (19%). Less common are mycobacteria (8%), gram-negative cocci (3%), anaerobes (1%), and gram-positive bacilli (1%).
- Staphylococci (*S. aureus* and coagulase-negative staphylococcal species) account for >50% of prosthetic-hip and prosthetic-knee infections. *S. aureus* is very common in patients with rheumatoid arthritis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gout
- Pseudogout
- Trauma
- Hemarthrosis
- Rheumatic fever
- Adult or juvenile rheumatoid arthritis
- Spondyloarthropathies such as reactive arthritis (Reiter syndrome)
- Osteomyelitis
- Viral arthritides
- Septic bursitis
- Lyme disease caused by *Borrelia burgdorferi*

WORKUP

- Joint aspiration, Gram stain, and culture of the synovial fluid. Fig. 2 describes an algorithm for synovial fluid analysis in septic arthritis.
- Immediate arthrocentesis before other studies are undertaken or antibiotics instituted. Synovial fluid should be evaluated at bedside and then sent for lab evaluation.

LABORATORY TESTS

- Joint fluid analysis:
  1. Synovial fluid leukocyte count is usually elevated >50,000 cells/mm^3 with >80% polymorphonuclear cells.
  2. Counts are highly variable, with similar findings in gout, pseudogout, or rheumatoid arthritis. Lower WBC counts can occur in joint replacement, disseminated gonococcal disease, and peripheral leukopenia.
  3. Synovial fluid glucose or protein is not helpful because results are not specific for septic arthritis. The differential diagnosis of synovial fluid abnormalities is described in Section IV.
  4. PCR testing: Useful for detection of uncommon organisms (e.g., Lyme disease).
  5. Crystal analysis: Septic arthritis can coexist with crystal arthropathy; therefore, the presence of crystals does not preclude a diagnosis of septic arthritis.
- Blood cultures: Positive in 25% to 50% of patients with septic arthritis.
- Culture of possible extraarticular sources of infection.
- Elevated peripheral WBC count, ESR (nonspecific), C-reactive protein (CRP) (nonspecific). When elevated, ESR and CRP may be useful to monitor therapeutic response.
- If gonococcus is suspected, perform nucleic acid amplification tests (NAATs) on synovial fluid.

IMAGING STUDIES

- Radiograph of the affected joint (Fig. E3): Useful to rule out osteomyelitis, fractures, chondrocalcinosis, or inflammatory arthritis
- MRI: Findings that suggest an acute intraarticular infection include the combination of bony erosions with marrow edema
- CT scan: Useful for early diagnosis of infections of the spine, hips, and sternoclavicular and sacroiliac joints
- Ultrasound: Can be useful for detecting effusions in joints that are more difficult to examine (e.g., hip)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Affected joints aspirated daily to remove necrotic material and to follow serial WBC counts and cultures
- If no resolution with IV antibiotics and closed drainage: Open debridement and lavage, particularly in nongonococcal infections
- Prevention of contractures:
  1. After acute stage of inflammation, range-of-motion exercises of the affected joint
  2. Physical therapy helpful

ACUTE GENERAL Rx

- IV antibiotics immediately after joint aspiration and Gram stain of the synovial fluid. Empiric antibiotic therapy (Table E1) is based on organism found on Gram stain of synovial fluid:
  1. Gram-positive cocci: Vancomycin: 15 to 20 mg/kg IV q8 to 12h. Keep trough levels at 15 to 20 mcg/ml. Alternatives include daptomycin and linezolid
  2. Gram-negative cocci: Ceftriaxone: 1 to 2 g IV q day in adults (children: 50 to 100 mg/kg IV q day). Alternative includes cefotaxime
  3. Gram-negative rods: Ceftriaxone, cefepime: 1 to 2 g IV q8 to 12h in adults (children: 100 to 150 mg/kg/day divided in q8h dosing), piperacillin-tazobactam: 3.375 g IV to 4.5 g IV q6h. Aztreonam or fluoroquinolones can be used in patients with allergy to penicillin or cephalosporins
  4. Negative Gram stain: Vancomycin plus either cefepime or a carbapenem such as meropenem: 1 g IV q8h in adults (children: 60 mg/kg/day divided in q8h dosing) or ertapenem

The optimal duration of antibiotic use in septic arthritis has traditionally been 3 to 6 wk usually following surgical drainage. Recent trials (Gjika et al, *Ann Rheum Dis* Aug 2019, 78: 1114) support a 2-wk course in conjunction with surgery.

TABLE E1 Recommended Empiric Therapy for Adult Native Joint Bacterial Arthritis

Gram Stain	Preferred Antibiotic*	Alternative Antibiotic
Gram-positive cocci	Vancomycin, 15-20 mg/kg (ABW) daily every 8-12 hr†	Daptomycin, 6-8 mg/kg daily™™ *or* linezolid, 600 mg IV or PO every 12 hr‡
Gram-negative cocci§	Ceftriaxone, 1 g every 24 hr	Cefotaxime, 1 g every 8 hr ‖
Gram-negative rods¶	Ceftazidime, 2 g every 8 hr *or* cefepime, 2 g every 8 hr *or* piperacillin-tazobactam, 4.5 g every 6 hr	Aztreonam, 2 g every 8 hr *or* fluoroquinolone *or* carbapenem
Gram stain negative¶	Vancomycin plus ceftazidime *or* cefepime	Daptomycin‡ *or* linezolid‡ plus piperacillin-tazobactam *or* aztreonam *or* fluoroquinolone** *or* carbapenem

*Unless noted otherwise, dosages are IV for persons with normal renal function.
†Therapeutic monitoring should target a serum trough of 15-20 mg/L.
‡For patients allergic to, or intolerant of, vancomycin.
§Equivocal gram-negative morphology should be considered as gram-negative rods.
‖ Gram-negative cocci with epidemiology or history suggestive of gonococcal infection should be initially treated per Centers for Disease Control and Prevention Sexually Transmitted Disease Guidelines. Alternative therapies have not been suggested for patients with a history of a Stevens-Johnson syndrome or severe IgE-mediated allergy to β-lactam antibiotics. Possible empiric options for penicillin-allergic patients, pending culture sensitivities, include azithromycin, ciprofloxacin, tobramycin, gentamicin, and spectinomycin (not available in U.S.).
¶For patients with risk factors for resistant gram-negative pathogens (significant health care exposure, immunosuppression, or history of extended-spectrum β-lactamase gram-negative infection or colonization), drug selection should consider regional or local antibiograms.
**Ciprofloxacin, 400 mg IV q8h or 750 mg PO q12h *or* levofloxacin, 750 mg IV or PO q24h.

Serotonin Syndrome

BASIC INFORMATION

DEFINITION

Serotonin syndrome (SS) is a potentially life-threatening condition resulting from excessive serotonergic stimulation of 5-HT_{1A} and 5-HT_{2A} receptors in the CNS and PNS. SS is a drug-induced disorder that is classically characterized by mental status changes, neuromuscular hyperactivity, and autonomic dysfunction.

SYNONYMS

SS
Hyperserotonemia
Serotonergic syndrome
Serotonin toxicity

ICD-10CM CODES

Y49	Adverse effects due to psychotropic drugs
Y49.0	Adverse effects due to tricyclic and tetracyclic antidepressants
Y49.1	Adverse effects due to monoamine-oxidase-inhibitor antidepressants
Y49.2	Adverse effects due to other and unspecified antidepressants
Y49.3	Adverse effects due to phenothiazine antipsychotics and neuroleptics
G25.89	Other specified extrapyramidal and movement disorders

EPIDEMIOLOGY & DEMOGRAPHICS

- The true incidence of SS is not known, as clinical manifestations may go unnoticed or be attributed to another condition.
- SS is seen in all age groups.
- SS classically occurs in patients receiving two or more serotonergic drugs, but it can also occur with monotherapy—selective serotonin reuptake inhibitor (SSRI) monotherapy has an incidence of 0.5 to 0.9 cases of SS per 1000 patient-mo. Although there is an FDA alert, it has been argued that there is a lack of sufficient evidence showing that SSRIs and triptans cause serious SS.
- Concomitant use of an SSRI with a monoamine oxidase inhibitor (MAOI) poses the greatest risk of developing SS.
- Combination of SSRIs with other serotonergic drugs (e.g., tryptophan, illicit drugs like cocaine and MDMA, "Ecstasy") or drugs with serotonergic properties (e.g., methylene blue, lithium, meperidine, triptans, linezolid) may also lead to SS.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Findings of clonus with hyperreflexia in the setting of recent (<5 wk) use of serotonergic agents strongly suggest the diagnosis of SS.
- Symptoms can manifest within min to hours after starting a new psychopharmacologic treatment, increasing the dose of a serotonergic drug, or administering a second serotonergic drug.
- Clonus (inducible, spontaneous, and ocular) is the key finding in establishing a diagnosis of SS.
- Classic triad of clinical features:
  1. Neuromuscular excitation: Hyperreflexia, myoclonus, muscle rigidity, tremor
  2. Autonomic nervous system excitation: Nausea/vomiting, diarrhea, hypertension, tachycardia, diaphoresis, fever >38° C (100° F) to severe hyperthermia
  3. Altered mental status: Anxiety, agitation, confusion, coma

ETIOLOGY

- Hyperstimulation of the brain stem and spinal cord serotonin receptors leading to the neuromuscular and autonomic symptoms.
- Psychopharmacologic drugs—in particular, fluoxetine and sertraline co-administered with MAOI (e.g., tranylcypromine and phenelzine)—have been cited as a common cause of SS. Triptans (serotonin-receptor agonists used in the treatment of migraines) may also precipitate the SS when used in combination with SSRIs and serotonin-norepinephrine reuptake inhibitors (SNRIs). Box 1 describes classes of medications that produce SS.

BOX 1 Classes of Medications That Produce Serotonin Syndrome in Psychiatric Patients

Selective serotonin reuptake inhibitors
Monoamine oxidase inhibitors
Atypical antipsychotics
Heterocyclic antidepressants
Trazodone
Dual-uptake inhibitors
Psychostimulants
Buspirone
Mood stabilizers
Analgesics
Antiemetics
Cough suppressants
Dietary supplements
Linezolid

From Goldman L, Schafer AI: *Goldman-Cecil medicine*, ed 24, Philadelphia, 2012, Saunders.

DIAGNOSIS

- SS is a clinical diagnosis. There are no specific laboratory tests for SS. A high index of suspicion along with a detailed medication history is the mainstay of diagnosis.
- Diagnostic criteria: Most accurate is Hunter Serotonin Toxicity Criteria (sensitivity 84%, specificity 97%, confirmation by toxicologist). Sternbach diagnostic criteria (Table 1) are also commonly used.
- To fulfill Hunter criteria a patient must have consumed a serotonergic drug and have one of the following:
  1. Spontaneous clonus
  2. Inducible clonus plus agitation or diaphoresis
  3. Ocular clonus plus agitation or diaphoresis
  4. Tremor and hyperreflexia
  5. Temperature >38° C (100° F) plus hypertonia plus ocular clonus or inducible clonus

DIFFERENTIAL DIAGNOSIS

- Neuroleptic malignant syndrome (NMS), substance abuse (e.g., cocaine, amphetamines), anticholinergic toxicity, malignant hyperthermia, thyroid storm, infection (e.g., meningitis, encephalitis), alcohol and opioid withdrawal.
- Classic features in differentiation of NMS from SS are that SS develops over 24 hr, involves neuromuscular hyperactivity (hyperreflexia, myoclonus), and begins to resolve within 24 hr with appropriate therapy, whereas NMS develops gradually over days to wks, involves sluggish neuromuscular response, and resolves over an average period of 1 wk to 10 days.

WORKUP

- Because SS is a clinical diagnosis, there is no laboratory test that confirms the diagnosis, and serum serotonin concentration does not correlate with the clinical picture. Other causes

TABLE 1 Criteria to Determine Serotonin Syndrome and Toxicity

Sternbach diagnostic criteria for serotonin syndrome	1. Recent addition or increase of proserotonergic medication 2. At least three of the following: 1. Agitation 2. Ataxia 3. Diaphoresis 4. Diarrhea 5. Hyperreflexia 6. Hyperthermia 7. Mental status changes 8. Myoclonus 9. Shivering 10. Tremor 3. Neuroleptic agent not added or dose increased before the onset of symptoms 4. Diagnosis of infections, withdrawal, and other poisoning or metabolic disruptions excluded
Hunter criteria for serotonin toxicity (context of serotonergic medications)	1. If patient has spontaneous clonus, serotonin toxicity present 2. If no spontaneous clonus, one of the following needed for a diagnosis of serotonin toxicity: 1. Inducible clonus *and* agitation *or* diaphoresis 2. Ocular clonus *and* agitation *or* diaphoresis 3. Tremor *and* hyperreflexia 4. Temperature >38° C *and* ocular clonus *or* inducible clonus

From Adams JG et al: *Emergency medicine, clinical essentials*, ed 2, Philadelphia, 2013, Elsevier.

are described in "Differential Diagnosis." Thus, all patients should have blood tests and diagnostic imaging studies to rule out infectious, toxic, and metabolic causes.
- Additional laboratory tests are performed to exclude complicating features of SS (e.g., renal failure secondary to rhabdomyolysis).

LABORATORY TESTS

- CBC with differential when considering sepsis
- Urine and blood cultures
- Electrolytes, BUN, and creatinine to rule out acidosis and renal failure
- Coagulation studies to rule out disseminated intravascular coagulation
- Blood and urine toxicology screen, including acetaminophen and salicylate levels if overdose was intentional
- Thyroid function tests
- Creatine-phosphokinase (CPK) with isoenzymes
- ECG because ventricular rhythm disturbance is a potentially fatal complication
- CSF studies to rule out meningitis

IMAGING STUDIES

Imaging studies are not specific in the diagnosis of SS and are only ordered to exclude other causes with similar clinical presentations as SS.

Rx TREATMENT

- Once a diagnosis of SS is established, consultation with a medical toxicologist, clinical pharmacologist, and/or poison control center should be considered
- Management includes:
  1. Discontinue use of all potential precipitating drugs.
  2. Provide supportive management.
  3. Control agitation.
  4. Administer serotonin antagonists.
  5. Control autonomic instability.
  6. Control hyperthermia.
  7. Reassess the need to resume the use of the serotonergic agent once the symptoms have resolved.

NONPHARMACOLOGIC THERAPY

- Discontinuation of the drug is the mainstay of therapy.
- Treatment is supportive: Maintaining oxygenation and blood pressure and monitoring respiratory status. Hypotensive patients may require both IV fluids and vasopressor therapy.
- Patients who are severely hyperthermic with temperatures >41° C (106° F) should be given IV sedation, paralyzed, and intubated. Cooling blankets can be used for patients with mild to moderate hyperthermia. There is no role for acetaminophen here.
- Intubation is recommended for patients unable to protect their airways as a result of mental status changes or seizures.

ACUTE GENERAL Rx

- Benzodiazepines for control of agitation are preferred to physical restraints.
  1. Lorazepam 1 to 2 mg IV every 30 min has been used effectively in treating agitation, muscle rigidity, myoclonus, and seizure complications.
  2. Diazepam is an alternative choice.
- Blood pressure management with short-acting agents such as esmolol and nitroprusside.
- Serotonin antagonists should be titrated to clinical effectiveness in patients for whom nonpharmacologic therapy and benzodiazepines are not achieving adequate response, although substantial and rigorous data are lacking.
  1. Cyproheptadine 4 mg tablet or 2 mg/5 ml syrup is given 12 mg initially followed by 2 mg every 2 hr until therapeutic response is achieved in adults (up to 32 mg/day); children ages 7 to 14 should receive 4 mg every 6 hr (up to 16 mg/day), children ages 2 to 6 should receive 2 mg every 6 hr (up to 12 mg/day), and children younger than 2 yr should receive a maximum of 0.25 mg/kg/day as 0.06 mg/kg every 6 hr.
  2. Atypical antipsychotic agents with serotonin antagonist properties (e.g., olanzapine 10 mg SL) have been tried with some success.
  3. Chlorpromazine 50 to 100 mg IM may be considered in severe cases, but intravenous fluid loading is essential to prevent hypotension.

CHRONIC Rx

For patients not requiring hospital admission, cyproheptadine and lorazepam can be given in an oral dose on a prn basis with close follow-up.

DISPOSITION

- SS is a potentially life-threatening condition if not recognized early, although it does exist on a spectrum.
- Prompt diagnosis and withdrawal of the medication result in improvement of symptoms within 24 hr.
- Seizures, rhabdomyolysis, hyperthermia, ventricular arrhythmia, respiratory arrest, and coma are all complicating features of SS.

REFERRAL

All cases of SS secondary to psychotropic medications should be referred to a psychiatrist.

PREVENTION

Modify prescription practices by avoiding multidrug regimens.

PEARLS & CONSIDERATIONS

The combined use of SSRIs and MAOIs is contraindicated.

COMMENTS

- The use of SSRIs and other serotonergic agents is not an absolute contraindication; however, prompt withdrawal of the medication is recommended if any symptoms suggesting SS occur.
- SS is usually found in patients being treated for depression, bipolar disorders, obsessive-compulsive disorder, attention deficit disorder, and Parkinson disease.

PEAK INCIDENCE: As high as 25%
PREVALENCE (IN U.S.): 23 million women, 2.8 million men
PREDOMINANT SEX AND AGE: Female, ages 12 to 34
RISK FACTORS: Alcohol/drug consumption, prior history of being sexually/physically abused, multiple sexual partners, involvement in sex work, poverty, incarceration/institutionalization, intellectual disability

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Extragenital trauma: 70%: Erythema, bruises, abrasions, lacerations, or fractures on thigh, arms, face, neck
- Anogenital trauma: 27%: Injury to breasts, external genitalia, vagina, anus, rectum
- Other: Pregnancy (5%), bullet wounds, death

Physical findings more likely if examined within 72 hr of event, if event occurred outdoors, and if perpetrator was unknown

DIAGNOSIS

WORKUP

Preliminary issues and strategies in preparing for taking the history from a sexual assault victim (SAV) are described in Box E1. Consent issues are summarized in Box E2.

- History:
  1. Circumstances of assault: Date, time, location
  2. Physical description of perpetrator
  3. Areas of trauma, specifically details of oral, vaginal, anorectal contact, or penetration
  4. Condom use
  5. Ejaculation: Presence or absence
  6. Presence of bleeding in victim or perpetrator
  7. Recent consensual sexual activity
  8. Showering, bathing, changing of clothes since event
- Physical examination:
  1. Ideally performed by individual trained to perform sexual assault examinations, i.e., SANE (Sexual Assault Nurse Evaluation) providers: www.sane-sart.com
  2. Physical exam can take 3 to 6 hr to complete
  3. Components:
     a. Physical examination of entire body
     b. Forensic evidence collection
     c. STD evaluation and treatment
     d. Pregnancy risk evaluation
     e. Care of injuries
  4. General physical exam components:
     a. Documentation of any physical trauma, including photographs
     b. Colposcopy: May reveal areas of minor genital trauma
     c. Wood's light: To reveal foreign debris or semen
  5. Forensic evaluation: Not required, but should be offered; written informed consent needed:
     a. Commercially made specimen collection kits available: Once completed, kits need to be sealed and handled according to kit instructions
     b. U.S.: States required to provide free specimen collection
     c. Samples of blood, saliva, mucosal swabs: Buccal/vaginal/rectal, fingernail scrapings/clippings, hair specimens
     d. Clothing: If unchanged since event
- Box E3 summarizes potential specimens to be gathered for forensic evidence collection.
- Fig. E1 describes an algorithm for emergency department management of patients after sexual assault.

LABORATORY TESTS

- Laboratory evaluation of sexual assault is summarized in Table E1
- Pregnancy test (if applicable)
- STD testing:
  1. GC/CT: Recommended for all, may be excluded if individual elects prophylactic treatment
  2. Wet mount or vaginal swab for *Trichomonas*
  3. Baseline HIV/hepatitis/syphilis testing: Individual basis
  4. Retest for HIV/syphilis at 6 wk, 3 mo, and 6 mo from incident

IMAGING STUDIES

Use of imaging studies as dictated by other injuries sustained for diagnosis/treatment of fractures, soft tissue, and other traumatic injuries

TREATMENT

NONPHARMACOLOGIC THERAPY

Acute crisis counseling: To support mental health needs of victim in immediate post-assault period

ACUTE GENERAL Rx

- Post-exposure prophylaxis (PEP) for acute sexual assault victims is summarized in Table E2
- Sexually transmitted infections:

BOX E1 Preliminary Issues and Strategies in Preparing for Taking A Patient History From a Sexual Assault Victim (SAV)

Provide a quiet, confidential, safe environment.
Briefly review the interview and examination process in private with the SAV.
Explain the sensitive, personal, embarrassing nature of questions and the right to be interviewed in private.
Show concern for the SAV's immediate comfort (e.g., if thirsty, take oral swabs first so SAV may drink).
Provide advocacy.
Try to conduct the interview the same way.
Leave difficult questions until the end; some may need to be repeated during appropriate parts of the physical examination.
Explain why you are asking the question and the possible responses.
Explain that all questions will be asked.

From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, WB Saunders.

BOX E2 Consent Issues in Sexual Assault Cases

Consent should specify that the sexual assault victim's signature acknowledges the following:

- That hospitals and health care professionals are mandated reporters and that an anonymous Jane Doe report can be made
- Receipt of information about victim compensation funds
- Specific understanding of examination and evidence collection procedures
- Specific understanding of the use of photography in documenting physical and genital injuries
- That information collected will be sent to law enforcement and is obtainable by defense counsel
- That data without patient identity can be collected for valid educational and scientific purposes
- That consent may be withdrawn at any time
- That there is no charge for the examination, whether reported to law enforcement or not

From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, WB Saunders.

BOX E3 Potential Specimens to Be Gathered for Forensic Evidence Collection

Clothing
- Each article of clothing should be packaged in a separate paper bag to avoid cross-contamination.
- If the patient has changed her clothing, only underwear should be collected.

Known blood sample
- Crime laboratory assesses for secretor status and blood type of the patient.
- Toxicology testing (urine and blood)
- For use in cases in which drug-facilitated sexual assault is suspected
- Collect for evaluation less than 72 to 96 hr after the assault (the time varies by crime laboratory).

Oral swabs and smears
- Collect for evaluation up to 24 hr after the assault.

Head hair combings
Fingernail scrapings
Foreign material collection
Swabs of bite marks or areas where the assailant's mouth touched the patient
Pubic hair combings
External genital swabs

Vaginal swabs and smears
- Cervical sampling should be considered for evaluation between 96 and 120 hr after the assault.

Perianal swabs
Anorectal swabs and smears
- Collect for evaluation up to 24 hr after the assault.

Forensic photography
- Three views per injury, one with a ruler for scale.

From Adams JG et al: *Emergency medicine: clinical essentials*, ed 2, Philadelphia, 2013, Elsevier.

1. Empiric treatment recommended secondary to poor follow-up rates
2. Gonorrhea: Ceftriaxone 250 mg IM *or* cefixime 400 mg PO
3. *Chlamydia:* Azithromycin 1 g (single dose) *or* doxycycline 100 mg bid × 7 days
4. Trichomoniasis: Metronidazole 2 g PO (single dose)

- Hepatitis B:
  1. If perpetrator is known to be infected: HBIG + Hep B vaccination.
  2. If perpetrator disease status unknown: Hep B vaccination alone.
  3. If victim has already been vaccinated with documented immunity: No treatment necessary.
- HIV:
  1. Use of antiretrovirals after sexual assault is controversial.
  2. Overall risk of acquiring HIV is unknown but higher in certain situations:
     a. Male-on-male rapists
     b. Assault occurring in area with high local prevalence
     c. Multiple assailants
     d. Anal sexual assault
     e. Presence of trauma, bleeding, or genital lesions in either victim/assailant
  3. Antiretroviral drugs should be offered in all situations.
  4. Ideally, antiretrovirals are initiated within 4 hr; should not start if >72 hr.
- Pregnancy:
  1. Pregnancy risk is estimated to be 5% per rape in women age 12 to 45.
  2. Emergency contraception should be offered in all cases.
     a. Levonorgestrel: 0.75 mg q12h for two doses or 1.5 mg single dose
     b. Yuzpe regimen: 100 mcg ethinyl estradiol + 0.5 mg levonorgestrel, repeated in 12 hr
     c. Ulipristal (selective progesterone receptor modulator): Preferred method when >72 hr from assault
  3. Antiemetics: EC + antibiotics for STD prophylaxis commonly causes nausea.

CHRONIC Rx

- No chronic prescriptions.
- Long-term psychiatric counseling may be needed.

REFERRAL

Mental health professional

TABLE E1 Laboratory Evaluation of Sexual Assault

Within 8-12 hr (if indicated by history)

Urine and blood for date rape drugs (GHB, Rohypnol, ketamine)

Within 24 hr (if indicated by history)

Blood for comprehensive toxicology screen (for other classes of drugs)

Within 72 hr (or up to 96 hr depending on the protocol used)

Forensic evidence kit
Pregnancy test
Hepatitis B screen (hepatitis B surface antigen, surface antibody, and core antibody)
Syphilis (rapid plasma reagin [RPR], Venereal Disease Research Laboratories [VDRL])
HIV infection
Bacterial vaginosis (BV) and candidiasis: Point-of-care testing and/or wet mouth with measurement of vaginal pH and KOH application for whiff test
Trichomonas vaginalis: Nucleic acid amplification tests (NAATs) by urine or vaginal specimen or point-of-care testing (DNA probes) from vaginal specimen
Chlamydia and Neisse*ria gonorrhoeae*: Nucleic acid amplification testing (NAATs) at sites of penetration or possible penetration:
1. *N. gonorrhoeae:* Oropharynx, rectum, urine*
2. *Chlamydia*: Urine,* rectum

*Dirty urine sample may be used as alternate for genital swab.

From Centers for Disease Control and Prevention: Sexually transmitted diseases: Treatment guidelines 2015, *MMWR Recomm Rep* 64(RR-3):1–140, 2015, and Updated guidelines for antiretroviral postexposure prophylaxis after sexual, injection drug use, or other nonoccupational exposure to HIV—United States, 2016. In Kliegman, RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

TABLE E2 Postexposure Prophylaxis (PEP) for Acute Sexual Assault Victims

Routine

Recommended Regimen for STI Prophylaxis

Ceftriaxone 250 mg intramuscularly
plus
Azithromycin 1g orally in a single dose
plus
Metronidazole 2 g orally in a single dose or
Tinidazole 2 g orally in a single dose

Pregnancy Prophylaxis*

Levonorgestrel (Plan B) 1.5 mg orally in a single dose
or
Ulipristal acetate (Ella) 30 mg is effective for up to 120 hr.

Human Papillomavirus (HPV)

Assess HPV vaccine history; to the unimmunized, administer initial vaccine at initial exam, with 2 follow-up doses at 1 to 2 mo and at 6 mo if >15 yr old or a single follow-up dose at 6-12 mo if ≤15 yr old.

As Indicated

All persons offered PEP should be prescribed a 28-day course of a two- or three-drug antiretroviral regimen.

Human Immunodeficiency Virus (HIV)†

Preferred regimen:
Tenofovir 300 mg and fixed-dose combination emtricitabine, 200 mg (Truvada) once daily
plus
Raltegravir 400 mg twice daily *or*
Dolutegravir 50 mg daily‡

Hepatitis B Virus (HBV)

Specific indications for vaccine, immunoglobulin and/or Booster dependent upon assailant's status

*Provided for patients with negative urine pregnancy screen. In addition, antiemetic (Compazine, Zofran) can be prescribed for patients receiving emergency contraception.

†HIV PEP is provided for patients with penetration and when the assailant is known to be HIV-positive or at high risk because of a history of incarceration, intravenous drug use, or multiple sexual partners. If provided, laboratory studies must be drawn before administration of medication (HIV, CBC, LFTs, BUN/Cr, amylase, lipase), and follow-up must be arranged.

‡Dolutegravir has been associated with neural tube defects if exposure occurs within the first trimester of pregnancy. Therefore, it should be avoided in pregnant patients or those at risk for becoming pregnant.

U.S. Department of Health and Human Services, U.S. Food & Drug Administration. Juluca, Tivicay, Triumeq (dolutegravir): *FDA to evaluate potential risk of neural tube birth defects*. May 18, 2018. In Kliegman, RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

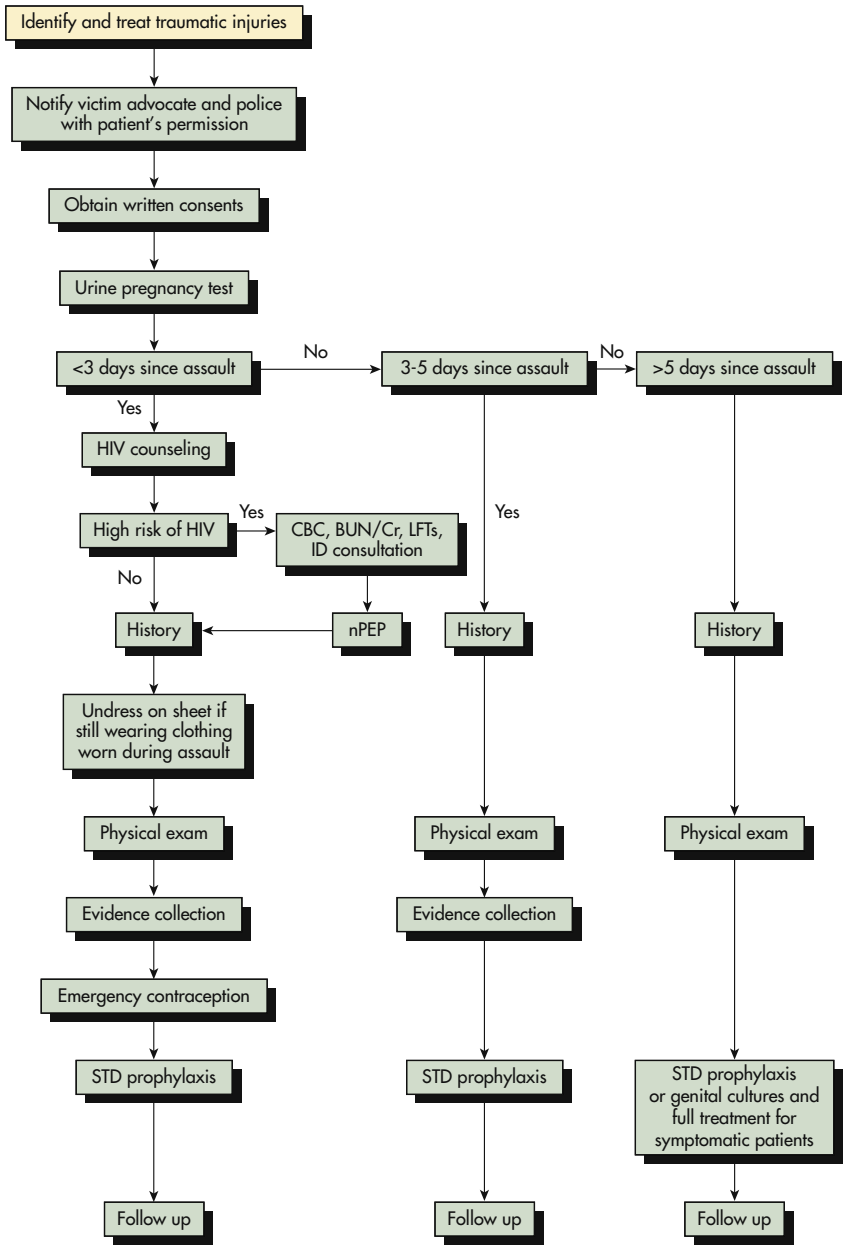

FIG. E1 Emergency department management of patients after sexual assault. *BUN*, Blood urea nitrogen; *CBC*, complete blood count; *Cr*, creatinine; *HIV*, human immunodeficiency virus; *ID*, infectious disease; *LFTs*, liver function tests; *nPEP*, nonoccupational postexposure prophylaxis; *STD*, sexually transmitted disease. BASIC INFORMATION

DEFINITION

A sexual dysfunction in a woman is any disorder that interferes with female sexuality and that causes marked distress to that person. The DSM-5 reclassified these disorders into the following categories:

- Female sexual arousal disorder (FSIAD): Hypoactive sexual desire disorder (HSDD) and female sexual arousal disorder (FSAD) were merged into this category
- Female orgasmic disorders
- Genito-pelvic pain/penetration disorder (GPPD): Combines the diagnoses of dyspareunia and vaginismus
- Sexual dysfunction due to secondary causes (e.g., medication, substance abuse, medical conditions)

Female sexual dysfunction is also further categorized as lifelong (primary) or acquired (secondary—present for 6 mo or more). The updated classification system has a high rate of false negatives due to the elimination of individuals reporting mild-to-moderate symptoms. The symptoms must also cause significant distress to the individual. The change in criteria was established to avoid overmedicalization of normal sexual function.

SYNONYMS

Female sexual dysfunction
Hypoactive sexual desire disorder (HSDD)

ICD-10CM CODES (NOTE: The new classification categories will be included in the ICD-11)

R37	Sexual dysfunction, unspecified
F52.0	Hypoactive sexual desire disorder
F52.22	Female sexual arousal disorder
F52.31	Female orgasmic disorder
N94.1	Dyspareunia
N94.81	Vulvodynia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: According to the National Health and Social Life Survey, in 1999, ~20% to 50% of women reported some form of sexual dysfunction during their lifetimes. One third of women reported a decrease in sexual interest, and one fourth reported an inability to achieve orgasm.

PREVALENCE (TABLE E1): A more recent survey of women 18 yr of age and older found an age-adjusted prevalence of any sexual problem to be ~43%.

PREDOMINANT AGE: Sexually related personal distress was more common in middle-aged women (aged 45 to 64) than in younger or older women.

RISK FACTORS:

- Correlates of distressing sexual problems include poor self-assessed health, low education level, depression, anxiety, thyroid conditions, and urinary incontinence.
- Higher insomnia scores and shorter sleep duration are associated with decreased sexual function.
- Obesity and overweight body status have been associated with lower sexual satisfaction and desire.
- Comorbid conditions such as arthritis, diabetes mellitus, hypertension, malignancy, neuromuscular disorders, renal failure, and gynecologic (e.g., chronic pelvic pain) and dermatologic conditions (e.g., lichen sclerosis, psoriasis) can contribute to sexual dysfunction.
- Aging is associated with decreased sexual responsiveness, sexual activity, and libido.
- Decreased hormonal levels associated with menopause can cause decreased vaginal lubrication and dyspareunia.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History: Important to obtain the patient's definition of the dysfunction, including its onset and duration; to determine whether the dysfunction is situational or global; and to determine whether more than one dysfunction exists and the interrelationship among the dysfunctions. Dysfunction is diagnosed if the symptoms are causing distress to the patient.
- Related medical and gynecologic conditions (including prior gynecologic surgery)
- Psychosocial factors, including sexual abuse, sexual orientation, depression and anxiety, status of current relationships and sexual activity, personal and family beliefs about sexuality
- Current medications including OTC and herbal preparations; alcohol, tobacco, and drug use; and birth control method, substance use/misuse
- Physical examination:
  1. The gynecologic examination can aid in identifying signs of decreased estrogen and androgen levels, infection, endometriosis, pelvic floor dysfunction, and systemic disease
  2. Cotton swab test when concern exists for provoked vulvodynia
  3. Other body systems as indicated (e.g., cardiovascular, thyroid)

ETIOLOGY

- Chronic medical conditions (e.g., diabetes, coronary vascular disease, arthritis, urinary incontinence).
- Medication induced (e.g., antihypertensives, narcotics, hormonal preparations, antihistamines, amphetamines, psychotropic medications). SSRIs are the most common medications linked to sexual dysfunction.
- Gynecologic conditions (e.g., cystitis, posthysterectomy, gynecologic cancers, breast cancer [femininity/self-image issues; chemotherapy effects], postpregnancy, postmenopausal). Premenopausal BSO is associated with a higher risk of HSDD.

TABLE E1 Prevalence and Definition of Female Sexual Dysfunctions

	Prevalence*	Definition†
Hypoactive sexual desire/low libido	9%-60%	Diminished feelings of sexual interest or desire, absence of sexual thoughts, and/or lack of receptivity to sexual activity‡
Sexual arousal disorder/sex not pleasurable Difficulty with genital lubrication	5%-51% 8%-60%	**Genital Female Sexual Arousal Disorder (GFSAD)**: Disruption of clitoral erection, vaginal vasocongestion, vaginal lubrication **Psychological Female Sexual Arousal Disorder (PFSAD):** Absent or markedly diminished feelings of excitement or pleasure in response to sexual stimuli **Mixed Female Sexual Arousal Disorder:** GFSAD and PFSAD
Persistent genital arousal disorder	~1%	Persistent, recurrent, intrusive, and/or distressing sensations of genital arousal not related to sexual stimulation and that do not resolve after orgasm
Female orgasmic disorder	7%-65%	Lack of experience of orgasm or diminished orgasm intensity despite high sexual arousal after a period of sufficient sexual stimulation and arousal
Sexual pain disorders	4%-42%	**Dyspareunia**: Persistent/recurrent pain with attempted/complete vaginal entry with a penis, finger, or other object **Vaginismus:** Vaginal spasm or pain in response to penetration with a penis, finger, or other object despite a desire for penetration to occur‡
Anxiety about sexual performance	6%-16%	N/A

*Laumann et al, 1999; Nicolosi et al, 2005, 2006a, 2006b; Shifren et al, 2008; West et al, 2008; Witting et al, 2008; Garvey et al, 2009.
†Waldinger et al, 2009; Basson et al, 2010b.
‡The term *vaginismus* is no longer preferred, as it includes significant semantic baggage as a psychological disorder.

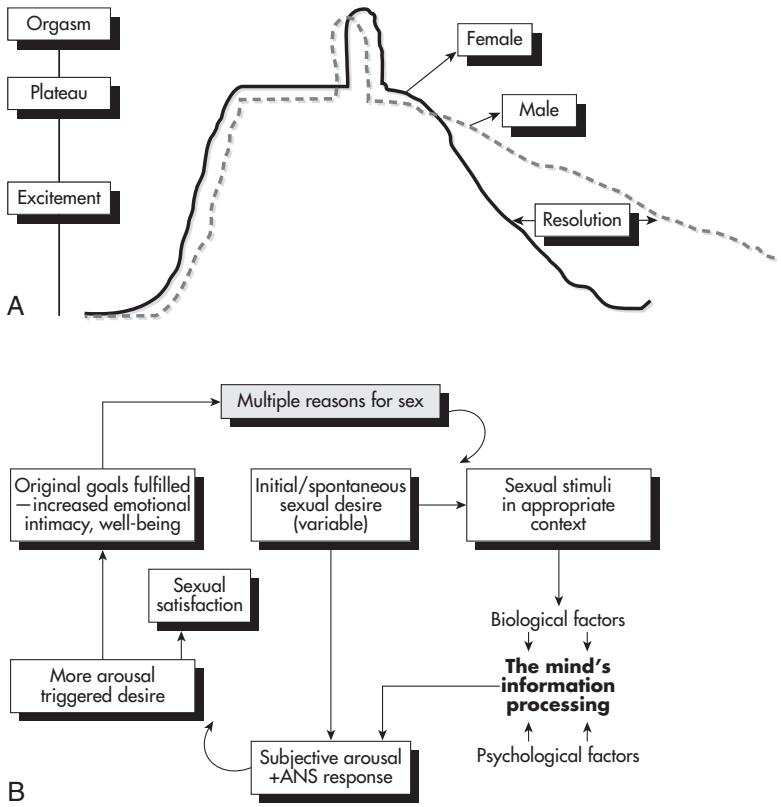

FIG. E1 A, The four phases of the human sexual response cycle as postulated by Masters and Johnson. Because the resolution phase is prolonged considerably in men, men can experience refractoriness to further stimulation for varying lengths of time before they can achieve another orgasm. As discussed in the text, understanding of the human sex response cycle has evolved substantially since the publication of this work. **B,** The circular human response cycle of overlapping phases. It is increasingly recognized that the human sexual response involves much more complexity, circularity, and flexibility than is reflected in Masters and Johnson's original model. "Desire" may or may not be present initially; it can be triggered during the experience. Arousal and desire overlap. Multiple psychologic and biologic factors influence the information processing of sexual stimuli. Underlying this processing may be the individual's unique tendency for excitation versus inhibition. *ANS,* Autonomic nervous system. (From Melmed S: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.)

- Psychosocial (e.g., religion, taboos, identity conflicts, guilt, relationship problems, abuse, rape, life stressors).
- Fig. E1 illustrates the four phases of the human sexual response as postulated by Masters and Johnson.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Depression
- Psychosocial stressors
- Medical disease (e.g., thyroid dysfunction)
- Menopausal status can be assessed using STRAW + 10 tool

LABORATORY TESTS

- Cervical cultures and vaginal swabs for infectious disease
- Cervical cancer screening as per current guidelines
- Appropriate laboratory tests if comorbid or chronic disease is suspected
- Measurement of prolactin, thyroid function tests, estrogen, progesterone, LH, testosterone, and sex hormone binding globulin is indicated only if a hormonal etiology is suspected from history

IMAGING STUDIES

Appropriate imaging studies if comorbid or chronic disease is suspected

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Treat genital arousal and pelvic pain symptoms before addressing HSDD
- Education including a discussion of normal sexual behavior
- Stress management
- Behavioral therapy (e.g., cognitive-behavioral therapy) and mindfulness-based interventions can treat low sexual desire and arousal disorders
- Counseling (individual or couples) for relationship issues
- Activities to enhance stimulation and eliminate routine
- Distraction techniques
- Noncoital behavior
- Position changes (e.g., female astride)
- Lubricants (e.g., nonpetroleum based). There are several over-the-counter lubricants and massage oils, some of which are hypoallergenic, that can be safely applied to female genitalia
- Physical therapy may be useful for patients with pelvic floor dysfunction and pain
- Eros clitoral therapy device: An FDA-approved device for targeting symptoms of FSAD

ACUTE GENERAL Rx

NSAIDs before intercourse for sexual pain disorders

CHRONIC Rx

- Treat underlying medical, gynecologic, or psychological conditions.
- Reduce comorbidities, including weight loss.
- Increase physical activity (associated with increased satisfaction and sexual engagement).
- For medication-induced conditions, decrease dose or change medication.
- For postmenopausal women or those with hypoestrogenism, try estrogen replacement therapy with or without progesterone. Local vaginal estrogen therapy is preferred over systemic therapy. Transdermal estradiol is superior to oral estradiol for improving sexual function because oral estradiol increases circulating sex hormone-binding globulin (SHBG) and lowers free testosterone, thus effecting libido adversely. Estrogen replacement is associated with improvements in dyspareunia and vaginal dryness.
- For postmenopausal vaginal and/or vulvar atrophy, ospemifene has been associated with improved sexual function.
- Transdermal testosterone therapy: Results show increase in satisfying sexual activity and sexual desire. Must weigh risks (hirsutism, acne, virilization, and cardiovascular complications) vs. benefits of use. Monitoring of testosterone levels to avoid supraphysiologic therapy is recommended.
- Sildenafil (evidence from RCTs for use in patients with neurodegenerative disease and antidepressant-induced FSD after traditional therapy has failed). Data are conflicting. Phosphodiesterase inhibitors may increase blood flow to the genitalia but generally appear to have little benefit in treating arousal disorders. Sildenafil has been helpful in patients with SSRI-induced sexual dysfunction.
- Bupropion 300 to 400 mg/day was shown to increase sexual arousal and orgasm completion in a recent trial. In addition, adjunctive treatment with bupropion significantly improved key aspects of sexual function in women with SSRI-induced sexual dysfunction.
- Flibanserin (Addyi): A nonhormonal treatment for HSDD. It is an agonist at serotonin 5-HT receptors and an antagonist at 5-HT_{2A} receptors. Its mechanism of action in treating HSDD is unknown. The recommended dose is

TABLE E2 Investigational Pharmacotherapy for Women's Sexual Dysfunctions

Sexual Dysfunction	Mechanisms of Dysfunction	Drug Type	Off-Label and Investigational Drugs	Comments
Sexual interest/ desire disorder	Loss of brain's arousability to sexual stimuli	Drugs with specific serotonin receptor subtype or agonist/ antagonist profile	Flibanserin: 5-HT1A agonist and 5-HT2A antagonist, weak partial D4 agonist	Flibanserin is now FDA approved for treatment of hypoactive sexual desire disorder
Subjective arousal disorder		Melanocortin agonists	Bremelanotide: Synthetic peptide, α-MSH analog agonist at MC1R, MC3R, MC4R	Small RCT showed benefit for women's arousal disorder with in-home use of nasal drug 45 min before sex. Sponsor has discontinued trials.
Combined arousal disorder		Dopamine agonists	Bupropion	One small 4-mo study in nondepressed premenopausal women showed increased arousability and sexual response, no increase in initial desire.
Genital arousal disorder: Estrogen deplete	Loss of genital vasocongestion in response to sexual stimulation	To provide local substrate for estrogen and testosterone intracrine synthesis	Local vaginal DHEA	Phase 3 RCT showed increased maturation of vaginal epithelium, lower pH, and sexual benefit in all domains of response from local vaginal DHEA for 12 wk.
		Selective tissue estrogenic activity regulator with androgenic and progestogenic properties	Tibolone	RCT of dysfunctional women showed tibolone marginally superior to 50 μg/140 μg combined transdermal estradiol/norethisterone. Major problem is distinguishing the subgroup of women with genital arousal disorder who have reduced genital vasocongestion. Small RCTs in diabetes and MS showed only modest benefit from sildenafil.
Genital arousal disorder despite estrogen replete	Loss of genital vasocongestion in response to sexual stimulation	To enhance the action of NO–PDEIs	Sildenafil, tadalafil, vardenafil	
Serotoninergic antidepressant–associated orgasmic disorder	Former orgasmic response absent or extremely delayed	PDEIs	Sildenafil	8-wk RCT with very strict entry criteria showed benefit from 50-100 mg sildenafil.

D4, Dopamine 4 receptor; *DHEA,* dehydroepiandrosterone; *5-HT,* serotonin; *ISSWSH,* International Society for the Study of Women's Sexual Health; *MC1R,* melanocortin-1 receptor; *MS,* multiple sclerosis; *MSH,* melanocyte-stimulating hormone; *NO,* nitric oxide; *PDEIs,* phosphodiesterase inhibitors; *RCTs,* randomized controlled trials.

100 mg once daily at bed time. Side effects include hypotension, syncope, and CNS depression. Consumption of alcohol increases risk of side effects and is contraindicated. It is mostly effective with approximately 10% of women reporting "much" or "very much" improvement in HSDD symptoms.

- Ospemifene: A selective estrogen receptor agonist/antagonist (SERM). Clinical trials demonstrated a significant improvement in sexual pain, arousal, and desire.
- Table E2 summarizes investigational pharmacotherapy for women's sexual dysfunctions.

REFERRAL

- Gynecologic referral for conditions that may be amenable to surgical therapy (e.g., pelvic floor disorders)
- Psychological referral for conditions (e.g., depression, abuse) that may benefit from counseling or psychotherapy
- Social services referrals for active abuse issues

BASIC INFORMATION

DEFINITION

Shaken baby syndrome is a potentially life-threatening and severe form of abuse in which an infant or child is violently shaken. Intracranial injury is caused by rapid acceleration and rotation of the cranium (sometimes associated with impact on a solid object which leads to rapid angular deceleration). The classic injury pattern associated with shaking includes diffuse subdural hemorrhage, retinal hemorrhages, and diffuse brain injury (Fig. E1). The diagnosis is often difficult to make because the clinical manifestations are nonspecific, perpetrators are unlikely to report a history of trauma, and there may be little to no external signs of injury.

SYNONYMS

Shaken infant syndrome
Abusive head trauma
Nonaccidental head injury

ICD-10CM CODES	
T74.1	Physical abuse
T74.4	Shaken infant syndrome, initial encounter
T74.4XXD	Shaken infant syndrome, subsequent encounter
T74.4XXS	Shaken infant syndrome, sequela

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Most common cause of death or serious neurologic injury resulting from child abuse. It is specific to infancy, when children have unique anatomic features. A population-based study conducted in the U.S. showed an incidence of abusive head trauma in children <2 yr of 17 per 100,000 persons with a higher incidence in the first yr of life compared to the second. Population-based studies in Europe show similar incidence in the first yr.

FIG. E1 Shaken baby syndrome. A, Facial bruising. **B,** Fundus hemorrhages involving different levels. (Courtesy R. Bates. From Kanski JJ, Bowling B: *Clinical ophthalmology, a systematic approach,* ed 7, Philadelphia, 2010, Saunders.)

PEAK INCIDENCE: Shaken babies are typically younger than 1 yr; with median age of 4 mo.
PREVALENCE: ~25% of clinically diagnosed babies with shaken baby syndrome die, and ~80% of the remaining suffer lifelong neurologic damage.
PREDOMINANT SEX: About 60% of identified victims of shaking injury are male. Children of families who live at or below the poverty level are at an increased risk for these injuries as well as any type of child abuse.
RISK FACTORS: History of abuse, history of domestic violence, low socioeconomic status, perinatal illness, incessant crying, and family dysfunction. The perpetrators in 65% to 90% of cases are males and are most commonly the father.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

In several retrospective series, no history of a traumatic event was offered in 64% to 97% of cases. One study of 364 children with shaken baby syndrome found that 40% had no signs of external injury on initial evaluation. Majority will have an abnormal neurologic examination. Generally present with nonspecific symptoms (i.e., seizures, failure to thrive, vomiting associated with lethargy or drowsiness, decreased feeding, hypothermia, bradycardia, hypertension or hypotension, respiratory irregularities, apnea, coma, or death). Retinal and cranial hemorrhages and brain injury are hallmarks of the syndrome. Other signs of abuse such as skull fractures, occult fractures (particularly of ribs and long bone diaphysis), abdominal injury, and hearing loss, may be present.

ETIOLOGY

Angular deceleration forces cause primary parenchymal injury including traumatic axonal injury. Neuropathology and imaging techniques have established the cause of brain injury as hypoxic ischemic encephalopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Head trauma from other etiology vs. infection vs. bleeding disorder vs. other etiology

WORKUP

Imaging of the brain, skeletal survey

LABORATORY TESTS

CBC, chemistry, coagulation study, lumbar puncture if meningitis is considered

IMAGING STUDIES

Initial study of unenhanced CT scan and skeletal survey. MRI should be done as follow up in patients with abnormal CT findings and is indicated for infants who are asymptomatic but require neuroimaging after finding noncranial injuries.

TREATMENT

Treatment focused on targeting specific injuries and also on prevention of future injuries.

NONPHARMACOLOGIC THERAPY

Admission to a hospital for observation

ACUTE GENERAL Rx

Supportive care and interventions as dictated by the clinical, laboratory, and imaging findings

CHRONIC Rx

Counseling, working with the child's school to optimize academic development

REFERRAL

Neurologist and neurosurgery (if needed)

PEARLS & CONSIDERATIONS

PREVENTION

The National Center on Shaken Baby Syndrome offers a prevention program. Additionally, researchers like Harvey Karp have suggested ideas.

PATIENT & FAMILY EDUCATION

Shaken baby syndrome can result in lifelong, irreversible injuries. Prevention is a key component. Infants crying most commonly leads to shaking. Therefore the National Center on Shaken Baby Syndrome offers a prevention program, the **Period of Purple Crying,** which seeks to help parents and other caregivers understand crying in normal infants. By defining and describing the sometimes inconsolable infant crying that can sometimes cause stress, anger, and frustration in parents and caregivers, the program hopes to educate and empower people to prevent abusive head trauma.

Another method that may help is one suggested by author Dr. Harvey Karp's "five S's":

1. Shushing: Use "white noise" or rhythmic sounds that mimic the constant whir of noise in the womb.
2. Side/stomach positioning: Place the baby on the left side to help digestion.
3. Sucking: Let the baby breast-feed or bottle-feed, or give the baby a pacifier or finger to suck on.
4. Swaddling: Wrap the baby up snugly in a blanket to help him or her feel more secure.
5. Swinging gently: Rock in a chair, use an infant swing, or take a car ride to help duplicate the constant motion the baby felt in the womb.

AUTHOR: **Fred F. Ferri, MD**

Sheehan Syndrome

BASIC INFORMATION

DEFINITION

Sheehan syndrome is a state of postpartum hypopituitarism resulting from infarction of the pituitary secondary to postpartum hemorrhage or shock. The enlarged pituitary gland in pregnancy is more susceptible to ischemia following hemorrhage and severe hypotension, causing partial or complete loss of the anterior pituitary hormones (adrenocorticotropic hormone [ACTH], follicle-stimulating hormone [FSH], luteinizing hormone [LH], growth hormone [GH], prolactin [PRL], thyroid-stimulating hormone [TSH]) and their target organ functions.

ICD-10CM CODES

E23.0 Hypopituitarism
E23.6 Other disorders of pituitary gland
E23.7 Disorder of pituitary gland, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Approximately 1 case in 10,000 deliveries. Actual frequency is not known but is thought to be higher in developing countries.
PREDOMINANT SEX: Affects only females
RISK FACTORS:

- Hypovolemic shock
- Type 1 (insulin-dependent) diabetes mellitus (secondary to microvascular disease)
- Sickle cell anemia (secondary to occlusion of the small vessels in the pituitary)
- Presence of small sella

ONSET OF SYMPTOMS: Symptoms may be acute or chronic. The severity of the disease depends on the extent of the damage to particular pituitary gland cell types. In the acute form, severe symptoms occur immediately postpartum, although this is rare. Chronic symptoms may appear months to yr after the initial insult.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Failure to lactate or difficulty with lactation
- Failure to resume menses after delivery
- Failure of axillary or pubic hair growth
- Diminished libido
- Infertility
- Skin depigmentation (including areola)
- Breast atrophy
- Vaginal atrophy causing pain with intercourse
- Superinvolution of the uterus
- Hypothyroidism (cold intolerance, dry skin, fatigue, weight gain, constipation)
- ACTH insufficiency (fatigue, chronic hypotension)
- Diabetes insipidus (rare)

ETIOLOGY

- Compromise of the blood supply to the low-pressure pituitary sinusoidal system may occur with postpartum hemorrhage or shock, resulting in pituitary infarct and/or necrosis.
- The extent of damage to pituitary determines the severity of resulting hormonal dysfunction.
- Antibodies against hypothalamic and/or pituitary cells have been reported, suggesting an autoimmune cause.
- Severity of postpartum hemorrhage does not always correlate with the presence of Sheehan syndrome. Although rare, Sheehan syndrome has also been reported with normal postpartum bleeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Postpartum autoimmune hypophysitis
- Chronic infections
- HIV
- Sarcoidosis
- Amyloidosis
- Rheumatoid disease
- Hemochromatosis
- Metastatic carcinoma
- Lymphocytic hypophysitis
- Pituitary tumor

WORKUP

- Target gland deficiency should be investigated by measuring levels of ACTH, FSH, LH, TSH (which may be normal or low), and T_4. Cortisol and estradiol (which may be low) should also be measured.
- Provocative testing of pituitary hormone reserves (e.g., metyrapone test, insulin tolerance test, and cosyntropin test): Normal, subnormal, or delayed responses may suggest the presence of islands of pituitary cells that no longer have the support of the hypothalamic-portal circulation.
- Measurement of insulin-like growth factor-1 to screen for GH deficiency: Subnormal levels suggest decreased GH.
- Impaired prolactin response to TRH or dopamine antagonist stimulation is frequently found.
- During pregnancy, adjustments must be made in interpreting both hormone levels and responses to various stimuli because of normal physiologic changes.

IMAGING STUDIES

- MRI of the pituitary:
  1. Early findings: Enlarged enhancing pituitary
  2. Late findings: Empty sella
  3. Rules out mass lesion
- CT scan of the pituitary when MRI is unavailable or contraindicated

TREATMENT

ACUTE GENERAL Rx

- Early identification and treatment are essential. Clinicians should have a high index of suspicion with any woman experiencing related symptoms following postpartum hemorrhage and/or shock.
- Acute form can be lethal, presenting with hypotension, tachycardia, failure to lactate, and hypoglycemia.
- IV corticosteroids and fluid replacement should be given initially.
- Diagnosis is confirmed with a full endocrinologic workup.
- Treatment involves replacement of deficient pituitary hormones such as corticosteroids, levothyroxine, estrogen, and growth hormone.

CHRONIC Rx

- With late-onset disease (symptoms of general hypopituitarism, such as oligomenorrhea or amenorrhea, vaginal atrophic changes, and loss of libido): A full endocrinologic workup and replacement of the appropriate hormones are needed.
- With symptoms of adrenal insufficiency: Corticosteroids should be given.
  1. A maintenance dose of cortisone acetate or prednisone may be given.
  2. Adrenal production of cortisol is not entirely dependent on ACTH; thus, replacement of mineralocorticoids is rarely necessary.
  3. Stress doses of glucocorticoids should be administered during surgery or during labor and delivery.

DISPOSITION

- Patients who receive early diagnosis and adequate hormonal replacement may expect favorable outcomes, including subsequent pregnancy.
- Central adrenal insufficiency is the primary cause of mortality in Sheehan syndrome.

REFERRAL

Patients should have yearly examinations by an endocrinologist.

Shift Work Disorder

BASIC INFORMATION

DEFINITION

- Shift work refers to nonstandard work schedules, including permanent or intermittent night work, early morning work, and rotating schedules.
- Shift work disorder (SWD) is defined as the development of sleep disturbances and impairment of waking alertness and performance that some, but not all, individuals experience when adapting to shift work.

SYNONYMS

Circadian rhythm sleep disorder of shift work type
SWD

ICD-10CM CODE
G47.26. Circadian rhythm sleep disorder, shift work type

EPIDEMIOLOGY & DEMOGRAPHICS

- The disorder is caused by the patient working at a time when his/her circadian rhythm is trying to initiate and maintain sleep.
- It is not known why some people are more resilient to the effects of shift work than others.
- Most people will have some difficulty tolerating shift work and may benefit from the same interventions as those with more significant problems associated with SWD.

INCIDENCE: Not known
PEAK INCIDENCE: Not known
PREVALENCE:

- Prevalence of SWD is difficult to estimate because the boundary between a "normal response" to night work, and a diagnosable disorder is not sharp.
- Approximately 16% to 20% of the total work force is engaged in night-shift work. Survey data suggest that 5% to 10% of all shift workers experience clinically significant problems that would warrant a diagnosis of SWD.

PREDOMINANT SEX AND AGE: More prevalent in shift workers aged above 50 yr and worsens with passage of time if the work hours persist.
GENETICS: No known genetic contribution to SWD
RISK FACTORS: SWD is more likely in shift workers who have a morning-type disposition, sleep need greater than 8 hours, or strong competing social and/or personal demands (e.g., child rearing).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Diagnosis is based on history of the patient working outside 8:00 A.M. to 6:00 P.M. daytime window on a regular basis.
- Sleep logs and actigraphy (devices that estimate sleep/wake schedule based on movement) can be helpful but are not required for the diagnosis.

ETIOLOGY

SWD is understood to be a circadian rhythm disorder primarily caused by exogenously determined alterations in the timing of sleep and wakefulness rather than disturbances of the endogenous circadian rhythm itself.

DIAGNOSIS

Diagnostic criteria include persistent sleep disruption that leads to excessive sleepiness or difficulty sleeping or both. The sleep disturbance causes clinically significant distress or impairment and problems occur as a result of shift work schedule. Diagnostic criteria for SWD are summarized in Table E1.

DIFFERENTIAL DIAGNOSIS

- Normal variations in sleep with shift work (e.g., short-term or mild difficulties adjusting to new shift)
- Insomnia disorder (sleep problems not specifically linked to shift work)
- Other circadian rhythm disorder (e.g., jet lag, free running disorder)
- Sleep apnea (a common comorbidity that can make shift work more difficult)

WORKUP

- Ideally, SWD is assessed by clinical interview, supplemented with sleep logs and actigraphy. Actigraphy is the estimation of sleep and wake times based on movement. Several medical-grade devices are available that have been validated in relation to polysomnography (the gold standard for sleep assessment).
- Clinical interview should address difficulties with performance during night shift, problems sleeping during the day, and assess other sleep, psychiatric, and medical conditions that can co-occur with SWD and exacerbate symptoms (see Differential Diagnosis earlier).

LABORATORY TEST

Polysomnography (i.e., a comprehensive, in-lab sleep study) is usually not necessary in diagnosis or treatment of SWD but may be helpful for ruling out other sleep disorders with overlapping symptoms.

TREATMENT

SWD requires behavioral changes to minimize impact of scheduling on sleep and circadian biology. Pharmacological interventions must be carefully timed in order to be most beneficial. Table E2 summarizes clinical guidelines for assessment and management of SWD.

NONPHARMACOLOGIC THERAPY

- Planned naps before night shifts improve performance without compromising sleep after shift has ended. Planned naps during shifts can also be helpful when feasible, but workers can be impaired immediately after awakening.

TABLE E1 Diagnostic Criteria for Shift Work Disorder

***International Classification of Sleep Disorders* (ICSD3) Criteria: General Criteria for Any Circadian Rhythm Sleep-Wake Disorder**

A. A chronic or recurrent pattern of sleep-wake rhythm disruption due primarily to alteration of the endogenous circadian timing system or misalignment between the endogenous circadian rhythm and the sleep-wake schedule desired or required by the person's physical environment or social/work schedules.
B. The circadian rhythm disruption leads to insomnia symptoms, excessive sleepiness, or both.
C. The sleep and wake disturbances cause clinically significant distress or impairment in mental, physical, social, occupational, educational, or other important areas of functioning.

Specific Criteria for Circadian Rhythm Sleep-Wake Disorder, Shift Work Disorder (ICD-9-CM code: 327.36)*

A. There is a report of insomnia and/or excessive sleepiness, accompanied by a reduction of total sleep time, which is associated with a recurring work schedule that overlaps the usual time for sleep.
B. The symptoms have been present and associated with the shift work schedule for at least 3 mo.
C. Sleep log and actigraphy monitoring (whenever possible and preferably with concurrent light exposure measurement) for at least 14 days (work and free days) demonstrate a disturbed sleep and wake pattern.
D. The sleep and/or wake disturbance are not better explained by another current sleep disorder, medical or neurologic disorder, mental disorder, medication use, poor sleep hygiene, or substance use disorder.

Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition: DSM-5*: Diagnostic Criteria for Circadian Rhythm Sleep Disorder (307.45)

A. A persistent or recurrent pattern of sleep disruption that is due primarily to an alteration of the circadian system or to a misalignment between the endogenous circadian rhythm and the sleep-wake schedule required by the person's physical environment or social or professional schedule.
B. The sleep disruption leads to excessive sleepiness or insomnia, or both.
C. The sleep disturbance causes clinically significant distress or impairment in social, occupational, and other important areas of functioning.

Specify Type:

Shift work type: Insomnia during the major sleep period and/or excessive sleepiness (including inadvertent sleep) during the major awake period associated with a shift work schedule (i.e., recurring unconventional work hours).

*ICD-10CM code: G47.26 circadian rhythm sleep-wake disorder, shift work type.
ICD-9-CM: International Classification of Diseases, Ninth Revision, Clinical Modification.
From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.

TABLE E2 Clinical Guidelines for Assessment and Management of Shift Work Disorder

Assessment

I. Determine circadian misalignment (sleep diaries and actigraphy with concurrent light exposure).
II. Assess sleep disturbance.
  A. Determine difficulty falling asleep, staying asleep, or having nonrestorative sleep (both during daytime and nighttime sleeps).
  B. Measure degree of alertness.
  C. Assess falling asleep during inappropriate circumstances or times (using Epworth Sleepiness Scale [ESS]), with special attention to drowsy driving.
  D. Determine important job-related factors: Duration of commute after shift, number of consecutive shifts, type of shift, time between shifts.
III. Determine impact on social and domestic responsibilities.[1]

Management[2]

I. Shift workers should have regular physical examinations with attention to psychological (e.g., depression), gastrointestinal, cardiovascular, and potential cancer risks associated with shift work.[2]
  A. Sleep-related comorbidity: Determine risk of sleep-disordered breathing, restless legs syndrome, or other potential sleep disorder.
  B. Other comorbidity: Identify medical or psychiatric disorders that may contribute to the symptoms of insomnia or excessive sleepiness.
II. Determine if removal from shift work is appropriate or practically feasible. If patient meets criteria for a diagnosis of shift work disorder, cessation of the shift work schedule should be the first option discussed with the patient.
III. Determine patient-specific therapeutic approach.
  A. Circadian adaptation
    1. Consider individual difference factors (e.g., age, phase preference).
    2. Consider compromise phase position (e.g., partial phase delay using bright light during first half of night and increased darkness during daytime).
    3. *Night workers*: On days off, adopt a late sleep schedule (i.e., bedtime of 3:00 to 4:00 A.M.).
  B. Symptom management
    1. Insomnia
      a. Good sleep behaviors
        i. Target inappropriate sleep behaviors and encourage use of eye mask, ear plugs, and light-blocking shades during daytime sleep.
      b. Sleep maintenance a primary concern
        i. Consider intermediate-acting hypnotic (half-life of 5 to 8 hours).
        ii. Consider melatonin treatment for daytime sleep (~3 mg).
      c. Sleep initiation problems
        i. Consider short-acting hypnotic.
      d. Sleep problems on days off
        i. Consider fixed sleep-wake schedule and consider anchor sleep.
        ii. Excessive sleepiness (i.e., ESS score <10)
    2. Address sleep disturbance if present.
      a. Consider wake-enhancing medication before shift (e.g., modafinil, armodafinil) or off-label stimulants (e.g., amphetamine, methylphenidate).
      b. Prophylactic nap before work shift is recommended.
      c. Judicious use of brief to moderate-length naps (30 to 60 min), with recognition of risk of sleep inertia (consider prenap caffeine to reduce sleep inertia).
      d. Consider combined treatment strategies during the work shift (alerting medications, bright light, anchor sleep, and naps).
IV. Address additional work, social, and domestic factors.
  A. Social/family/psychological: Improve balance between family/social, work, and sleep time and treat psychosocial stress, depression, or marital discord if present,[1] educate patient's family regarding shift worker's need of protected time for sleep.
  B. Health and safety: Promote improved healthy eating habits with respect to regularity and timing relative to the major sleep period (not within 2 to 4 hours of bedtime), reduce inappropriate substance use, increase exercise at appropriate times (not within 2 to 4 hours of bedtime), educate on risks of drowsy driving and critical times of performance vulnerability.
  C. Work-related: Reduce number of consecutive shifts (<4),[1] reduce shift duration (<12 hours), use clockwise rotation,[3] ensure adequate time between shifts (>11 hours),[1] move heavy workload outside circadian nadir (4:00 to 7:00 A.M.), address commute time (longer = greater accident risk), move to day or evening shift,[4] consider incorporation of a shift work awareness program.[5]

[3]Monk TH: What can the chronobiologist do to help the shift worker? *J Biol Rhythms* 15:86-94, 2000.
[4]Pilcher JJ et al: Differential effects of permanent and rotating shifts on self-report sleep length: a meta-analytic review, *Sleep* 23:155-163, 2000.
[5]Monk TH, Folkard S: *Making shift work tolerable,* Boca Raton, 1992, CRC Press.
From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.

- Bright light during night shift work improves alertness. Both short- and long-duration light exposure has been shown to be helpful relative to normal lighting.
- Bright light should be avoided in the morning when feasible to protect daytime sleep. Darkened glasses can be helpful provided that they do not compromise driving ability (if shift worker must drive home after shift).
- Daytime sleep environment should be protected from both light and noise. Sleep masks, black-out curtains, ear plugs, and noise machines can be helpful.
- Circadian adaptation during jet travel is illustrated in Fig. E1.

ACUTE GENERAL Rx

- Wake-promoting medications such as modafinil/armodafinil, caffeine, and amphetamine have been shown to improve performance during the night shift. Modafinil and caffeine have established safety records and are generally considered as first-line treatments. Ideally, medications would be administered at times and doses where daytime sleep after the shift work is not affected.
- Hypnotic medications can be helpful for promoting daytime sleep after night shift work. Carryover sedation must be evaluated to ensure performance during night shift work is not impaired. Specific agents that have been tested include triazolam, temazepam, and zopiclone. Evidence is stronger for promoting sleep during day than improving waking performance during night shift work.
- Melatonin administered before daytime sleep (after night shift work) has been shown to be effective. Melatonin is not regulated by the FDA, and so it is important to avoid brands with poor performance in independent laboratory tests. Fig. E2 illustrates using light and melatonin to phase shift the internal biologic time.

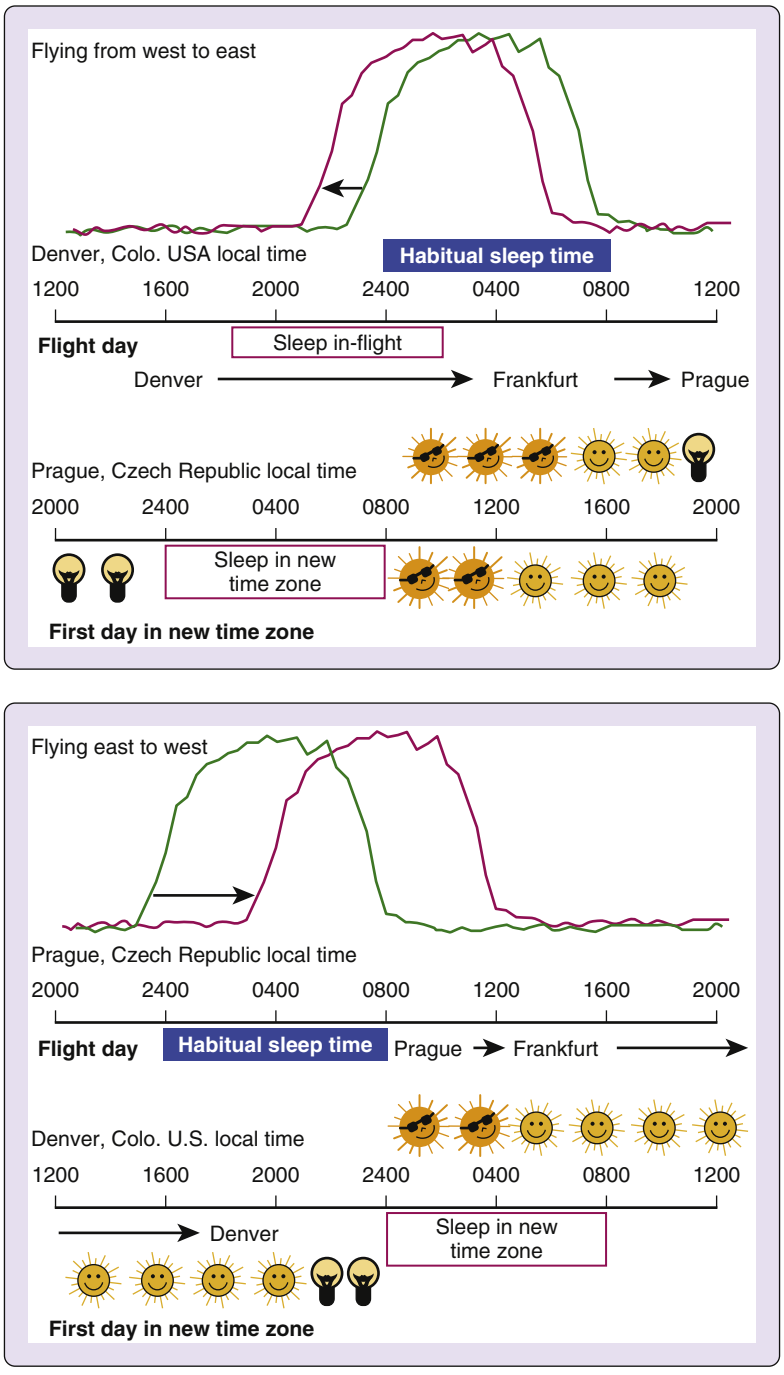

FIG. E1 Circadian adaptation during jet travel. *Top:* When traveling eastward, the jet traveler needs to advance the timing of his or her sleep schedule as well as the phase of the internal circadian clock so that both occur earlier. In the current example of a trip from Denver, Colorado, to Prague, Czech Republic, the primary plane flight to Frankfurt *(long black arrows)* occurs during the beginning of the biologic night, when endogenous melatonin levels are high *(green line; top panel).* The traveler should sleep as much as possible on the plane flight to reduce the negative impact of sleep deprivation during jet travel. Exogenous melatonin taken shortly after boarding the plane may help the traveler fall asleep earlier than normal when endogenous melatonin levels are low. In this example, the traveler spends several hours in Frankfurt before the flight connection to Prague. Light exposure during most of the biologic night will induce a westward phase delay, opposite to what is needed for an eastward shift; accordingly, the traveler should avoid exposure to bright light *(sun with sunglasses)* and wear an eye mask or sunglasses until after the habitual time of awakening in the home time zone. Subsequent exposure to bright light *(sun without sunglasses and light bulb)* will facilitate the eastward phase advance of the traveler's circadian clock *(red line; top panel).* Sleep timing should be consistent with the local time zone in Prague, and melatonin may again help phase shift the clock and promote sleep onset if taken when endogenous melatonin levels are low. The next day, the traveler should at first continue to avoid exposure to bright light. Each day, the time of exposure to bright light can be moved earlier by 1 to 2 hours per day. *Bottom:* When traveling westward, the jet traveler needs to delay the timing of his or her sleep schedule as well as the phase of the internal circadian clock *(green line; bottom panel)* so that both occur later. In the example of a trip from Prague to Denver, plane flights occur across the biologic day when endogenous melatonin levels are low, and the traveler should remain awake for much of the trip, assuming that sleep was adequate before travel. Caffeine and/or a nap can help to support subsequent wakefulness. Exposure to bright light should occur across the entire plane flight and until just before bedtime in the new time zone, to facilitate a westward phase delay *(red line; bottom panel).* (From Kryger M et al: *Principles and practice of sleep medicine*, ed 6, Philadelphia, 2017, Elsevier.)

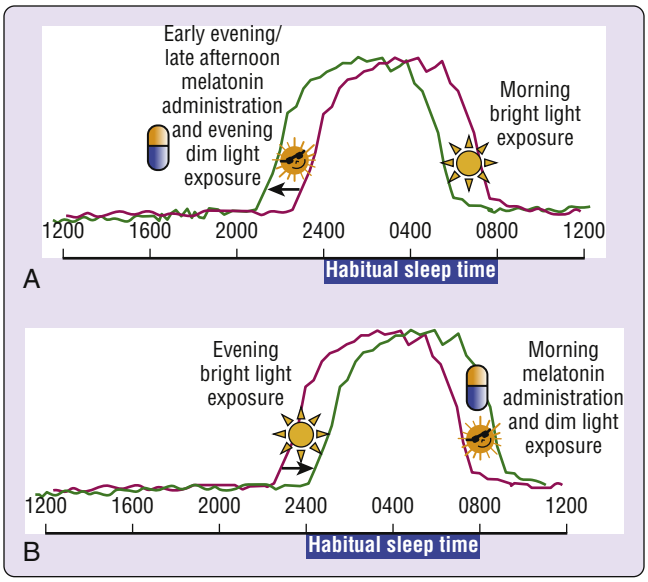

FIG. E2 Using light and melatonin to phase shift the internal biologic time. A, When the traveler is entrained to local time, light exposure during the morning and melatonin ingestion in the afternoon will induce an eastward phase advance shift of the internal circadian clock. *Red line* shows initial melatonin rhythm and *green line* shows advanced melatonin rhythm after treatment. **B,** Light exposure during the evening and melatonin administration in the morning will induce a westward phase delay shift of the internal circadian clock. *Red line* shows initial melatonin rhythm and *green line* shows delayed melatonin rhythm after treatment. Adjustment to eastward travel should include exposure to dim light or darkness in the evening. This can be achieved by wearing sunglasses if the sun has not set and by turning down the lights in the house. Adjustment to westward travel should include exposure to dim light or darkness in the morning. Administration of melatonin when the jet traveler is required to be awake (e.g., for work or driving) should be avoided, because melatonin has been reported to impair performance. (From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.)

CHRONIC Rx

Patients with chronic difficulty adapting to shift work despite adequate treatment may need to find other work. Many shift work jobs can be dangerous if completed by individuals who are impaired by sleepiness.

COMPLEMENTARY & ALTERNATIVE MEDICINE

No evidence-based recommendations currently available

REFERRAL

- Sleep medicine specialists in pulmonology, neurology, or psychiatry generally have expertise to treat SWD.
- Psychologists specializing in behavioral sleep medicine can be consulted (where available).

PEARLS & CONSIDERATIONS

COMMENTS

- Most people who work night shifts will experience difficulties and can benefit from treatment strategies for SWD.
- All shift workers should be educated about dangers associated with working while impaired by sleep deprivation.
- Co-occurring sleep disorders, especially sleep apnea, are common and can exacerbate symptoms of SWD. All shift workers should be screened for sleep disorders.
- When possible, inconsistent shifts and rotating schedules should be avoided.
- Treatment strategies are designed around delaying circadian rhythms as much as possible, then providing countermeasures for fatigue during shift, and protecting or promoting sleep during the day.

PREVENTION

SWD can be prevented by avoiding night shift work. However, many essential services require night shift workers. Early detection and treatment for mild SWD is essential. Those with more severe SWD may need to consider working earlier shifts.

PATIENT & FAMILY EDUCATION

The National Sleep Foundation (sleepfoundation.org) provides high-quality information on SWD and ways to manage symptoms.

RELATED TOPIC

Insomnia (Related Key Topic)

AUTHOR: **Jared D. Minkel, PhD**

Shigellosis PTG

BASIC INFORMATION

DEFINITION

Shigellosis is an inflammatory disease of the bowel caused by one of four species of *Shigella.* It is the third most common cause of diarrhea in the United States after *Salmonella* and *Campylobacter* and the most common cause of bacillary dysentery in the United States.

SYNONYM

Bacillary dysentery

ICD-10CM CODES

A03.9	Shigellosis, unspecified
A03.0	Shigellosis due to *Shigella dysenteriae*
A03.1	Shigellosis due to *Shigella flexneri*
A03.2	Shigellosis due to *Shigella boydii*
A03.3	Shigellosis due to *Shigella sonnei*
A03.8	Other shigellosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 6.59 cases per 100,000 population with approximately 450,000 cases/yr

PREDOMINANT SEX: Male homosexuals are at increased risk.

PREDOMINANT AGE: Shigellosis predominantly affects children (Box E1), with 28 cases per 100,000 population in children <4 yr old and 25.67 cases per 100,000 population in children aged 4 to 11.

PEAK INCIDENCE: Summer

GENETICS: Neonatal infection: Rare but severe

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Possibly asymptomatic, but incubation period can range from 1 to 7 days with an average of 3 days
- Mild illness that is usually self-limited, resolving in a few days
- High fever
- Watery diarrhea. Dysentery (abdominal cramps, tenesmus, and numerous, small-volume stools with blood, mucus, and pus)
- Descending intestinal tract illness, reflecting infection of small bowel first and then the colon
- Severe disease is more common in children and elderly and outside of the U.S.

BOX E1 Risk Factors for Severe Disease

Infants, and adults >50 yr
Children who are not breastfed
Children recovering from measles
Patients with HIV
Malnourished children and adults
Any patient who develops dehydration, unconsciousness, hypothermia, or hyperthermia, or has a history of convulsion

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

- Complications of severe illness (Box E2):
  1. Seizures
  2. Megacolon
  3. Intestinal perforation
  4. Death
- Extraintestinal manifestations are uncommon (reactive arthritis in up to 3% of patients)
- Bacteremia is more common in children; in adults it has been described in patients with AIDS, the elderly, and diabetics
- Hemolytic-uremic syndrome (HUS): Can be caused by *S. dysenteriae*
- Reactive arthritis, sometimes as part of Reiter syndrome following *S. flexneri* infection

ETIOLOGY

- *Shigella:* Gram-negative rod bacteria that are less susceptible to stomach acid and thus as few as 10 to 100 bacteria can cause disease. The bacteria invade colonic tissue and cause inflammation.
  1. *S. flexneri.*
  2. *S. dysenteriae.*
  3. *S. sonnei.*
  4. *S. boydii.*
- *S. sonnei* is the most commonly isolated species in the United States (over 75% of cases), and it usually causes a mild, watery diarrhea.
- Direct person-to-person transmission by consumption of contaminated food or water is thought to be the most common route. Outbreaks among men who have sex with men have occurred because of direct or indirect oral-anal contact.
- Contaminated food or water may transmit disease.
- Outbreaks have occurred in day care centers, a community wading pool frequented by toddlers, and residential institutions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- May mimic other bacterial gastroenteritis, such as *Clostridium difficile, Salmonella, Campylobacter,* and *Yersinia.*
- Dysentery can also be caused by *Entamoeba histolytica.*
- Bloody diarrhea may resemble disease caused by invasive *E. coli* (IEC).
- Hemolytic-uremic syndrome caused by enterohemorrhagic *E. coli* (O157:H7).

LABORATORY TESTS

- The diagnosis is established by bacterial stool culture.
- Stool should be cultured from fresh samples, because the yield is increased by processing the specimen soon after passage. The best yield is from the mucoid part of the stool.
- Serology is available but rarely useful.
- Polymerase chain reaction (PCR) is available but due to cost used mainly for outbreak investigations.
- Fecal leukocyte preparation may show WBCs.
- Total WBCs may be low, normal, or high. Leukemoid reactions can occur in children.
- Blood cultures should be obtained in patients with severe disease or sepsis syndromes.

IMAGING STUDIES

Abdominal radiographs may suggest megacolon or perforation in rare, severe cases.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Adequate hydration
- Electrolyte replacement

BOX E2 Complications of Shigellosis

Abdominal
- Persistent diarrhea
- Postdysenteric irritable bowel syndrome
- Ileus, toxic megacolon, intestinal perforation
- Protein-losing enteropathy, malnutrition
- Surgical complications: Intestinal perforation and obstruction, appendicitis, intraabdominal abscesses

Neurologic
- Seizures
- Headache, lethargy, disorientation, hallucinations
- Coma
- Severe toxin encephalopathy or ekiri syndrome

Bacteremia
- In malnourished children, young infants, and HIV-AIDS patients

Hemolytic-Uremic Syndrome
- Only with *Shigella dysenteriae* serotype 1

Urogenital
- Vulvovaginitis, urinary tract infections

Other
- Conjunctivitis, keratitis, corneal ulcers
- Reactive arthritis
- Reiter syndrome
- Hepatitis
- Myocarditis

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

ACUTE GENERAL Rx

Antibiotics recommended in all patients with positive stool cultures, severe illness, immunocompromised status:

- To shorten course of illness.
- To limit transmission of illness.
- For adults: Pending susceptibilities, ciprofloxacin 750 mg PO bid for 3 days or levofloxacin 500 to 750 mg q day for 3 days should be used. An alternative is azithromycin 500 mg q day for 3 days.
- For children: IV ceftriaxone (50 mg/kg/day) for 5 days in cases of severe disease. For oral therapy, can use cefixime: 8 mg/kg/day as single daily dose or divided q12h for 5 days *or* azithromycin: 10 mg/kg/day in a single daily dose for 3 days. A short course of an oral quinolone can also be used safely although they are not approved for children.

DISPOSITION

- Most disease is self-limited and resolves without treatment.
- Severe illness may be fatal.

REFERRAL

For severe illness or complications

PEARLS & CONSIDERATIONS

COMMENTS

- Shigella is one cause of "gay bowel syndrome."
- Illness is worsened by agents that decrease intestinal motility.
- Food handlers, child care providers, and health care workers should have a negative stool culture documented following treatment.

Short Bowel Syndrome ALG PTG

BASIC INFORMATION

DEFINITION

Short bowel syndrome (SBS) is a malabsorption syndrome that results from extensive small intestinal resection or congenital causes (Table 1).

SYNONYMS

Short bowel
SBS

ICD-10CM CODE
K91.2 Postsurgical malabsorption, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

- Parallels Crohn disease (see "Crohn Disease" in Section I), which is the most common cause of the syndrome in adults.
- In children, two thirds of short bowels are related to congenital abnormalities (intestinal atresia, gastroschisis, volvulus, aganglionosis) and one third are related to necrotizing enterocolitis.
- Prevalence: 10,000 to 20,000 cases are estimated to exist in the U.S.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Diarrhea and steatorrhea
- Weight loss
- Anemia related to iron or vitamin B_{12} absorption
- Bleeding diathesis related to vitamin K malabsorption
- Osteoporosis/osteomalacia related to vitamin D and calcium malabsorption
- Hyponatremia, hypokalemia
- Hypovolemia
- Other macronutrient or micronutrient deficiency states

ETIOLOGY

- Extensive bowel resection for treatment of the conditions mentioned previously (see "Epidemiology"). SBS typically does not occur until less than 200 cm of healthy small intestine remains. Risk for SBS is decreased if colon is intact.
- Congenital.
- Box 1 summarizes causes of short bowel syndrome.

The human intestine is 3 to 8 m in length. Removal of up to half of the small intestine produces no disruption in nutrient absorption, and most patients can maintain nutritional balance on oral feeding if they have more than 100 cm (3 ft) of jejunum. Similarly, 100 cm of intact jejunum can maintain a normal water, sodium, and potassium balance under normal circumstances. The presence of an intact colon can compensate for some small intestine loss.

Site-specific functions (Fig. 1):

- Calcium, magnesium, phosphorus, iron, and vitamins are absorbed in the duodenum and proximal jejunum.
- Vitamin B_{12} and bile acids are absorbed in the ileum. The resection of more than 60 cm of ileum results in vitamin B_{12} malabsorption. The loss of more than 100 cm results in fat malabsorption (from the loss of bile acids).
- The loss of gastrointestinal endocrine hormones can affect intestinal motility.
- Intestinal bacterial overgrowth may also occur, especially if the ileocecal valve is lost.

BOX 1 Causes of Short Bowel Syndrome (SBS) and Intestinal Failure in Adults and Children

Adults
Catastrophic vascular accidents:
  Superior mesenteric arterial embolism
  Superior mesenteric arterial thrombosis
  Superior mesenteric venous thrombosis
Chronic intestinal pseudoobstruction
Intestinal resection for tumor or trauma
Midgut volvulus
Multiple intestinal resections for Crohn disease
Radiation enteritis
Refractory sprue
Scleroderma and mixed connective tissue disease

Children
Congenital villus atrophy
Extensive aganglionosis
Gastroschisis
Jejunal or ileal atresia
*Necrotizing enterocolitis

*Functional SBS can also occur in conditions associated with severe malabsorption and intact bowel length.

From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

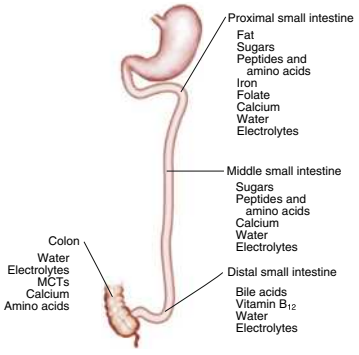

FIG. 1 Specific areas of absorption of dietary constituents and secretions in the small intestine and colon. Macronutrients and micronutrients are absorbed predominantly in the proximal jejunum. Bile acids and vitamin B_{12} (cobalamin) are absorbed only in the ileum. Electrolytes and water are absorbed in both the small and large intestine. Medium-chain triglycerides *(MCTs),* calcium, and some amino acids can be absorbed in the colon. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

- Macronutrient requirements in patients with short bowel syndrome are summarized in Table 2.

DIAGNOSIS

Presence of macronutrient and/or micronutrient loss in a patient with a known history of bowel resection. Daily stromal or fecal losses of electrolytes, minerals, and trace elements in SBS are summarized in Table 1.

DIFFERENTIAL DIAGNOSIS

Because the history of significant bowel resection is typically known, there is no differential diagnosis. If that history is not known, all causes of weight loss, malabsorption, and diarrhea must be considered.

TREATMENT

Extensive small bowel resection with colectomy (<100 cm of jejunum):

- Rx: Long-term total parenteral nutrition (TPN). Some patients can switch to oral intake after 1 to 2 yr of TPN. In jejunostomy patients, excessive fluid loss can be reduced with H_2 blockers, proton pump inhibitors, or octreotide. Micronutrients are supplemented.

Extensive small bowel resection with partial colectomy (usually patients with Crohn disease):

- Rx: Oral intake alone is possible in all patients with >100 cm of jejunum. In addition to vitamin B_{12} deficiency, these patients often have diarrhea. Consider lactose malabsorption and bacterial overgrowth treated, respectively, with lactose restriction and antibiotics (tetracycline 250 mg tid or metronidazole 500 mg tid for 2 wk). Nonspecific antidiarrheal agents may also be indicated (e.g., Imodium or codeine). The patient must be monitored for micronutrient losses.
- Table 3 and Fig. 2 summarize management strategies for SBS. Intestinal transplantation is performed mostly in children at selective centers.
- Therapeutic agents used to decrease intestinal transit and diarrheal volume are summarized in Table E4.
- FDA-approved medications for SBS in patients receiving nutritional support are:
  1. Recombinant growth hormone somatropin (Zorbtive): Effective in increasing weight and reducing parenteral nutrition volume. These effects do not persist when the drug is stopped.
  2. Teduglutide (Gattex), a recombinant DNA analog of glucagon-like peptide-2. It promotes mucosal growth in the small bowel through stimulation of crypt cell proliferation and inhibition of enterocyte apoptosis. This drug may have to be continued indefinitely for effects to persist.

COMPLICATIONS

- Oxalate kidney stones
- Cholesterol gallstones
- D-Lactic acidosis

TABLE 1 Daily Stomal or Fecal Losses of Electrolytes, Minerals, and Trace Elements in Severe Short Bowel Syndrome*

Component	Amount Lost
Sodium	90-100 mEq/L
Potassium	10-20 mEq/L
Calcium	772 (591-950) mg/day
Magnesium	328 (263-419) mg/day
Iron	11 (7-15) mg/day
Zinc	12 (10-14) mg/day
Copper	1.5 (0.5-2.3) mg/day

*For sodium and potassium, the average concentration per liter of stomal effluent is given. Values for minerals and trace elements are mean 24-hour losses, with the range in parentheses.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE 2 Macronutrient Requirements in Patients with Short Bowel Syndrome

Colon Present	Colon Absent
Carbohydrate	
Complex carbohydrates/starches	Variable types
30-35 kcal/kg per day	30-35 kcal/kg per day
Soluble fiber	
Fat	
MCT/LCT	LCT
20%-30% of caloric intake	20%-30% of caloric intake
Protein	
Intact protein	Intact protein
1.0-1.5 g/kg per day	1.0-1.5 g/kg per day

LCT, Long-chain triglycerides; *MCT,* medium-chain triglycerides.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TABLE 3 Management Strategies for Short Bowel Syndrome

1. Acute phase
   a. Treat postoperative complications
   b. Maintain full support via the parenteral route
   c. Initiate low-rate trophic enteral feeds
   d. Document amount and site of remaining bowel and underlying disease
2. Early adaptation (up to 1 yr postsurgery)
   a. Increase enteral nutrition to tolerance; supplement with glutamine
   b. Achieve permanent parenteral access, if indicated
   c. Maximize antiperistaltic agents
   d. Octreotide for high-output ostomy or fistula
   e. Dietary counseling
   f. Clinical trials of trophic growth factors
3. Long-term adaptation (>1 yr postsurgery)
   a. Recruit bypassed bowel
   b. Bowel-lengthening procedure (Bianchi or STEP)
   c. Monitor for development of TPN-associated complications, and refer for transplant before recurrent sepsis, thrombosis, or end-stage liver disease

STEP, Serial transverse enteroplasty; *TPN,* total parenteral nutrition.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

PROGNOSIS

- Directly dependent on the extent of the bowel resection and in the case of Crohn disease by the underlying illness.
- Whether the colon remains in continuity with the small bowel is an important factor in the patient's ability to adapt after significant small bowel resection.

TABLE E4 Therapeutic Agents Used to Decrease Intestinal Transit and Diarrheal Volume in Patients with Short Bowel Syndrome (SBS)

Agent	Dosage
Loperamide*	4-6 mg 4× daily
Diphenoxylate-atropine*	2.5-5 mg 4× daily
Codeine phosphate*	15-60 mg 2-4× daily
Tincture of opium	0.6 ml (2.5 mg) 2-4× daily
Ranitidine†	300 mg twice daily
Omeprazole‡	40 mg twice daily
Octreotide	50-100 μg SC twice daily
Clonidine	0.3 mg transcutaneous patch once weekly

*The antidiarrheal agents loperamide, diphenoxylate-atropine, and codeine phosphate are given 1 hr before meals and at bedtime. Dosages may be increased over those recommended because of incomplete absorption in patients with SBS.
†Cimetidine, famotidine, and nizatidine are alternatives.
‡Esomeprazole, lansoprazole, rabeprazole, and pantoprazole are alternatives.
SC, subcutaneously.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

BASIC INFORMATION

DEFINITION

Short QT syndrome (SQTS) is a genetically inherited disorder of cardiac repolarization characterized by a severely shortened QT interval on the ECG, leading to atrial and ventricular arrhythmias and sudden cardiac death in affected individuals. This is a primary electrical disorder and patients have structurally normal hearts.

SYNONYM

SQTS

ICD-10CM CODE
I45.89 Other specified conduction disorders

EPIDEMIOLOGY AND DEMOGRAPHICS

- The disease is a relative new entity, first documented in 2000. In most (but not all) cases of SQTS, the QT or QTc (correct QT interval) has been <360 ms; however, there are many individuals with that QT interval who are clinically unaffected. Although poorly defined, the estimated prevalence of short QTc ≤340 ms is estimated to be 5 in 10,000 in persons less than 21 yr of age. Males are more commonly affected.
- Genetics: The disease is genetically heterogeneous and transmitted in an autosomal dominant fashion. Different genes encoding various cardiac ion channels have been attributed to SQTS, including a carnitine transporter and a chloride-bicarbonate anion exchanger. Based on this, eight SQTS have been described, from SQTS 1 to SQTS 8. SQT 1 is the most common variant described, due to a mutation in the cardiac ion channel KCNH2(HERG). SQTS 2 has been described to be sporadic, while the others are familial in nature.

PHYSICAL FINDINGS AND CLINICAL PRESENTATION

- Seen across all age groups, though most patients are children or young adults.
- Syncope and cardiac arrest are the most common presenting features. Syncope is likely due to ventricular arrhythmias. Sudden death can happen with exercise as well as at rest. Cardiac arrest is often the first manifestation of the disease with a peak incidence in the first yr of life and second peak between 20 and 40 yr of age; overall risk cardiac arrest is 40% before age 41.
- Atrial fibrillation and flutter are well described as being part of the syndrome.
- A significant percentage of patients are asymptomatic.

ETIOLOGY

- Cardiac repolarization abnormality
- A total of 22 different mutations have been found in 9 different genes, 15 in single families. At present, the chance of finding a causative mutation in a family with SQTS is approximately 20%. Mutations cause an increase in net outward current from either a reduction in inward depolarizing currents INa or ICa or augmentation of outward repolarizing currents I to I K1, I K-ATP, I ACh, I Kr or I Ks as well as defects in Cl/HCO_3 exchanger. The resultant shortening of the action potential causes a shortening of the effective refractory period, with subsequent increased susceptibility of both atrial and ventricular muscle to premature depolarizations that lead to AF and VF
- Acquired causes—see "Differential Diagnosis"

DIAGNOSIS

- The 2013 HRS guidelines define SQTS as follows:
  1. SQTS is diagnosed in the presence of a QTc ≤330 ms.
  2. SQTS can be diagnosed in the presence of a QTc ≤360 ms and one or more of the following: a pathogenic mutation, family history of SQTS, family history of sudden death at age ≤40, survival of a ventricular tachycardia/ventricular fibrillation episode in the absence of heart disease.
  3. Notably, more recent studies suggest the use of somewhat more liberal cutoffs of 340 ms as standalone and 370 ms in combination with additional risk factors.
- A proposed scoring system (Table 1) for the diagnosis of SQTS incorporates the above criteria but has not yet been fully endorsed by the current guidelines.
- The differential diagnosis of a short QT includes various conditions such as hyperkalemia, hypercalcemia, acidosis, digitalis toxicity, effect of acetylcholine or epinephrine, sinus tachycardia, or hyperthermia. All these are possible causes of an acquired short QT interval that must be ruled out before a diagnosis of SQTS can be entertained.

WORKUP

- Evaluation of any survivor of sudden death starts with a detailed history and physical examination, with particular emphasis on family history. Many patients with SQTS have unexplained syncope or palpitations prior to resuscitated sudden death. Atrial fibrillation is common in SQTS patients and a family history of lone AF should also be sought, in addition to resuscitated VF arrest.
- Physical examination is mostly normal in patients with SQTS.
- ECG findings in SQTS include not only an abnormally short QT interval (usually <360 msec), but usually also a short or even absent ST interval, with the T-wave appearing to emanate directly from the S-wave. T-waves are usually any combination of tall, narrow, and symmetric, with a prolonged Tpeak-Tend ratio (Fig. E1). Additionally, PQ-segment depression (PQD), defined as 0.05-mV PQ depression from the isoelectric TP segment, is more typically present in patients with SQTS. Another feature to look for is the lack of adaptation of the QT interval to the heart rate (diminished rate dependence) as a result of which the corrected QT interval can be misleading; therefore, QT measurement on resting ECG in SQTS is more accurate with heart rate as close to 60 as possible.

TABLE 1 SQTS Diagnostic Criteria

	Points
QTc, msec	
<370	1
<350	2
<330	3
Jpoint-Tpeak interval <120 msec	1
Clinical history	
History of sudden cardiac arrest	2
Documented polymorphic VT or VF	2
Unexplained syncope	1
Atrial fibrillation	1
Family history	
First- or second-degree relative with high-probability SQTS	2
First- or second-degree relative with autopsy-negative sudden cardiac death	1
Sudden infant death syndrome	1
Genotype	
Genotype positive	2
Mutation of undetermined significance in a culprit gene	1

SQTS, Short QTS syndrome; *VF,* ventricular fibrillation; *VT,* ventricular tachycardia.
A minimum of 1 point must be obtained in the electrocardiographic section in order to obtain additional points.
High-probability SQTS: ≥4 points; intermediate-probability SQTS: 3 points; low-probability SQTS: ≤2 points. Electrocardiogram: Must be recorded in the absence of modifiers known to shorten the QT. Jpoint-Tpeak interval must be measured in the precordial lead with the greatest amplitude T-wave. Clinical history: Events must occur in the absence of an identifiable etiology, including structural heart disease. Points can only be received for 1 of cardiac arrest, documented polymorphic VT, or unexplained syncope. Family history: Points can only be received once in this section.
Adapted from Gollob MH, Redpath CJ, Roberts JD: The short QT syndrome: proposed diagnostic criteria, *J Am Coll Cardiol* 57(7):802-812, 2011.

- Echocardiogram and cardiac MRI should be performed to confirm a lack of structural heart disease.
- Holter recordings and stress tests can document a lack of variation of the QT interval in relation to the RR cycle; this is an important aspect of establishing the diagnosis. The QT interval shortens only slightly with increasing heart rates, so the QT and QTc values approach normal levels during faster heart rates. The QT fails to lengthen at slower heart rates.
- At electrophysiology study, the atrial and ventricular refractory periods are usually very short (140 to 200 msec at a CL of 400 to 600 msec). Sustained atrial fibrillation or flutter with rapid ventricular rates is often induced with programmed stimulation in the atrium. The inducibility of VF in SQTS patients at EPS is about 60%. EPS has a role in adding to the diagnosis by demonstrating short A and V refractory periods (also seen in other channelopathies such as Brugada syndrome), but given its low sensitivity, it cannot be used for risk stratification.

LABORATORY TESTS

- Genetic testing is recommended for all patients in whom a diagnosis of SQTS is suspected. This is especially true if they have a clinical or family history of syncope or sudden death.
- Screening family members: Mutation-specific genetic testing is recommended for all first-degree relatives of a patient diagnosed with a genotype-positive short QT syndrome.

Rx TREATMENT

- There is no significant clinical data on how to approach patients with an isolated short QT interval ≤330 but no family or clinical history or genotype criterion (low and intermediate probability of SQTS). Risk stratification of these patients is not possible at this time; however, they should be referred to an electrophysiologist with expertise on this topic for comprehensive testing, including genetic testing.
- Asymptomatic patients with incidentally found SQTS should be followed without any prophylactic medication.
- Patients with QT <330 msec and one criterion from clinical/family history or genetic testing fall in the high probability category of SQTS and hence a higher-risk subgroup for sudden cardiac death. An ICD implant is recommended in this group for secondary and possibly also primary prevention against sudden cardiac death.
- ICD implantation is a class I indication in patients with the diagnosis of SQTS and who are survivors of cardiac arrest or have sustained ventricular arrhythmia if meaningful survival greater than 1 yr is expected.
- A peculiar issue in patients with SQTS implanted with an ICD is double counting of peaked T-waves that are closely coupled to the QRS complex. This often leads to inappropriate ICD shocks. Most ICDs have programming modifications that can be made to avoid this problem.
- Pharmacologic therapy is usually only advised in patients with multiple and frequent appropriate ICD shocks. Quinidine is the preferred agent in these cases.
- However, medications may be the mainstay of therapy in patients in whom an ICD cannot be implanted for various reasons, including in children in whom technical challenges are significant.
- Isoproterenol infusion is effective in the setting of refractory VF storm and SQTS.
- While many drugs, such as flecainide, sotalol, ibutilide, hydroquinone, and amiodarone, have been used in an attempt to increase the QT interval, most of the available data favor hydroquinidine as the drug of choice across all forms of the SQTS.
- On a special note, primary carnitine deficiency, which presents with SQTS and is associated with VF, is a rare autosomal recessive disorder caused by a defective transport of carnitine into the cell. Administration of oral DL-carnitine or L-carnitine 5g/day over time abolishes the changes on ECG.

REFERRAL

Consultation with an electrophysiologist is strongly recommended if SQTS is suspected.

PEARLS AND CONSIDERATIONS

- SQTS is a rare genetic syndrome causing arrhythmias and sudden death.
- Should be suspected in patients with QT interval <370 msec presenting with syncope, sudden cardiac death, or atrial fibrillation and a family history of the same.

BASIC INFORMATION

DEFINITION

Sialadenitis is an inflammation of one or multiple salivary glands. It may present as acute or chronic disease with multiple potential etiologies. This section focuses mainly on the workup and management of acute sialadenitis.

ICD-10CM CODE
K11.20 Sialadenitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Accounts for approximately 0.01% to 0.02% of hospital admissions.
- 30% to 40% of affected patients are postoperative patients.
- Parotid gland is most frequently affected, followed by the submandibular glands (Fig. E1).

PREDOMINANT SEX AND AGE:

- Affects men and women equally.
- Patients are usually in the sixth and seventh decades of life.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Pain and swelling of the affected salivary gland
- Increased pain with meals
- Erythema and localized tenderness at the duct opening
- Massage may express purulent discharge from duct orifice
- Induration and pitting of the skin, with involvement of the masseteric and submandibular spatial planes in severe cases

ETIOLOGY

- Ductal obstruction is generally from salivary stasis and increased salivary viscosity as a result of dehydration, medication-induced xerostomia, or poor dental hygiene. This predisposes patients to retrograde migration of bacteria, which can then lead to suppurative sialadenitis.
- Acute suppurative sialadenitis is a bacterial infection of the salivary gland. Most frequent infecting organisms are *Staphylococcus aureus* (50% to 90% of cases), streptococcal species, *Haemophilus influenzae,* and *E. coli;* more recently, anaerobic infections have been increasing in prevalence.
- Recent surgery, Sjögren syndrome, diabetes mellitus, hypothyroidism, renal failure, trauma, radiation therapy, chemotherapy, dehydration, and chronic illness are predisposing factors.
- Mumps is the most common cause of nonsuppurative acute sialadenitis. Majority of cases (>80%) occur in children younger than 15 yr.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Salivary gland neoplasm
- Ductal stricture
- Sialolithiasis
- Decreased salivary secretion as a result of medications (e.g., amitriptyline, diphenhydramine, anticholinergics)
- Dental infections
- Lymphoma
- Cervical adenitis
- Infected branchial cleft or sebaceous cysts

WORKUP

- Generally not necessary. Fig. E2 describes a diagnostic algorithm.
- Ultrasound or CT scan in patients not responding to medical treatment.

LABORATORY TESTS

- Generally not indicated
- Complete blood count with differential to possibly reveal leukocytosis with left shift
- Mumps antibodies if there is clinical suspicion
- Culture of purulent drainage from salivary duct opening or percutaneously should be obtained to provide useful information in tailoring antibiotic therapy if the patient is not responding to empiric therapy

IMAGING STUDIES

- Ultrasound or CT scan may be needed in patients with no improvement or clinical worsening after 48 to 72 hours of medical therapy. This can provide information on the presence of a drainable collection.
- Sialography should not be performed during the acute phase, as it can worsen symptoms.
- MRI is also of little utility in acute sialadenitis.

TREATMENT

Nonpharmacologic therapy—these interventions are crucial in expediting resolution of symptoms.

- Massage of the gland: May express pus and relieve some of the pressure
- Hydration with intravenous fluid or aggressive oral hydration along with electrolyte repletion
- Warm compresses
- Oral cavity irrigations
- Administration of sialagogues such as lemon drops or vitamin C lozenges

ACUTE GENERAL Rx

- Amoxicillin-clavulanate 500 to 875 mg bid or cefuroxime 250 to 500 mg bid should be given for 10 days. Clindamycin is an alternative choice in patients allergic to penicillin.
- In patients coming from nursing homes or in cases of nosocomial infections, consider empiric treatment with vancomycin given the prevalence of methicillin-resistant *S. aureus.*
- IV antibiotics (e.g., cefoxitin, nafcillin) can be given in severe cases.
- Patients generally improve with 48 to 72 hours of medical treatment. If there is no improvement, consider imaging with CT or ultrasound.
- Surgical drainage is indicated for the rare cases that are refractory to medical management and that are found to have an abscess on CT or ultrasound.

DISPOSITION

Complete recovery unless the patient has underlying obstruction (e.g., ductal stricture, tumor, or stone)

REFERRAL

- To ear-nose-throat specialist for cases refractory to appropriate medical therapy
- For salivary gland incision and drainage, which may be necessary in resistant cases

PEARLS & CONSIDERATIONS

COMMENTS

Prevention of dehydration will decrease the risk of sialadenitis.

Sialolithiasis ALG PTG

BASIC INFORMATION

DEFINITION

Sialolithiasis is the existence of hardened intraluminal deposits in the ductal system of a salivary gland.

SYNONYMS

Salivary gland stone
Salivary calculus

ICD-10CM CODE
K11.5 Sialolithiasis

EPIDEMIOLOGY & DEMOGRAPHICS

Affects patients mostly in the fifth to eighth decades and occurs most commonly in the submandibular gland (85%); 15% of occurrences are located in a parotid gland (Table E1).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms: Colicky postprandial pain and swelling of a salivary gland. Tends to have a remitting/relapsing course.
- Signs: Swelling and tenderness of a salivary gland. The stone may be felt with bimanual palpation of the floor of the mouth or inner cheek.

ETIOLOGY

- The cause is unknown. Contributing factors include saliva stagnation, sialadenitis (inflammation of a salivary gland), ductal inflammation, or injury (Fig. 1).
- Gout is a known cause of salivary gland calculi.
- Salivary calculus composition is mainly calcium phosphate and carbonate, often combined with small proportions of magnesium, zinc, ammonium salts, and organic materials or debris.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphadenitis
- Salivary gland tumor
- Salivary gland bacterial (*Staphylococcus* or *Streptococcus*), viral (mumps), or fungal infection (sialadenitis)
- Noninfectious salivary gland inflammation (e.g., Sjögren syndrome, sarcoidosis, lymphoma)
- Salivary duct stricture
- Dental abscess

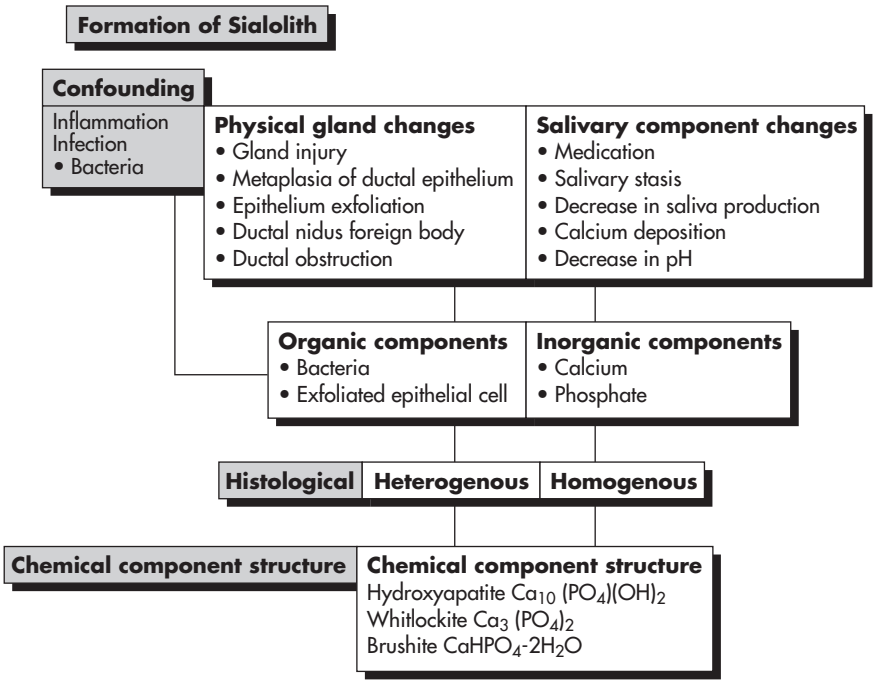

FIG. 1 Algorithm of clinical findings and pathogenesis of sialolithiasis. (From Lee LT, Wong YK: Sialolithiasis in minor salivary glands, *J Oral Maxillofac Surg*, 2010.)

IMAGING STUDIES

- X-ray: 90% of submandibular stones are radiopaque and will show up on x-ray. 90% of parotid stones are radiolucent and will not show up on x-ray.
- Non–contrast-enhanced computed tomography is very useful in detecting nearly all salivary stones.
- Ultrasound can detect 90% of salivary stones >2 mm.
- Sialography has a 95% to 100% sensitivity in detecting stones (Figs. E2 and E3), although it is more invasive than the above options and requires contrast injection into the affected duct.

TREATMENT

- Nonsurgical management is usually the first-line treatment.
  1. Warm compresses, gland massages, sialogogues (lemon wedges, sour candies), IV or oral hydration.
  2. Antibiotics if associated bacterial sialadenitis is present.
- Surgical treatment:
  1. The surgical approach depends on the location of the stone. Submandibular stones in the distal aspect of the duct that are palpable may be excised transorally under local anesthesia. More proximal stones may require removal of the submandibular gland. Sialoendoscopy is a newer technique where a rigid endoscope and specialized instruments and/or lasers are used to visualize and remove the stones. Stones in the parotid duct also may be accessible via the transoral approach or may require parotidectomy. Sialoendoscopy is also an option for parotid stones.
  2. Extracorporeal shock wave lithotripsy is an alternative technique that breaks up the stones into smaller fragments that can be secreted naturally through the duct.

REFERRAL

To otorhinolaryngologist

BASIC INFORMATION

DEFINITION

Sinus node dysfunction is a group of cardiac rhythm disturbances characterized by abnormalities of the sinus node leading to the inability of the SA node to react to heart rate changes to meet physiological demands. This entity includes (1) chronic, inappropriate bradycardia; (2) sinus pauses or arrest; (3) sinoatrial exit block; and (4) alternating sinus bradycardia with paroxysmal supraventricular tachyarrhythmias (frequently atrial fibrillation) known as tachycardia-bradycardia syndrome. When sinus node dysfunction is associated with symptoms, it is called sick sinus syndrome (SSS).

SYNONYMS

Sinus pause
Sinus arrest
Inappropriate persistent sinus bradycardia
Tachycardia-bradycardia syndrome
Sinoatrial exit block
SSS
Bradycardia-tachycardia syndrome

ICD-10CM CODE
I49.5 Sick sinus syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- In children: Associated with congenital and acquired heart disease, particularly after cardiac surgery.
- In adults: It is primarily a disease of the elderly secondary to progressive idiopathic degenerative disease. A modern population study has suggested that white race, increased BMI, prolonged baseline QRS or right bundle branch block, elevated N-terminal pro-B-type natriuretic peptide, HTN, or other cardiovascular diseases are associated with increased incidence of sick sinus syndrome. With an aging population, the annual incidence of SSS is projected to increase significantly.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fatigue, light-headedness, syncope, presyncope, palpitations. Other manifestations include dyspnea on exertion and worsening angina.
  1. Usually symptoms are progressive; however, abrupt symptoms are not uncommon (i.e., syncope).
- Physical examination may be normal or reveal abnormalities (e.g., irregular heart rhythm, signs of congestive heart failure, heart murmurs or gallop sounds) associated with the underlying heart disease.

ETIOLOGY

- Sinus node fibrosis is the primary etiology, which may also affect the atrioventricular node, the His bundle, or its branches. Polypharmacy should be considered and obtaining an accurate medicine list is essential.
  1. Common medications include beta blockers, nondihydropyridine calcium channel blockers, digoxin, and antiarrhythmic medications.
- Additional etiologies include acute coronary syndromes, diseases of the SA nodal artery, inflammatory and infiltrative diseases such as hemochromatosis, amyloidosis, sarcoidosis, collagen vascular diseases (SLE and scleroderma), epicardial and pericardial diseases, trauma following cardiac surgery, hypothyroidism, hypothermia, hypoxia, sepsis, muscular dystrophies (e.g., myotonic dystrophy, Friedreich ataxia), infectious etiologies such as Lyme disease, increased intracranial pressure.
  1. The sinus node artery arises from right coronary artery in 55% to 60% of people and the left circumflex artery in 40%.

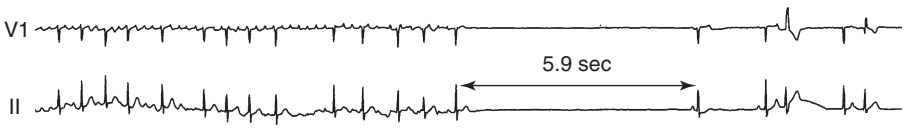

FIG. 1 Tachycardia-bradycardia syndrome. Two surface electrocardiogram leads show atrial fibrillation that spontaneously terminates followed by a 5.9-second pause before sinus rhythm resumes. The patient became light-headed during this period. (From Issa Z et al: *Clinical arrhythmology and electrophysiology,* ed 2, Philadelphia, 2012, Saunders.)

TABLE 1 Indications for Permanent Pacing in Sinus Node Dysfunction

Class	Indications
I	• Sinus node dysfunction with documented symptomatic bradycardia or sinus pauses that produce symptoms • Symptomatic sinus bradycardia that is iatrogenic and will occur as a consequence of essential long-term therapy of a type and dose of drugs for which there are no acceptable alternatives • Symptomatic chronotropic incompetence
IIa	• Sinus node dysfunction, occurring spontaneously or as a result of necessary drug therapy, with a heart rate of less than 40 beats/min when a clear association between significant symptoms consistent with bradycardia has not been documented • Unexplained syncope when sinus abnormalities are observed or provoked with electrophysiologic study
IIb	• A chronic heart rate of less than 40 beats/min, while awake, in the minimally symptomatic patient
III	• Sinus node dysfunction in asymptomatic patients, including those in whom substantial sinus bradycardia (heart rate of less than 40 beats/min) is a consequence of long-term drug treatment • Sinus node dysfunction in which symptoms suggestive of bradycardia are clearly documented as not associated with a slow heart rate • Symptomatic bradycardia associated with nonessential drug therapy

ACC, American College of Cardiology; *AHA,* American Heart Association; *HRS,* Heart Rhythm Society.
Adapted from ACC/AHA/HRS 2008 revised guidelines with 2012 update.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bradycardia: Atrioventricular block
- Tachycardia: Atrial fibrillation or atrial flutter, sinus tachycardia
- Medication toxicity
- Carotid sinus hypersensitivity
- Metabolic abnormality (e.g., hyperkalemia in acute kidney injury)

WORKUP

- ECG (Fig. 1)
- Ambulatory cardiac rhythm monitoring
- Twenty-four-hour ambulatory ECG (Holter) with diary to correlate symptoms to findings:
  1. Event recorder or an implantable loop recorder if symptoms are less frequent.
  2. Establishment of diagnosis is more effective with longer-term recording (at least 2-4 wk) compared with 24-hour ambulatory ECG.
  3. Exercise stress testing to evaluate the severity of chronotropic incompetence.
  4. The term *chronotropic incompetence* is felt to represent the inability to augment heart rates appropriately in response to exercise or activities of daily living.
- Electrophysiologic testing, including sinus node recovery time and sinoatrial conduction time

TREATMENT

- Permanent pacemaker placement is primarily indicated if bradycardia is symptomatic and a reversible etiology is not identified. Indications for permanent pacemaker in sinus node dysfunction are described in Table 1.
- In tachycardia-bradycardia syndrome, drug treatment is indicated for tachycardia, primarily with AV node blocking agents, after placement of the permanent pacemaker.

BASIC INFORMATION

DEFINITION

- Sickle cell disease (SCD) is a hemoglobin disorder in which the substitution of valine for glutamic acid at position six of the beta globin chain yields a variant hemoglobin, hemoglobin S. When hemoglobin S is not bound to oxygen (deoxy HgbS) it can polymerize into long strands, deforming red blood cells (RBCs) into a characteristic sickle shape. Chronic RBC membrane damage from this process locks cells into the sickle shape. These abnormal cells can obstruct the microcirculation because of abnormal adherence to vascular endothelium, causing painful crises, which are the hallmark of sickle cell disease.
- Patients with SCD include those who are homozygous for sickle cell hemoglobin (HbSS), also called sickle cell anemia (SCA), and those with one sickle hemoglobin gene inherited with other hemoglobin abnormalities, notably beta thalassemia (Hgb S/β^0 or Hgb S/β^+ thalassemia) and hemoglobin C (HbSC).

SYNONYMS

Sickle cell anemia
SCA
SCD
Hemoglobin S disease

ICD-10CM CODES

D57.1	Sickle-cell disease without crisis
D57.20	Sickle-cell/Hb-C disease without crisis
D57.211	Sickle-cell/Hb-C disease with acute chest syndrome
D57.212	Sickle-cell/Hb-C disease with splenic sequestration
D57.219	Sickle-cell/Hb-C disease with crisis, unspecified
D57.3	Sickle-cell trait
D57.40	Sickle-cell thalassemia without crisis
D57.411	Sickle-cell thalassemia with acute chest syndrome
D57.412	Sickle-cell thalassemia with splenic sequestration
D57.419	Sickle-cell thalassemia with crisis, unspecified
D57.80	Other sickle-cell disorders without crisis
D57.811	Other sickle-cell disorders with acute chest syndrome
D57.812	Other sickle-cell disorders with splenic sequestration
D57.819	Other sickle-cell disorders with crisis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Sickle cell disease is an autosomal-recessive disorder. In African Americans, the incidence of sickle cell anemia at birth is 1 in 600 and the incidence of all genotypes of sickle cell disease is 1 in 300. Approximately 90,000 people in the U.S. have sickle cell disease.
- Sickle cell trait occurs in approximately 300 million people worldwide, with the highest prevalence of approximately 30% to 40% in sub-Saharan Africa, but also in the southern Mediterranean region (usually as Hgb S/β^0 or Hgb S/β^+), parts of the Middle East, and India. In the U.S., it is found in nearly 10% of African Americans.
- An estimated 2000 babies are born with sickle cell disease in the U.S. each yr, and worldwide 275,000 infants are born with the disease annually.
- There is no predominant sex.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination is variable depending on the degree of anemia and presence of acute vasoocclusive syndromes, as well as acute pulmonary, neurologic, cardiovascular, genitourinary, and musculoskeletal complications. Table 1 summarizes organ damage seen in sickle cell disease.
- A study of the prevalence of pain in sickle cell patients found that patients complained of pain on 55% of days surveyed; another study showed 40% to 80%. Chronic pain may be due to avascular necrosis of joints and is sometimes poorly explained.
- There is no clinical laboratory finding that is pathognomonic of painful crisis of sickle cell disease. The diagnosis of a painful episode is made solely on the basis of the medical history and physical examination. Elevated total bilirubin and lactate dehydrogenase (LDH) are sometimes seen with crisis due to increased hemolysis. However, hemolytic anemia is typical for sickle cell disease at baseline. "Aplastic crisis" refers to crisis presenting with severe anemia and low reticulocyte count, usually caused by B19 parvovirus infection.
- Bones are the most common site of pain. Dactylitis, or hand-foot syndrome (acute, painful swelling of the hands and feet), is the first manifestation of sickle cell disease in many infants. Irritability and refusal to walk are other common symptoms. After infancy, musculoskeletal pain can be symmetric, asymmetric, or migratory, and it may or may not be associated with swelling, low-grade fever, redness, or warmth.
- In both children and adults, sickle vasoocclusive episodes are difficult to distinguish from osteomyelitis, septic arthritis, synovitis, rheumatic fever, or gout.
- Cholecystitis should be considered when abdominal pain is present because this is common in patients with chronic hemolysis. In general, localizing symptoms for infection (e.g., urinary symptoms) should be evaluated because these can trigger sickle crisis. Whereas patients with severe sickle cell disease have splenic atrophy in adulthood, patients with milder disease (e.g., Hgb S/C) may have splenic infarct pain in adulthood.
- The acute chest syndrome is a potentially life-threatening complication of sickle cell disease that manifests with chest pain, fever, wheezing, tachypnea, and cough. Chest radiograph may reveal pulmonary infiltrates. Causes include infection (*Mycoplasma, Chlamydia,* viruses), infarction, and fat embolism, but often no cause is identified.
- Musculoskeletal and skin abnormalities seen in sickle cell anemia include leg ulcers (particularly on the malleoli) and limb-girdle deformities caused by avascular necrosis of the femoral and humeral heads. Osteonecrosis of the heads of the femur and humerus is found in nearly 50% of adults with Hgb S/S sickle cell disease.
- Endocrine abnormalities include delayed sexual maturation and late physical maturation, especially evident in boys.
- Neurologic abnormalities on examination may include seizures and altered mental status. Strokes occur in about 10% of children and adults with sickle cell anemia and approximately 35% of children with sickle cell anemia have cerebrovascular disease.
- Infections, particularly involving *Salmonella, Staphylococcus aureus, Mycoplasma,* and *Streptococcus,* are relatively common. Catheter-associated bacteremia should be considered if a vascular access device is present; these may present without fever.
- Severe splenomegaly as a result of sequestration often occurs in children before splenic atrophy.

TABLE 1 Organ Damage Seen in Sickle Cell Disease

Organ or System	Injury
Skin	Stasis ulcer
Central nervous system	Cerebrovascular accident
Eye	Retinal hemorrhage, retinopathy
Cardiac	Congestive heart failure
Pulmonary	Intrapulmonary shunting, embolism, infarct, infection
Vascular	Occlusive phenomenon at any site
Liver	Hepatic infarct, hepatitis resulting from transfusion, hepatic sequestration, intrahepatic cholestasis
Gallbladder	Increased incidence of bilirubin gallstones caused by hemolysis
Spleen	Acute sequestration
Urinary	Hyposthenuria, hematuria
Genital	Decreased fertility, impotence, priapism
Skeletal	Bone infarcts, osteomyelitis, aseptic necrosis
Placenta	Insufficiency with fetal wastage
Leukocytes	Relative immunodeficiency
Erythrocytes	Chronic hemolysis

From Marx J et al: *Rosen's emergency medicine: concepts and clinical practice,* ed 7, Philadelphia, 2010, Mosby.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Thalassemia
- Other hemolytic anemias
- The differential diagnosis of patients presenting with a painful crisis is discussed in "Physical Findings"

TABLE 2 Baseline Evaluations to Consider

	Tests
Blood tests	CBC with differential
	Reticulocyte count
	Hemoglobin HPLC or electrophoresis
	LDH
	Renal function tests
	Liver function tests
	Mineral panel
	Serum iron, ferritin, TIBC
	Vitamin D level
	Hepatitis B sAg
	Hepatitis C antibody
	RBC alloantibody screen
	RBC typing
	D-dimer[a]
	C-reactive protein[a]
	Brain natriuretic peptide
Urine and kidney tests	Urinalysis
	Renal ultrasonography[b]
Radiology	MRI or MRA brain (adults)[c] or transcranial Doppler ultrasonography starting at age 2 yr (children)
	Chest radiography[d]
	Hip or shoulder radiograph or MRI (or both)[c]
	Bone density in teenagers and adults
Cardiology and pulmonary	Echocardiogram
Neurocognitive	Neurocognitive testing[d]

CBC, Complete blood count; *HPLC,* high performance liquid chromatography; *LDH,* lactate dehydrogenase; *MRA,* magnetic resonance angiography; *MRI,* magnetic resonance imaging; *RBC,* red blood cell; *sAg,* surface antigen; *TIBC,* total iron-binding capacity.
[a]Consider following as surrogate markers after initiation of disease-modifying intervention.
[b]If hematuria with red blood cells in urine.
[c]As clinically indicated.
[d]If the patient has poor school performance, an abnormal memory, or abnormal MRI findings.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

WORKUP (TABLE 2)

- Screening of all newborns regardless of racial background is performed in the U.S. Screening can be performed with sodium metabisulfite reduction test (Sickledex test).
- Hemoglobin electrophoresis will also confirm the diagnosis and is useful to identify hemoglobin variants such as fetal hemoglobin and hemoglobin C.
- Patients will have evidence of hemolysis (elevated reticulocyte count, low haptoglobin, variable elevation of LDH and total bilirubin).
- Chest x-ray often reveals typical vertebral body changes ("fish mouth" vertebrae) caused by chronic vasoocclusive injury to vertebral bodies.
- For prenatal diagnosis, initial step is identification of parenteral globin gene mutation by DNA-based testing. If positive, then DNA-based testing of chorionic villus sampling or amniotic fluid cells is performed.

LABORATORY TESTS

- Anemia (resulting from chronic hemolysis), reticulocytosis, leukocytosis, and thrombocytosis are common. Hgb S/β^0 and Hgb S/β^+ thalassemia will have microcytosis; Hgb S/C is also typically microcytic. Hgb S/C may have normal or near-normal hematocrit, but will have characteristic changes on peripheral smear (target cells).
- Elevations of bilirubin and lactate dehydrogenase are also common, as is low haptoglobin, consistent with chronic hemolysis.
- Peripheral blood smear may reveal sickle cells, target cells, poikilocytosis, and hypochromia (Fig. 1).
- Elevated blood urea nitrogen and creatinine may be present in patients presenting acutely with dehydration or chronically with progressive renal insufficiency.
- Urinalysis may reveal hematuria and proteinuria. Patients with SCD should be screened for microalbuminuria and proteinuria with spot urine testing by 10 yr of age.

IMAGING STUDIES (FIGS. E2 AND E3)

- Chest x-ray or noncontrast chest CT scan to evaluate acute and chronic lung changes is helpful.
- Routine skeletal imaging is rarely helpful in acute crisis and should usually be reserved for pain that is not consistent with transient acute crisis.
- MRI or bone scan is useful to address chronic avascular necrosis or, in the acute setting, osteomyelitis.
- CT scan or MRI of brain is not indicated in asymptomatic adults and children with SCD but is often needed in patients with neurologic complications such as transient ischemic attack, cerebrovascular accident, seizures, or altered mental status.
- Transcranial Doppler ultrasonography (TCD) is used to identify children with sickle cell anemia who are at risk for stroke. There should be an annual screening starting at age 2 until age 16. Patients determined to be at risk (transcranial Doppler velocity ≥200 cm/s) should be enrolled in long-term transfusion programs. These are effective in reducing risk of stroke by >90%. In adults, magnetic resonance angiography (MRA) can be used instead of TCD to identify those at risk for stroke.
- Doppler echocardiography should be performed in patients with unexplained respiratory symptoms to evaluate for pulmonary hypertension, with right heart catheterization performed if abnormal. Screening for vasculopathy is done by estimating the tricuspid regurgitant jet velocity (TRV). Elevated values are predictive of early mortality. The prevalence of pulmonary hypertension when right heart catheterization is performed is approximately 6% in adults with sickle cell disease.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Patients should be instructed to avoid conditions that may precipitate sickling crisis, such as extremes of cold and heat and dehydration.
- Maintain adequate hydration (PO or IV).
- Correct hypoxia when present.

ACUTE GENERAL Rx

- Initiate aggressive IV or oral hydration; most patients in crisis have evidence of dehydration.
- Aggressively diagnose and treat suspected infections such as urinary infection, respiratory infections, or catheter-associated line infections. Table 3 summarizes bacteria and viruses that most frequently cause serious infection in patients with sickle cell disease.
- Provide pain relief during the vasoocclusive crisis (Table 4). Most patients will have a treatment history that can guide dosing. Opiate management is complicated by high levels of tolerance in patients often treated over many yrs. Patient-controlled analgesic pumps are often helpful; caution should be used when employing continuous infusions, which are usually not necessary or helpful. Morphine and hydromorphone are most commonly used. Meperidine is rarely used now and generally discouraged because of neurologic side effects, although some patients state a preference for it.
- Oral diphenhydramine (Benadryl) is used to control pruritus, which is commonly associated with opiate analgesics; preferred to IV therapy in guidelines.

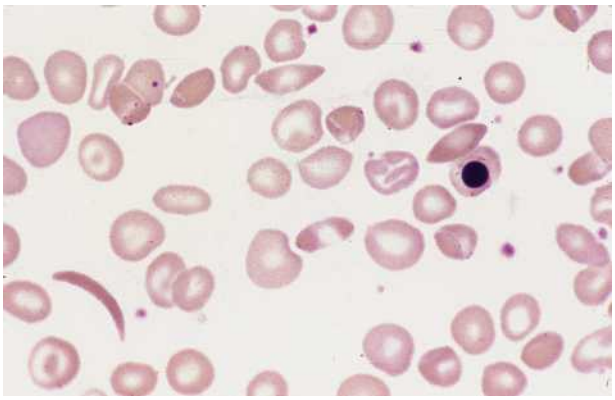

FIG. 1 Photomicrograph of a blood film. Sickle cell anemia (homozygosity for hemoglobin S). Shown are a sickle cell, boat-shaped cells, a nucleated red cell, and target cells. (From Bain BJ et al: *Dacie and Lewis practical haematology,* ed 12, Philadelphia, 2017, Elsevier.)

TABLE 3 Bacteria and Viruses That Most Frequently Cause Serious Infection in Patients with Sickle Cell Disease

Microorganism	Type of Infection	Comments
Streptococcus pneumoniae	Septicemia	Common despite prophylactic penicillin and pneumococcal vaccine
	Meningitis	Less frequent than in yrs past
	Pneumonia	Rarely documented except in infants and young children
	Septic arthritis	Uncommon
Haemophilus influenzae type b	Septicemia	
Meningitis		
Pneumonia	Much less common in recent yrs because of immunization with conjugate vaccine	
Salmonella species	Osteomyelitis	
Septicemia	Most common cause of bone and joint infection	
Escherichia coli and other gram-negative enteric pathogens	Septicemia	
Urinary tract infection		
Osteomyelitis	Focus sometimes not apparent	
Staphylococcus aureus	Osteomyelitis	Uncommon
Mycoplasma pneumoniae	Pneumonia	Pleural effusions; multilobe involvement
Chlamydia pneumoniae	Pneumonia	
Parvovirus B19	Bone marrow suppression (aplastic crisis)	High fever common; rash and other organ involvement infrequent
Hepatitis viruses (A, B, and C)	Hepatitis	Marked hyperbilirubinemia

Data from Buchanan GR, Glader BE: Benign course of extreme hyperbilirubinemia in sickle cell anemia: analysis of six cases, *J Pediatr* 91:21, 1977. From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

- Table 5 summarizes overall strategies for the management of acute chest syndrome.
- Follow oxygenation in patients presenting with chest pain or respiratory symptoms; assess for evolving acute chest syndrome if oxygenation deteriorates.
- Urology evaluation for priapism.

CHRONIC Rx

- Hydroxyurea increases hemoglobin F levels and reduces the incidence of vasoocclusive complications. It is helpful in patients with Hgb S/S and S/β^0 thalassemia; its value in other variants is less certain. A study of hydroxyurea with 17.5 yr of follow-up showed evidence of improved survival and no safety signals. There is strong evidence to support use of hydroxyurea therapy in children 9 mo and older to decrease the frequency of vasoocclusive crises and acute chest syndrome. Hydroxyurea therapy is also strongly recommended for adults with three or more vasoocclusive crises during any 12-mo period, with SCD pain or chronic anemia interfering with daily activities, or with severe or recurrent episodes of acute chest syndrome. Recommended starting doses are 15 mg/kg/day in adults, 5 to 10 mg/kg/day in patients with renal disease, and 20 mg/kg/day in children. It should be stopped in pregnancy and contraception counseling should be given to patients taking it.
- Pharmaceutical grade L-glutamine is approved to decrease crisis symptoms in patients with Hgb S/S and Hgb S/β^0 thalassemia; benefits include decrease in acute crisis episodes, reduced hospitalization, and decrease in episodes of acute chest syndrome. Dosing is 5 to 15 g twice daily, taken with food or 8 oz of cold or room-temperature fluid. Constipation, nausea, headache, and abdominal discomfort were common side effects, occurring in about 15% to 20% of patients. It may work with or without concomitant use of hydroxyurea. Caution may be warranted in prescribing L-glutamine to patients with clinically significant renal or hepatic dysfunction.
- Replace folic acid (1 mg PO qd) due to loss from increased utilization of folic acid stores from to chronic hemolysis. Sickle cell patients also often have mineral and vitamin deficiencies (calcium, zinc, and vitamins A, C, D, and E) and may need vitamin and nutritional supplementation.
- Chronic pain management represents an enduring challenge, made more difficult by the current opiate addiction and overdose epidemic. In one study, patients reported pain 55% of days. Review of guidelines for safe opiate prescribing is strongly recommended and management with pain management specialists is also strongly recommended.
- Indications for transfusion in sickle cell disease are described in Table 6. Urgent exchange transfusion for acute chest syndrome with progressive hypoxia (arterial oxygen saturation <90%) or multiorgan failure may be lifesaving. Simple transfusion may be adequate in milder cases with a target Hgb of 10 g/dl. Transfusion therapy is appropriate for patients with stroke or at high risk by transcranial Doppler study (see earlier) if possible. Transfusion has shown benefit in children with silent infarcts by MRI in preventing progression. Transfusion to Hgb 10 g/dl is recommended in anemic patients undergoing general anesthesia to reduce crisis and respiratory complications after surgery. Patients on chronic transfusion therapy should receive RBC matched at C, E, and K antigens to avoid alloimmunization. Transfusion is not recommended for asymptomatic anemia. Serum ferritin level should be monitored quarterly. Iron overload due to blood transfusions (transfusional hemosiderosis) can be treated with chelating agents (deferoxamine [SC infusion], deferasirox [PO], and deferiprone [PO]).
- Annual screening for proteinuria is recommended. Angiotensin-converting enzyme inhibitor therapy should be started for microalbuminuria in adults with SCD to prevent progression of renal injury. Progressive renal injury may cause worsening anemia and responds to erythropoietin.

TABLE 4 Recommended Dose and Interval of Analgesics Necessary to Obtain Adequate Pain Control in Patients with Sickle Cell Disease

	Dose/Rate	Comments
Severe to Moderate Pain		
Morphine	Parenteral: 0.1-0.15 mg/kg every 3-4 h Recommended maximum single dose, 10 mg PO: 0.3-0.6 mg/kg every 4 h	Drug of choice for pain; lower doses in elderly adults and infants and in patients with liver failure or impaired ventilation
Meperidine	Parenteral: 0.75-1.5 mg/kg every 2-4 h Recommended maximum dose, 100 mg PO: 1.5 mg/kg every 4 h	Increased incidence of seizures; avoid in patients with renal or neurologic disease and those who receive MAOIs
Hydromorphone	Parenteral: 0.01-0.02 mg/kg every 3-4 h PO: 0.04-0.06 mg/kg every 4 h	
Oxycodone	PO: 0.15 mg/kg/dose every 4 h	
Ketorolac	IM: Adults: 30 or 60 mg initial dose followed by 15-30 mg; children: 1 mg/kg load followed by 0.5 mg/kg every 6 h	Equal efficacy to 6 mg MS; helps narcotic-sparing effect; not to exceed 5 days; maximum, 150 mg first day, 120 mg maximum on subsequent days; may cause gastric irritation
Butorphanol	Parenteral: Adults: 2 mg every 3-4 h	Agonist–antagonist; can precipitate withdrawal if given to patients who are being treated with agonists
Mild Pain		
Codeine	PO: 0.5-1 mg/kg every 4 h Maximum dose, 60 mg	Mild to moderate pain not relieved by aspirin or acetaminophen; can cause nausea and vomiting
Aspirin	PO: Adults: 0.3-6 mg every 4-6 h; children: 10 mg/kg every 4 h	Often given with a narcotic to enhance analgesia; can cause gastric irritation; avoid in febrile children
Acetaminophen	PO: Adults: 0.3-0.6 g every 4 h; children: 10 mg/kg	Often given with a narcotic to enhance analgesia
Ibuprofen	PO: Adults: 300-400 mg every 4 h; children: 5-10 mg/kg every 6-8 h	Can cause gastric irritation
Naproxen	PO: Adults: 500 mg/dose initially and then 250 every 8-12 h; children: 10 mg/kg/day (5 mg/kg every 12 h)	Long duration of action; can cause gastric irritation
Indomethacin	PO: Adults: 25 mg every 8 h; children: 1-3 mg/kg/day given 3 or 4 times	Contraindicated in psychiatric, neurologic, renal diseases; high incidence of gastric irritation; useful in gout

IM, Intramuscular; *MAOI,* monoamine oxidase inhibitor; *MS,* morphine sulphate; *PO,* oral.

Adapted from Charache S et al: Effect of hydroxyurea on the frequency of painful crises in sickle cell anemia: Investigators of the Multicenter Study of Hydroxyurea in Sickle Cell Anemia, *N Engl J Med* 332:1317, 1995. In Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 5 Overall Strategies for the Management of Acute Chest Syndrome

Prevention

Incentive spirometry and periodic ambulation in patients admitted for sickle cell pain, surgery, or febrile episodes
Watchful waiting in any hospitalized child or adult with sickle cell disease (pulse oximetry monitoring and frequent respiratory assessments)
Cautious use of intravenous fluids
Intense education and optimum care of patients who have sickle cell anemia and asthma

Diagnostic Testing and Laboratory Monitoring

Blood cultures, if febrile
Nasopharyngeal samples for viral culture (respiratory syncytial virus, influenza), depending on clinical setting
Complete blood counts every day and appropriate chemistries
Continuous pulse oximetry
Chest radiographs for persistent or progressive illness

Treatment

Blood transfusion (simple or exchange) depending on clinical features; consider maintaining an active type and crossmatch
Supplemental O_2 for drop in pulse oximetry by 4% over baseline, or values <90%
Empirical antibiotics (third-generation cephalosporin and macrolide)
Continued respiratory therapy (incentive spirometry and chest physiotherapy as necessary)
Bronchodilators and corticosteroids for patients with asthma
Optimum pain control and fluid management

From Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

- Annual retinopathy screening should be performed beginning at age 10, especially for patients with Hgb S/C variant, in whom proliferative retinopathy occurs in about 30% to 50%. It is less common in Hgb S/S and other variants.
- Gene therapy for patients with sickle cell disease represents a novel approach. Clinical trials with lentiviral vector-mediated addition of an antisickling β-globin gene into autologous hematopoietic stem cells are ongoing with encouraging early results in terms of reduction of sickle cell crises and correction of the biologic hallmarks of the disease.
- Allogeneic stem cell transplantation can be curative in young patients with symptomatic sickle cell disease.
- A recent phase 2 trial for the prevention of pain crises in sickle cell disease involving crizanlizumab, an antibody against the adhesion molecule p-selectin, revealed a significantly lower rate of sickle cell–related pain crisis than placebo and was associated with a low incidence of adverse events.
- A recent phase 3 trial with Voxelotor, an inhibitor of sickle hemoglobin (HbS) polymerization revealed that Voxelotor significantly increased hemoglobin levels and reduced markers of hemolysis.[1]
- Penicillin V 125 mg PO bid should be administered by age 2 mo and increased to 250 mg bid by age 3 yr. Penicillin prophylaxis can be discontinued after age 5 yr except in children who have had splenectomy.
- Table 7 summarizes disease-modifying treatments to consider.

REFERRAL

- Hospitalization for pain crisis unresponsive to oral analgesics, or involving fever, respiratory symptoms, or vomiting and diarrhea.
- Optimal management requires coordination with hematology, blood banking, pain management, and psychosocial counseling and support. ferral for patients with organ-specific complications, notably pulmonary hypertension,

[1]Vichinsky E et al: A phase 3 randomized trial of Voxelotor in sickle cell disease, *N Engl J Med* 381:509-519, 2019.

TABLE 6 Indications for Transfusion in Sickle Cell Disease

	Duration	Consensus	Method	Goal*
Stroke, acute	Single	+	Ex	HbS <30%
Stroke, ongoing care	Chronic	+	Either	HbS <30%
High-velocity transcranial Doppler	Chronic	+	Either	HbS <30%
ACS, initial episode	Single	+	Dir > Ex	Hgb 10
ACS, recurrent	6-12 mo	+	Either	
Pulmonary hypertension	Chronic	+	Either	
Multiorgan failure	Single	+	Ex	
Major surgery	Single	+	Dir	Hgb 10
Acute anemia	Single	+	Dir	
Recurrent spleen sequestration	Chronic	+		
Sepsis/meningitis	Single	+	Dir	
Severe chronic pain	6-12 mo	+		
Congestive heart failure	Chronic	+		
Silent infarct with abnormal neuropsychology	Chronic	–		
Pregnancy		–		
Anemia/renal failure	Chronic	–		
Leg ulcers	6-12 mo	–		
Severe growth delay		–		
Severe eye disease		–		
Priapism		–		

ACS, Acute chest syndrome; *Dir,* direct; *Ex,* exchange; *Hb,* hemoglobin type; *Hgb,* hemoglobin concentration; +, consensus reached; –, consensus not reached.
*Goal of transfusion if a consensus has been reached.
From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, Saunders.

TABLE 7 Disease-Modifying Treatments to Consider[a]

Robust clinical data	Penicillin prophylaxis
	Streptococcus pneumoniae vaccination
	Hydroxyurea
	Chronic exchange transfusion
	Iron chelation for chronic iron overload[b]
Limited clinical data	Daily multivitamin without iron or folate supplementation *and* vitamin D replacement[c]
	Haemophilus influenzae vaccination
	Influenza vaccination
	Erythropoietin
	Phlebotomy
Experimental	Hb F reactivation with decitabine, histone deacetylase inhibitors, or imids
	Erythropoietin for chronic relative reticulocytopenia
	Nutritional supplements and antioxidants (e.g., glutamine, zinc, multivitamins)
	N-acetylcysteine

Hb F, Fetal hemoglobin.
[a]See text for specific indications and limitations.
[b]Best data from thalassemia patient experience.
[c]Risks minimal; therefore, it is generally done.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

acute/chronic kidney disease, and ophthalmologic complications.
- Referral to an ophthalmologist for an annual dilated retinal examination beginning at 10 yr of age.

PEARLS & CONSIDERATIONS

COMMENTS

- The average life span of individuals with sickle cell trait is similar to that of the general population. It may be associated with hematuria, often painless, and rhabdomyolysis under extreme conditions. Chronic pain and acute pain are not typical of sickle cell trait. It is also associated with a higher incidence of renal medullary cancer.
- Regular immunizations, especially pneumococcal vaccination, are recommended. The prophylactic administration of penicillin soon after birth and the timely administration of pneumococcal and *Haemophilus influenzae* type b vaccines have resulted in a significant decline in the incidence of these infections. The heptavalent conjugated pneumococcal vaccine (Prevnar) should be administered from 2 mo of age. The 23-valent unconjugated pneumococcal vaccine (Pneumovax) is given from age 2 yr and can be boosted once 3 yr later. Influenza vaccination can be given after 6 mo of age.
- Pulmonary hypertension is a complication of chronic hemolysis and is associated with a high risk of death. It can be detected by Doppler echocardiography in more than 30% of adult patients with sickle cell disease. Cardiac catheterization will confirm the diagnosis. It is resistant to hydroxyurea therapy.
- Metformin increases fetal hemoglobin (HbF) levels in patients with SCD. A recent study revealed that metformin use in SCD patients with diabetes is associated with fewer episodes of consequential SCD complications and with lower health care utilization.[2]

BASIC INFORMATION

DEFINITION

Silicosis is a spectrum of lung disease attributable to the inhalation of silica (silicon dioxide) in crystalline form.

SYNONYM

Pneumoconiosis caused by silica

ICD-10CM CODE

J62.8 Pneumoconiosis due to other dust containing silica

EPIDEMIOLOGY & DEMOGRAPHICS

- Occupational disease affecting men and women involved in gathering, milling, processing, or using silica-containing rock or sand. Jobs that can lead to silicosis are described in Box 1.
- According to the Occupational Safety and Health Administration (OSHA), an estimated 200,000 miners and 1.7 million others have experienced an occupational exposure to silica.
- African Americans have a seven times greater rate of developing silicosis compared to whites at the same level of exposure. The annual number of silicosis deaths declined 40% from 185 in 1999 to 111 in 2013, but the decline appears to have leveled off during 2010 to 2013, according to the Centers for Disease Control and Prevention.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- There are three patterns of silicosis: Acute, chronic, and accelerated. The chronic form can be further subdivided in chronic simple silicosis and chronic complicated silicosis (progressive massive fibrosis).
- Acute silicosis is also known as silicoproteinosis. Develops several wk to <5 yr after silica exposure. Presents with rapid onset of cough, weight loss, fatigue, and pleuritic chest pain.
- Chronic silicosis is the most common clinical presentation, and onset occurs after decades of repeated exposure. It has two types:
  1. Simple silicosis, which may be asymptomatic, with the only manifestation being an abnormal chest radiograph. Latency period is 10 to 20 yr and progression to massive fibrosis is rare.
  2. Progressive massive fibrosis characterized by radiographic progression and resulting fibrosis.
- Accelerated silicosis may have an initial asymptomatic phase followed by rapidly increasing frequency of symptoms parallel with worsening radiographic abnormalities. Develops <10 yr after initial high-level exposure.

BOX 1 Jobs That Can Lead to Silicosis

Mining: Surface or underground mining (tunneling)
Milling: Ground silica for abrasives and filler
Quarrying
Sandblasting (e.g., of buildings, preparing steel for painting)
Pottery; ceramic or clay work
Grinding, polishing using silica wheels
Stone work: Strong fabrication, especially with engineered stone.
Foundry work: Grinding, molding, chipping
Refractory brick work
Glass making: To polish and as an abrasive
Boiler work: Cleaning boilers
Manufacture of abrasives

From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

ETIOLOGY

- Silica particles are ingested by alveolar macrophages, which in turn release oxidants causing cell injury and cell death, attract fibroblasts, and activate lymphocytes, increasing immunoglobulins in the alveolar space.
- Hyperplasia of alveolar epithelial cells occurs.
- Collagen accumulates in the interstitium.
- Neutrophils also accumulate and secrete proteolytic enzymes, which leads to tissue destruction and emphysema.
- Silica dust may be carcinogenic (not proven).
- Exposure to silicosis predisposes to tuberculosis.
- Some patients develop rheumatoid silicotic pulmonary nodules and may have arthritic symptoms of rheumatoid arthritis (Caplan syndrome). Scleroderma has also been associated with silicosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other pneumoconiosis, berylliosis, hard metal disease, asbestosis
- Sarcoidosis
- Tuberculosis
- Interstitial lung disease
- Hypersensitivity pneumonitis
- Lung cancer
- Langerhans cell granulomatosis (histiocytosis X)
- Granulomatous pulmonary vasculitis

FIG. 1 Simple silicosis. There are multiple small (2- to 4-mm) nodules distributed throughout the lungs with an upper lobe predominance. (From McLoud TC: *Thoracic radiology: the requisites,* St Louis, 1998, Mosby.)

WORKUP

- History of occupational exposure
- Chest radiograph (Fig. 1)

Acute silicosis:

- Chest radiograph demonstrates bilateral, diffuse ground-glass opacities.
- Chest CT demonstrates diffuse nodular and patchy consolidative opacities with enlargement of hilar lymph nodes.
- Milky and lipoproteinaceous effluent is seen on bronchoalveolar lavage (BAL).
- Lung biopsy is not necessary in the setting of a definite exposure history.
- Exclusion of other causes like pulmonary edema, alveolar hemorrhage, and pulmonary alveolar proteinosis is necessary.

Chronic silicosis:

- Chest radiograph demonstrates multiple small, rounded opacities (<10 cm in diameter) distributed in the upper lung zones.
- Progressive massive fibrosis (PMF) refers to coalescence of the nodules of chronic silicosis with calcified hilar adenopathy.
- Pulmonary function tests (PFT) show mixed obstructive and restrictive defect.
- High resolution CT scan (HRCT), bronchoscopy, and lung biopsies have limited diagnostic role unless atypical radiographic features are noted.

Accelerated silicosis:

- Radiographic pattern is that of simple silicosis, although development of radiographic abnormalities is more rapid. This has greater risk for PMF.

TREATMENT

- Treatment is symptomatic (supplemental O_2 for hypoxemia, bronchodilators, antibiotics for infections).
- Prevention (industrial hygiene).
- Smoking cessation.
- Vaccination against influenza and pneumococcus.
- Whole-lung lavage may have a role in acute silicoproteinosis.
- Treatment of associated tuberculosis if present.
- Consider lung transplant for patients who develop chronic respiratory failure.
- Once patients progress to fibrosis, no therapies can alter the course of the disease.

ASSOCIATED COMPLICATIONS

Silicosis is associated with increased risk of mycobacterial infections, including tuberculosis, chronic necrotizing aspergillosis, lung cancer, rheumatic disorders, and chronic airflow obstruction.

Silicosis (Patient Information)

AUTHORS: **Javeryah Safi, MD,** and **Samaan Rafeq, MD**

BASIC INFORMATION

DEFINITION

Sinusitis is inflammation of the mucous membranes lining one or more of the paranasal sinuses. The various presentations are:

- Acute sinusitis: Infection lasting <4 wk, with complete resolution of symptoms.
- Subacute infection: Lasts from 4 to 12 wk, with complete resolution of symptoms.
- Recurrent acute infection: Episodes of acute infection lasting <30 days, with resolution of symptoms, which recur at intervals at least 10 days apart.
- Chronic sinusitis: Inflammation of the paranasal sinuses and nasal cavities lasting >12 wk, with persistent upper respiratory symptoms. It accounts for 1% to 2% of total physician encounters.
- Acute bacterial sinusitis superimposed on chronic sinusitis: New symptoms that occur in patients with residual symptoms from prior infection(s). With treatment, the new symptoms resolve but the residual ones do not.

SYNONYM

Rhinosinusitis: Sinusitis is almost always accompanied by inflammation of the nasal mucosa; thus it is now the preferred term.

ICD-10CM CODES

J32.9	Chronic sinusitis, unspecified
J01.90	Acute sinusitis, unspecified
J01.00	Acute maxillary sinusitis, unspecified
J01.01	Acute recurrent maxillary sinusitis
J01.10	Acute frontal sinusitis, unspecified
J01.11	Acute recurrent frontal sinusitis
J01.20	Acute ethmoidal sinusitis, unspecified
J01.21	Acute recurrent ethmoidal sinusitis
J01.30	Acute sphenoidal sinusitis, unspecified
J01.31	Acute recurrent sphenoidal sinusitis
J01.80	Other acute sinusitis
J01.81	Other acute recurrent sinusitis
J01.91	Acute recurrent sinusitis, unspecified
J32.0	Chronic maxillary sinusitis
J32.1	Chronic frontal sinusitis
J32.2	Chronic ethmoidal sinusitis
J32.3	Chronic sphenoidal sinusitis
J32.8	Other chronic sinusitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Seems to correlate with the incidence of upper respiratory tract infections and higher in women than men; 30 million cases a yr in the U.S.

PEAK INCIDENCE:

- Fall, winter, spring: September through March
- In adults: Greatest incidence between 45 and 74 yr of age
- Approximately 6% to 7% of children presenting with respiratory symptoms have acute sinusitis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients often give a history of a recent upper respiratory illness with some improvement, then a relapse
- Mucopurulent secretions in the nasal passage:
  1. Purulent nasal and postnasal discharge lasting 7 to 10 days
  2. Facial tightness, pressure, or pain
  3. Nasal obstruction
  4. Headache
  5. Decreased sense of smell
  6. Purulent pharyngeal secretions, brought up with cough, often worse at night
- Erythema, swelling, and tenderness over the infected sinus in a small proportion of patients:
  1. Diagnosis cannot be excluded by the absence of such findings.
  2. These findings are not common, and do not correlate with number of positive sinus aspirates.
- Intermittent low-grade fever in about half of adults with acute bacterial sinusitis
- Toothache is a common complaint when the maxillary sinus is involved
- Periorbital cellulitis and excessive tearing with ethmoid sinusitis:
  1. Orbital extension of infection: Chemosis, proptosis, impaired extraocular movements
- Characteristics of acute sinusitis in children with upper respiratory tract infections:
  1. Persistence of symptoms
  2. Cough
  3. Bad breath
- Symptoms of chronic sinusitis (may or may not be present):
  1. Nasal or postnasal discharge
  2. Fever
  3. Facial pain or pressure
  4. Headache
- Nosocomial sinusitis is typically seen in patients with nasogastric tubes or nasotracheal intubation

ETIOLOGY

- Each of the four paranasal sinuses is connected to the nasal cavity by narrow tubes (ostia), 1 to 3 mm in diameter; these drain directly into the nose through the turbinates. The sinuses are lined with a ciliated mucous membrane (mucoperiosteum).
- Acute viral infection:
  1. Infection with the common cold or influenza
  2. Mucosal edema and sinus inflammation
  3. Decreased drainage of thick secretions/obstruction of the sinus ostia
  4. Subsequent entrapment of bacteria
     a. Multiplication of bacteria
     b. Secondary bacterial infection
- Other predisposing factors:
  1. Tumors
  2. Polyps
  3. Foreign bodies
  4. Congenital choanal atresia
  5. Other entities that cause obstruction of sinus drainage
  6. Allergies
  7. Asthma
- Dental infections lead to maxillary sinusitis.
- Viruses recovered alone or in combination with bacteria (in 16% of cases):
  1. Rhinovirus
  2. Coronavirus
  3. Adenovirus
  4. Parainfluenza virus
  5. Respiratory syncytial virus
- The principal bacterial pathogens in sinusitis are *Streptococcus pneumoniae,* nontypable *Haemophilus influenzae,* and *Moraxella catarrhalis.*
- In the remainder of cases *Streptococcus pyogenes, Staphylococcus aureus,* beta-hemolytic streptococci, and mixed anaerobic infections (*Peptostreptococcus, Fusobacterium, Bacteroides, Prevotella* spp.) are found.
- Infection is polymicrobial in about one third of cases.
- Anaerobic infections are seen more often in cases of chronic sinusitis and in cases associated with dental infection; anaerobes are unlikely pathogens in sinusitis in children.
- Fungal pathogens are isolated with increasing frequency in immunocompromised patients but remain uncommon pathogens in the paranasal sinuses. Fungal pathogens include *Phaeohyphomycosis, Aspergillus, Pseudallescheria, Sporothrix, and Zygomycetes spp.*
- Nosocomial infections: Occur in patients with nasogastric tubes, nasotracheal intubation, cystic fibrosis, and immunocompromised state.
  1. *S. aureus* (including MRSA)
  2. *Pseudomonas aeruginosa*
  3. *Klebsiella pneumoniae*
  4. *Enterobacter* spp.
  5. *Proteus mirabilis*
- Organisms typically isolated in chronic sinusitis:
  1. *S. aureus*
  2. *S. pneumoniae*
  3. *H. influenzae*
  4. *P. aeruginosa*
  5. Anaerobes

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Temporomandibular joint disease
- Migraine headache
- Cluster headache
- Dental infection
- Trigeminal neuralgia
- Allergic rhinitis
- Drugs (cocaine, decongestant overuse)
- Gastroesophageal reflux disease
- Wegener granulomatosis
- Cystic fibrosis

WORKUP

- The diagnosis is generally based on clinical signs and symptoms (purulent rhinorrhea and facial pain). Radiologic tests and cultures are not recommended initially and should be considered only when treatment is ineffective and sinusitis persists.
- In the normal healthy host, the paranasal sinuses should be sterile. Although the contiguous structures are colonized with bacteria and likely contaminate the sinuses, the mucociliary lining functions to remove these bacteria.
- Gold standard for diagnosis: Recovery of bacteria in high-density $\geq 10^4$ colony-forming

units/ml from a paranasal sinus, in the setting of a patient with history of upper respiratory infection and symptoms persisting for 7 to 10 days. Sinus aspiration is the best method for obtaining cultures; however, it must be performed by an otorhinolaryngologist and is not practical for the primary care practitioner. Therefore, most diagnoses are based on the clinical history and presentation, possibly supported by radiologic evaluations.

1. Overall, standard radiographs are of limited use in diagnosis, although negative films are strong evidence against the diagnosis
2. CT scans:
   a. Much more sensitive than plain radiographs in detecting acute changes and disease in the sinuses
   b. Recommended for patients requiring surgical intervention, including sinus aspiration; it is a useful adjunct to guide therapy
3. Transillumination:
   a. Used for diagnosis of frontal and maxillary sinusitis
   b. Absence of light transmission indicates that sinus is filled with fluid
   c. Dullness (decreased light transmission) is less helpful in diagnosing infection
4. Endoscopy:
   a. Used to visualize secretions coming from the ostia of infected sinuses
   b. Culture collection via endoscopy often contaminated by nasal flora; not nearly as good as sinus puncture
5. Sinus puncture:
   a. Gold standard for collecting sinus cultures
   b. Generally reserved for treatment failures, suspected intracranial extension, and nosocomial sinusitis

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

To help promote sinus drainage:

- Air humidification with vaporizers (for steam) or humidifiers (for a cool mist)
- Application of hot, wet towel over the face
- Sipping hot beverages
- Hydration

ACUTE GENERAL Rx

- Sinus drainage:
  1. Nasal vasoconstrictors, such as phenylephrine nose drops, 0.25% or 0.5%.
  2. Topical decongestants should not be used for more than a few days because of the risk of rebound congestion.
  3. Systemic decongestants.
  4. Corticosteroids: Nasal or systemic corticosteroids, such as nasal beclomethasone. Oral corticosteroids combined with antibiotics may be associated with modest benefit for short-term relief of symptoms in adults with severe symptoms of acute sinusitis compared with antibiotics alone. Oral corticosteroids as monotherapy are not associated with improved clinical outcomes in adults with clinically diagnosed acute sinusitis.[1]
  5. Nasal irrigation, with hypertonic or normal saline (saline may act as a mild vasoconstrictor of nasal blood flow).
  6. Use of antihistamines has no proven benefit, and the drying effect on the mucous membranes may cause crusting, which blocks the ostia, thus interfering with sinus drainage.
- Analgesics, antipyretics

Antimicrobial therapy:

- Most cases of acute sinusitis have a viral cause and will resolve within 2 wk without antibiotics.
- Current treatment recommendations favor symptomatic treatment for those with mild symptoms. 85% of persons have a reduction or resolution of symptoms within 7 to 15 days without antibiotic therapy. Physicians grossly overprescribe antibiotics for presumed bacterial sinusitis despite a much higher prevalence of viral infections.
- Antibiotics should not be prescribed for mild to moderate sinusitis within the first wk of illness. They should be reserved for those with persistent symptoms for more than 10 days, high fever and purulent nasal discharge or facial pain lasting for at least 3 consecutive days, or worsening symptoms after a typical viral illness lasting >5 days that had initially improved ("double sickening").
- Antibiotic therapy is usually empiric, targeting the common pathogens:
  1. First-line antibiotics in children include amoxicillin or amoxicillin/clavulanate. For adults amoxicillin/clavulanate or doxycycline is first-line agent, with quinolones (levofloxacin or moxifloxacin) reserved as second-line agents unless patient is penicillin allergic.
  2. Second-line antibiotics include the newer macrolides: clarithromycin, and oral cephalosporins: cefuroxime axetil, cefprozil, cefaclor, loracarbef, but high rate of resistance of *S. pneumoniae* is a concern with these agents as is *H. influenzae* resistance with TMP-SMX and azithromycin such that they should no longer be used as first-line agents.
  3. For patients with uncomplicated acute sinusitis, the less expensive first-line agents appear to be as effective as the costlier second-line agents.
- Hospitalization and IV antibiotics may be required for more severe infection and those with suspected intracranial complications. Broader-spectrum antibiotic coverage may be indicated in severe cases, to cover for MRSA, *Pseudomonas*, and fungal pathogens.
- Duration of therapy generally 5 to 7 days in adults rather than 10 to 14 days as recommended in the past.
  1. Optimal duration of treatment in children varies from 10 to 28 days.

Surgery:

- Surgical drainage indicated
  1. If intracranial or orbital complications suspected
  2. Many cases of frontal and sphenoid sinusitis
  3. Chronic sinusitis recalcitrant to medical therapy
- Surgical debridement imperative in the treatment of fungal sinusitis

Complications:

- Untreated, sinusitis may lead to a number of serious, life-threatening complications.
- Intracranial complications include meningitis, brain abscess, and epidural and subdural empyema.
- Intracranial sequelae are more common with frontal and ethmoid infections.
- Extracranial complications include orbital cellulitis, blindness, orbital abscess, osteomyelitis.
- Extracranial sequelae are more commonly seen with ethmoid sinusitis.

CHRONIC Rx

- Chronic sinusitis: Evidence supports daily high-volume saline irrigation with topical corticosteroid therapy as a first-line therapy for chronic sinusitis. A short course of systemic corticosteroids (1 to 3 wk), short course of doxycycline (3 wk), or a leukotriene antagonist may be considered in patients with nasal polyps. A prolonged course (3 mo) of macrolide antibiotic may be considered for patients without polyps.
- Dupilumab (Dupixent), a monoclonal antibody that targets interleukin (IL)-4 and -13 was recently FDA approved for chronic rhinosinusitis with nasal polyps (CRSwNP). Cost is a limiting factor.
- Surgical intervention may be necessary in nonresponders.

REFERRAL

- To infectious disease specialist if failure to respond to initial therapy
- To otorhinolaryngologist for:
  1. Failure to respond to therapy
  2. Suspected fungal infection
  3. Suspected intracranial or orbital complications

Sjögren Syndrome PTG ALG

BASIC INFORMATION

DEFINITION

Sjögren syndrome (SS) is a chronic autoimmune disorder that targets exocrine glands. It is characterized by lymphocytic and plasma cell infiltration and destruction of salivary, lacrimal, and parotid glands, resulting predominantly in dry eyes and dry mouth, but it can affect other organ systems as well.

Primary and secondary forms have been described:

- Primary: Dry mouth (xerostomia) and dry eyes (xerophthalmia) develop as isolated entities. Is immunogenetically associated with HLA-DRB1*0301 and DRB1*1501 and serologically associated with antibodies to Ro/SS-A and La/SS-B.
- Secondary: Associated with other autoimmune connective tissue diseases. The immunogenetic and serologic findings are usually those of the accompanying disease (e.g., HLA-DR4 if associated with RA).

SYNONYMS

SS
Sicca syndrome
Keratoconjunctivitis sicca
Sicca complex
Dry eye syndrome/dysfunctional tear syndrome

ICD-10CM CODES

M35.00	Sicca syndrome, unspecified
M35.01	Sicca syndrome with keratoconjunctivitis
M35.02	Sicca syndrome with lung involvement
M35.03	Sicca syndrome with myopathy
M35.04	Sicca syndrome with tubulo-interstitial nephropathy
M35.09	Sicca syndrome with other organ involvement

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 4 per 100,000; of these cases, 70% had primary SS.

PREVALENCE: Prevalence is 0.2% to 2.7% of population; secondary SS is also common and can affect up to 19% of patients with systemic lupus erythematosus (SLE) and 26% to 31% of rheumatoid arthritis (RA) and scleroderma patients.

PREDOMINANT SEX: Female:male ratio is approximately 10:1.

PREDOMINANT AGE: Peak incidence is the fourth and fifth decade, but can occur in all ages. Rarely reported in children.

RISK FACTOR: Seen in all races/ethnicities, but more common in Caucasians.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

SS is one of the most common autoimmune diseases and should be considered in any patient with unexplained symptoms and a positive antinuclear antibody.

2016 American College of Rheumatology/European League Against Rheumatism classification criteria for primary SS: A score of >4 when the weights from the criteria are summed:

- Labial salivary gland with focal lymphocytic sialadenitis and focus of >1 foci/4 mm^2—score 3
- Anti-SSA/Ro positive—score 3
- Ocular staining score >5 in at least one eye—score 1
- Schirmer test <5 mm/5 min in at least one eye—score 1
- Unstimulated whole saliva flow rate <0.1 ml/min—score 1

Diagnosis of SS based on the prior diagnostic criteria was presence of at least two of three objective diagnostic tests below:

1. Positive serum levels of anti-SS-A/Ro and/or anti-SS-B/La or a positive rheumatoid factor and antinuclear antibody (ANA) titer of at least 1:320
2. Salivary gland biopsy exhibiting focal sites of inflammation. One or more sites of inflammation per 4 mm^2 are considered to be positive
3. Keratoconjunctivitis sicca with ocular staining score of three or more (the dissipation rate of a specialized dye that is applied to the tear film that bathes the surface of the eye; a score of three or more is considered to be positive)

Manifestations:

- Dry mouth, dry lips (cheilosis), erythema and hyperlobulation of tongue (Fig. E1) and other mucosal surfaces, carious teeth
- Dry eyes (conjunctival injection, corneal ulceration, blurred vision, decreased luster, enlargement of lacrimal glands, and irregularity of the corneal light reflex)
- Salivary gland enlargement (Fig. E2) and dysfunction, with subsequent difficulty in chewing and swallowing food and in speaking without frequent water intake, thickened saliva, and burning sensation in mouth
- Extra-glandular involvement occurs in 50% of patients. There are multiple systemic manifestations associated with SS, which include the following:
  1. Fever/fatigue.
  2. Cutaneous vasculitis may be present, usually of lower extremities.
  3. Skin ulceration, photosensitivity, Raynaud phenomenon.
  4. Dyspareunia and pruritus can occur secondary to vaginal dryness.
  5. Pulmonary involvement includes interstitial lung disease (NSIP, UIP); lymphocytic interstitial pneumonitis (LIP) and cryptogenic organizing pneumonia (COP); chronic obstructive pulmonary disease; fibrosis; and xerotrachea.
  6. Gastrointestinal: Celiac disease, esophageal dysmotility, type I autoimmune hepatitis, primary biliary cirrhosis, and pancreatitis can occur.
  7. Renal manifestations: Type 1 renal tubular acidosis, Fanconi syndrome, glomerulonephritis, and interstitial nephritis.
  8. Neurologic involvement: Peripheral, cranial, or autonomic neuropathy; CNS involvement also possible, cognitive dysfunction ("brain fog").
  9. Musculoskeletal: Arthralgias and myopathy.
  10. Hematologic: Cytopenias, hypergammaglobulinemia, cryoglobulins. Increased lymphoma risk, with 5% to 10% developing non-Hodgkin lymphoma.
  11. RA and other connective tissue diseases are seen commonly with secondary SS.
  12. Autoimmune thyroiditis may be observed in patients with SS.
  13. Pregnancy: Patients with anti-SSA antibodies have an increased risk of delivering a baby with neonatal lupus, with cutaneous manifestations or congenital heart block.

ETIOLOGY

Sjögren syndrome is an autoimmune disorder of unclear etiology. It is associated with certain HLA-DQ and HLA-DR alleles. It has been postulated that viral agents (e.g., hepatitis C and Epstein-Barr virus) may trigger the clinical manifestations. The pathogenesis involves a complex interplay of several factors, including genetic and epigenetic controls of immune homeostasis and gene expression, age, gender, and environmental insults.

Over 90% of the infiltrating cells are CD4+ T lymphocytes with memory phenotype (70%) and B lymphocytes (20%). The remaining 10% are an admixture of plasma cells, CD8+ T lymphocytes, T regulatory cells, natural killer cells, and dendritic cells. Predominantly Th1- and Th17-driven response.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Medication-related dryness (e.g., anticholinergics, antihistamines, diuretics, benzodiazepines, antidepressants)
- Age-related exocrine gland dysfunction
- Mouth breathing, anxiety
- Infections such as viruses, HIV, hepatitis C
- Diabetes mellitus, acromegaly, Type V hyperlipidemia
- Chronic sialadenitis
- Graft-versus-host diseaselg
- G4-related disease
- Ocular herpetic lesions, blepharitis, corneal abrasions, contact lens irritation
- Vitamin A deficiency
- Other: Sarcoidosis, primary salivary hypofunction, radiation injury, amyloidosis
- An algorithm for the diagnosis of SS is provided in Fig. 3

WORKUP

Workup involves ocular and oral examination and laboratory and radiographic testing to demonstrate the following criteria for diagnosis of primary and secondary SS.

- Symptoms and objective signs of ocular dryness:
  1. Schirmer test (Fig. E4): <5 mm wetting per 5 min. (Normal wetting is >15mm in

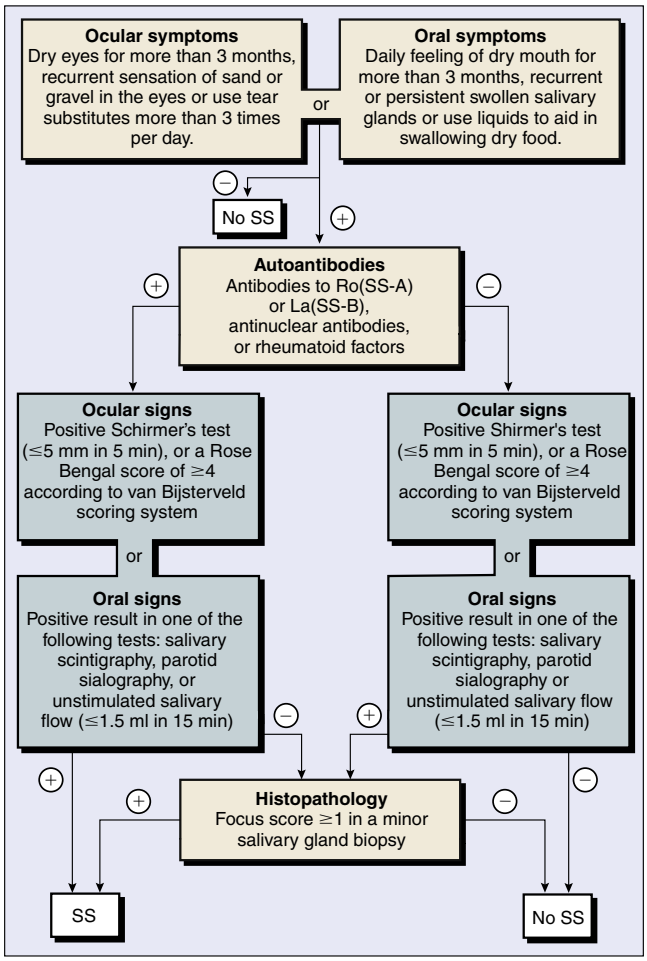

FIG. 3 Suggested algorithm for the diagnosis of Sjögren syndrome. Exclusion criteria include hepatitis C or human immunodeficiency virus infection, sarcoidosis, graft-versus-host disease, preexisting lymphoma, previous head or neck irradiation, and use of anticholinergic drugs. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

5 minutes). There is a 15% false-positive and false-negative rate.
2. Zone-quick diagnostic threads: A sterile cotton thread with pH indicator, phenol red. Yellow turns to red in contact with tears.
3. Positive Rose Bengal stains dead/dying cells.
4. Tear breakup time and tear osmolality measured after instillation of fluorescein.

- Symptoms and objective signs of dry mouth:
  1. Decreased parotid flow using Lashley cups or other methods
  2. Abnormal biopsy result of minor salivary gland (focus score >1 based on average of four assessable lobules)
  3. Sialometry (sensitivity 56%, specificity 81%): Assessment of rate of saliva production in which collection of ≤1.5 ml after two expectorations 15 min apart is considered positive
- Evidence of systemic autoimmune disorder:
  1. Elevated rheumatoid factor (70% to 90% of patients)
  2. Elevated titer of ANA >1:320 (80% of patients)
  3. Presence of anti-SS-A (Ro) (>60% of patients) or anti-SS-B (La) antibodies (40% of patients)

SECONDARY:
- Characteristic signs and symptoms of SS
- Clinical features sufficient to allow a diagnosis of RA, SLE, polymyositis, or scleroderma

LABORATORY TESTS

- Positive ANA (80% of patients) with autoantibodies anti-SS-A and anti-SS-B may be present.
- Additional laboratory abnormalities may include elevated erythrocyte sedimentation rate, anemia, leukopenia, thrombocytopenia, abnormal liver function studies, elevated serum $beta_2$ microglobulin levels, rheumatoid factor (50% to 60%), hypergammaglobulinemia, antibodies to double-stranded DNA (in cases with proteinuria), depressed C3 and C4, and the presence of cryoglobulins (30% of patients).
- A definite diagnosis of SS can be made with a salivary gland biopsy (gold standard) showing focal lymphocytic sialadenitis with focus score of 1 per 4 mm^2 of glandular tissue.
- Salivary gland ultrasound can be done to characterize changes in salivary gland parenchyma (sensitivity 75%, specificity 78%). Diseased gland shows hypoechoic areas with convex borders.
- MRI of the gland shows inhomogeneous parenchyma. Finding generally correlates with biopsy of the gland.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Adequate fluid replacement. Ameliorate skin dryness by gently blotting dry after bathing, leaving a small amount of moisture, and then applying a moisturizer
- Increased environmental moisture by using humidifiers
- Proper oral hygiene (daily topical fluoride use, antimicrobial mouth rinses, and stabilization of oral cavity pH) to reduce the incidence of caries
- Sugar-free chewing gum and sour lemon lozenges to stimulate salivary secretion
- Periodic dental and ophthalmologic evaluations to screen for complications
- Reduce caffeine intake and smoking

GENERAL Rx

- Use artificial tears frequently.

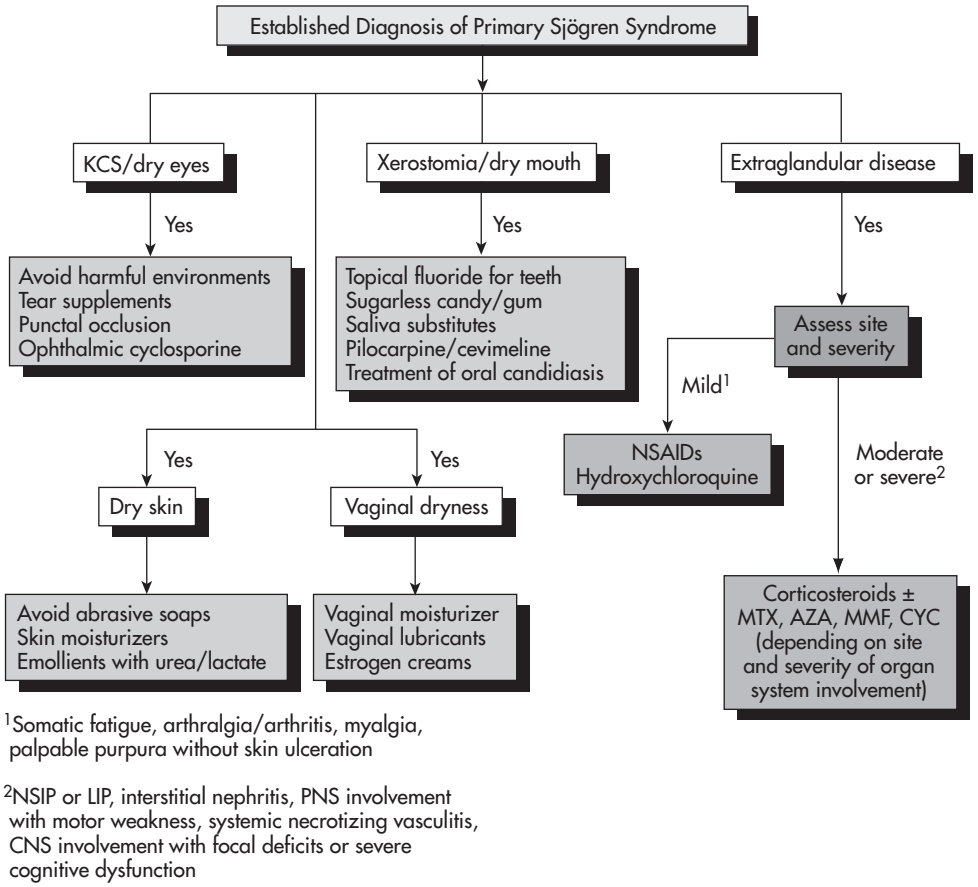

FIG. 5 Treatment algorithm for Sjögren syndrome. The treatment of Sjögren syndrome usually requires a multidisciplinary approach involving rheumatologists, ophthalmologists, dentists/oral surgeons, otolaryngologists, and other subspecialists, depending on the extent of extra-glandular disease. In all cases, it is prudent to minimize the use of medications that can exacerbate the symptoms of dryness, such as antihistamines, antidepressants, muscle relaxers, and other drugs with anticholinergic properties. The treatment of extra-glandular disease is individualized according to the site and severity of organ system involvement. The approaches indicated in the algorithm for the treatment of extra-glandular disease are not supported by evidence from randomized, controlled trials, but rather from expert opinion based on retrospective case series and clinical experience. *AZA,* Azathioprine; *CNS,* central nervous system; *CYC,* cyclophosphamide; *KCS,* keratoconjunctivitis sicca; *LIP,* lymphocytic interstitial pneumonitis; *MMF,* mycophenolate mofetil; *MTX,* methotrexate; *NSAIDs,* nonsteroidal antiinflammatory drugs; *NSIP,* nonspecific interstitial pneumonitis; *PNS,* peripheral nervous system. (From Firestein GS et al: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

- Muscarinic agonists: Pilocarpine (5mg PO QID) or cevimeline (30mg PO TID) can be useful to improve oral dryness.
- Ophthalmic cyclosporine and lifitegrast drops may be useful for dry eyes.
- Hydroxychloroquine alone or in conjunction with methotrexate may be useful for arthralgias and cutaneous manifestations.
- Oral cyclosporine only improves the symptoms of subjective dryness.
- Tumor necrosis factor (TNF) antagonists have not shown benefit in short-duration placebo-controlled trials.
- Rituximab (RTX) has shown some improvement in oral dry mouth symptoms, relieving marked salivary and lacrimal gland swelling in a retrospective review.
- Propionic acid gel can be used for vaginal dryness.
- Systemic manifestations are treated according to symptoms and complications.
- Cyclophosphamide, azathioprine, and mycophenolate mofetil are generally reserved for life-threatening extra-glandular manifestations.
- Fig. 5 describes a treatment algorithm for Sjögren syndrome.

REFERRAL

- Rheumatology referral is generally indicated.
- Referral should be made to an oncologist when lymphoma is suspected.
- During pregnancy, if patient tests positive for SSA/SSB antibody, she should seek consultation with a perinatologist.

PEARLS & CONSIDERATIONS

COMMENTS

- Unusual presentations of SS may occur in association with polymyalgia rheumatica, chronic fatigue syndrome, fever of unknown origin, and inflammatory myositis.
- The most serious complication of primary SS is the development of non-Hodgkin lymphoma and other lymphoproliferative disorders, which occur at a ten- to forty-fourfold increased rate as compared to age-matched controls.
- The presence of parotid gland enlargement, rheumatoid factor, low C4, cryoglobulinemia, lymphopenia, and higher levels of disease activity as measured by EULAR Sjögren Syndrome Disease Activity Index (ESSDAI) predicts a higher lymphoma risk.

BASIC INFORMATION

DEFINITION

The *International Classification of Sleep Disorders, Third Edition,* classifies sleep-disordered breathing disorders into five categories: central sleep apnea syndrome (Table 1), obstructive sleep apnea disorders (OSA), sleep-related hypoventilation disorders, sleep-related hypoxemia disorder, and isolated symptoms and normal variants. The American Academy of *Sleep Medicine* defines OSA as repetitive episodes of upper airway obstruction that occur during sleep and that are typically associated with oxyhemoglobin desaturations.

SYNONYMS

Sleep apnea syndrome
Sleep-disordered breathing
Obstructive sleep apnea syndrome (OSA)
Obstructive sleep apnea–hypopnea syndrome

ICD-10CM CODES

G47.30	Sleep apnea, unspecified
G47.31	Primary central sleep apnea
G47.33	Obstructive sleep apnea (adult) (pediatric)
G47.37	Central sleep apnea in conditions classified elsewhere
G47.39	Other sleep apnea
P28.3	Primary sleep apnea of newborn

EPIDEMIOLOGY & DEMOGRAPHICS

OSA is a common disease in the U.S. Data from the Wisconsin Cohort Study indicated that the current prevalence of moderate to severe sleep-disordered breathing (apnea-hypopnea index, measured as events/hour, ≥15) is 10% among 30- to 49-yr-old men; 17% among 50- to 70-yr-old men; 3% among 30- to 49-yr-old women; and 9% among 50- to 70-yr-old women. The prevalence of OSA with associated excessive daytime somnolence is approximately 3% to 7% in adult men and 2% to 5% in adult women.[2] The prevalence seems to be higher in obese and hypertensive patients. The prevalence of OSA in the general pediatric population is estimated to be 1% to 6%. However, in obese children and adolescents, OSAH is reported to occur in 19% to 61%. Risk factors include obesity, craniofacial and upper airway abnormalities, and retrognathia, while family history of OSA, current tobacco smoking, nasal congestion, and diabetes are clinical associations. There are an estimated 24 million persons in the U.S. who remain undiagnosed.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Many patients are unaware that their breathing is affected and may not visit a physician for evaluation. Others may not consider sleepiness a relevant topic to discuss with their health care provider.
- Nocturnal symptoms, including gastroesophageal reflux symptoms, nocturia, and angina pectoris
- Snoring (potentially loud, habitual, and bothersome to others)
- Witnessed apneas that often interrupt snoring and end with a snort
- Gasping, choking, or smothering sensations that arouse the patient from sleep
- Restless sleep associated with frequent arousals
- Daytime symptoms:
  1. Nonrestorative sleep
  2. Not feeling refreshed upon awakening
  3. Morning headache
  4. Dry mouth or throat upon awakening
  5. Excessive daytime sleepiness, typically during quiet activities
  6. Daytime fatigue or tiredness
  7. Problems with memory, concentration, and cognitive function, especially with executive functioning
  8. Easily angered, short tempered, and inattentive
  9. Hyperactivity in children
  10. Symptoms of fibromyalgia
  11. Cognitive decline (older population)
- Obesity (body mass index >30 kg/m2). A 10% increase in weight predicts a sixfold increase in the likelihood of developing clinically significant OSA
- Insulin resistance or type 2 diabetes mellitus
- Mood swings, irritability, anxiety, and/or depression
- Decreased libido and/or impotence
- Neck circumference (surrogate marker for central obesity) of >43 cm (17 in) in men and >37 cm (15 in) in women
- Erythematous oropharynx because of snoring
- Adenotonsillar hypertrophy, excessive soft tissue, high-arched hard palate, pendulous uvula, prominent tongue, large degree of overjet, and retrognathia or micrognathia can be present
- Narrowing of lateral airway walls is independent predictor of OSA in men but not women
- Craniofacial skeletal abnormalities can lead to OSA, particularly among children and nonobese adults
- Systemic hypertension (HTN)
- Pulmonary HTN
- Family history of OSA increases risk with each additional close family member further increasing odds
- Table 2 summarizes clinical characteristics of patients with sleep apnea

TABLE 1 Pathophysiologic Classification of Central Sleep Apneas

Physiologic	Pathologic
• Sleep transition • Phasic REM	Nonhypercapnic • Medical condition related 1. Congestive heart failure 2. Poststroke 3. ESRD 4. PAH 5. Atrial fibrillation • High altitude • Idiopathic Hypercapnic • Congenital central hypoventilation syndrome • Primary chronic alveolar hypoventilation syndromes • Other CNS disorders associated with CSA 1. Encephalitis, tumors, strokes 2. Anatomic abnormalities 3. Neurodegenerative disorders • Muscular and PNS disorders associated with CSA (selected examples) 1. Muscular dystrophies 2. Acid maltase deficiency 3. Charcot-Marie-Tooth disease and other neuropathies 4. Postpolio syndrome 5. Myasthenia gravis Disintegrative (e.g., brainstem injury, opioid induced) CSA with OSA or upper airway disorders (including treatment emergent CSA)

CNS, Central nervous system; *CSA,* central sleep apnea; *ESRD,* end-stage renal disease; *OSA,* obstructive sleep apnea; *PAH,* pulmonary arterial hypertension, *PNS,* peripheral nervous system; *REM,* rapid eye movements.
From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.

ETIOLOGY

- Narrowing of upper airway as a result of obesity or increased peripharyngeal fat deposition, retrognathia and/or micrognathia, adenotonsillar hypertrophy, macroglossia, or neuromuscular weakness (Fig. E1)
- Upper airway muscular weakness as a result of neuromuscular disorders, primary CNS disorders (e.g., stroke), or metabolic disorders
- Other diseases associated with the development of OSAH (e.g., hypothyroidism, acromegaly)
- Fig. E2 illustrates the pathophysiologic consequences of OSA

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anemia
- Anxiety or panic disorder
- Behaviorally induced insufficient sleep syndrome
- Cardiac or heart disease
- Central sleep apnea
- Circadian rhythm disorder

TABLE 2 Clinical Characteristics of Patients with Sleep Apnea

Central		
Nonhypercapnic	**Hypercapnic**	**Obstructive**
Insomnia	Daytime sleepiness Morning headache	Daytime sleepiness
Mild intermittent snoring	Snoring	Prominent snoring
Awakenings (choking, dyspnea)	Respiratory failure	Witnessed apneas, gasping
Normal body habitus	Normal or obese Polycythemia Cor pulmonale	Commonly obese Upper airway narrowing

From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.

Epworth Sleepiness Scale

Situation	Score
Sitting and reading	
Watching TV	
Sitting inactive in public place	
Passenger in car	
Lying down to rest in afternoon	
Sitting talking to someone	
Sitting after lunch without alcohol	
In a car, stopped for minutes in traffic	
Total (normal #10)	

Dozing

0 = Never

1 = Slight chance

2 = Moderate chance

3 = High chance

FIG. 3 The Epworth Sleepiness Scale. This instrument asks patients about their likelihood of dozing in eight different situations over the past mo. (From Mason RJ et al: *Murray and Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.)

- Depression
- Drug or alcohol abuse
- Gastroesophageal reflux
- Hypothyroidism
- Idiopathic hypersomnia with long or short sleep time
- Inadequate sleep hygiene
- Insomnia
- Medication effect
- Narcolepsy
- Nocturnal asthma
- Nocturnal gastroesophageal reflux
- Nocturnal seizures
- Obesity-hypoventilation syndrome
- Parasomnias
- Parkinson disease
- Periodic limb movement disorder
- Primary snoring
- Pulmonary or lung disease
- Restless legs syndrome
- Shift work sleep disorder
- Sleep fragmentation (multiple causes)

WORKUP

- Evaluation should include questions about snoring, witnessed apneas, gasping or choking episodes, restless sleep, and excessive daytime sleepiness. Fig. 3 describes the Epworth Sleepiness Scale, an instrument that evaluates the likelihood of dozing in eight different situations in the preceding 30 days. The Berlin Questionnaire and the STOP-BANG screening test are also widely used and well validated screening instruments.
- Mood swings and personality changes should be addressed.
- Job performance and difficulty driving or previous motor vehicle accidents related to excessive daytime sleepiness should be discussed.
- Additional concerns include morning dry mouth/throat, morning headaches, alcohol intake, weight gain, mood or personality changes.
- A thorough drug history should be performed that includes the use of narcotics, muscle relaxants, and sedatives.
- A family history should target the presence of OSA.
- Physical exam is frequently normal in patients with OSA except for the presence of obesity, enlarged neck circumference, and possibly HTN.
- OSAH is confirmed by nocturnal polysomnography (PSG), which is the gold standard for diagnosis (Fig. 4). The PSG should be performed during the patient's typical sleeping hours; it should include all stages of sleep in the supine position. A growing trend is evaluating patients with home testing rather than in-lab polysomnography, although this is not yet approved for routine pediatric testing.
- The severity of the OSA is determined by the apnea-hypopnea index (AHI) (Table 3), which is derived from the total number of apneas and hypopneas divided by the total sleep time.
- Recommended severity cutoff levels for the AHI in adult patients are as follows:
  1. Mild: 5 to 15 respiratory events per hour (with symptoms)
  2. Moderate: 15 to 30 respiratory events per hour
  3. Severe: >30 respiratory events per hour
- In children, the thresholds for severity of OSA are lower compared to adults.
- Criteria for the treatment of mild OSAH often require symptoms, including excessive daytime sleepiness, cardiovascular disease, HTN, and mood swings.
- In certain patients, portable sleep studies or pulse oximetry may be an effective alternative to PSG for evaluation of OSA.

LABORATORY TESTS

- Arterial blood gas testing should be performed if a patient has suspected pulmonary HTN or cor pulmonale to rule out daytime hypoxemia and/or hypercapnia.
- Thyroid studies should be obtained if thyroid dysfunction is suspected.
- Fasting glucose level is recommended because OSA increases risk of diabetes mellitus independent of other risk factors.
- Complete blood count is helpful to look for anemia; iron studies if anemia is detected

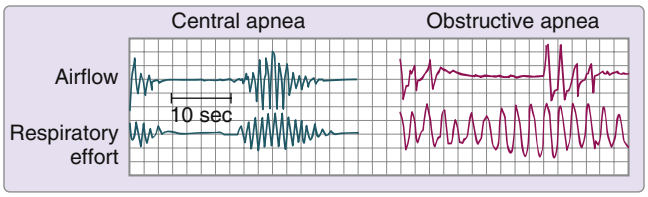

FIG. 4 Central and obstructive sleep apnea: The relationship between airflow and respiratory effort in central and obstructive apnea. During central apnea, cessation of airflow occurs without associated ventilatory effort. Respiratory effort is present during an obstructive apnea. (From Wellman A, White DP: Central sleep apnea and periodic breathing. In Kryger M, Dement W [eds]: *Principles and practice of sleep medicine,* ed 5, Philadelphia, 2011, WB Saunders, 1140-1152.)

TABLE 3 Definitions*

Events

Apnea: Cessation of breathing lasting 10 seconds or longer. Obstructive—continued respiratory effort with paradoxical motion of rib cage and abdomen; central—absent respiratory effort.

Hypopnea: Different definitions used. Two alternative definitions are part of the scoring criteria advanced by the American Academy of Sleep Medicine:

1. Score a hypopnea if all of the following are present:
   a. Nasal pressure signal excursions; drop ≥30% of baseline for at least 10 seconds.
   b. There is a ≥4% desaturation from pre-event baseline.
   c. At least 90% of the event's duration must meet the amplitude reduction of criteria for hypopnea.
2. Score a hypopnea if all of the following are present:
   a. Nasal pressure signal excursions; drop ≥50% of baseline for at least 10 seconds.
   b. There is a ≥3% desaturation from pre-event baseline *or* the event is associated with an arousal. (The latter does not require a desaturation.)
   c. At least 90% of the event's duration must meet the amplitude reduction of criteria for hypopnea.
3. *Respiratory Effort–Related Arousal (RERA):* Pattern of progressively more negative esophageal pressure terminated by a sudden change in pressure to a less negative level and an arousal; events last 10 seconds or longer.

Metrics of Severity

Apnea-Hypopnea Index: Average number of apneas plus hypopneas per hour of sleep.
Respiratory Disturbance Index: Average number of apneas plus hypopneas plus RERAs per hour of sleep.

Consensus Definitions of Severity

Normal: <5 episodes/hr
Mild sleep apnea: ≥5 and <15 episodes/hr
Moderate sleep apnea: ≥15 and <30 episodes/hr
Severe sleep apnea: ≥30 episodes/hr

Concept of Sleep Apnea Syndrome

Sleep-disordered breathing with complaint of excessive sleepiness

*See also American Academy of Sleep Medicine.
From Mason RJ et al: *Murray and Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.

and ferritin level if concomitant restless legs syndrome is present.
- Pulmonary function testing if lung disease is suspected or to assess severity of neuromuscular disease in that patient population.
- 12-lead electrocardiogram (ECG) or echocardiogram is indicated if cardiac dysfunction is suspected.

IMAGING STUDIES

- Plain radiography of the neck can be helpful to assess the soft tissues of patients with anatomic abnormalities.
- Chest x-ray if lung disease is suspected.

Rx TREATMENT

Fig. 5 illustrates medical therapies for obstructive sleep apnea stratified by mechanisms targeted.

NONPHARMACOLOGIC THERAPY

- Behavioral modifications:
  1. Weight loss in overweight and obese patients. Evidence exists that weight loss is effective for reducing the severity of OSA, and if significant, it may potentially allow some patients to discontinue continuous positive airway pressure (CPAP) therapy.
  2. 10% weight gain predicted an approximate 32% increase in the AHI and sixfold increase in the odds of developing moderate to severe sleep disordered breathing.
  3. 10% weight loss predicted a 26% decrease in the AHI.
  4. Weight loss with bariatric surgery may improve OSA in some patients, but its definitive role remains unclear. In a recent trial in obese patients with OSA, bariatric surgery compared with conventional weight loss therapy did not statistically reduce AHI despite major differences in weight loss.
  5. Exercise without weight loss may improve OSA.
  6. Avoid alcohol for 4 to 6 hours before bedtime.
  7. Avoid narcotics, muscle relaxants, and sedating medications.
  8. Sleep hygiene training, especially avoidance of sleep deprivation.
  9. Avoid or reduce supine sleeping positions.
  10. Avoid medications that may worsen OSA.
- Medical treatment:
  1. CPAP is the primary therapy for OSA. It delivers a constant airway pressure that serves as a pneumatic splint relieving upper airway obstruction.
  2. Other methods of delivering positive pressure include:
     a. Bilevel positive airway pressure (BiPAP), which delivers predetermined inspiratory and expiratory airway pressures.
     b. Auto-titrating positive airway pressure (APAP), which increases or decreases the level of pressure in response to change in airflow, vibratory snoring, or changes in circuit pressure.
  3. Oral appliances constructed by a reputable and qualified dentist may be effective for the treatment of mild OSA in certain patients, especially those with retrognathia. Mandibular advancement devices (MADs) are a good alternative to CPAP in patients who are unable to tolerate CPAP. Trials have shown that although CPAP is more effective than MADs in reducing AHI (4.5 vs. 11 events/h, respectively), self-reported adherence with use of MADs is higher (6.5 vs. 5.2 h/night for CPAP use). Important health outcomes were similar after 1 mo of optimal MAD and CPAP treatment in patients with moderate-severe OSAH, which may be explained by the greater efficacy of CPAP being offset by inferior compliance relative to MAD, resulting in similar effectiveness. There was no overall difference between MADs and CPAP with respect to improvement in blood pressure, daytime sleepiness, or quality of life.
  4. Optimal treatment of allergic rhinitis should be pursued, including nasal irrigation and direct antiinflammatory therapies.
  5. Symptoms of excessive daytime sleepiness that linger despite good compliance to CPAP may require further investigation or medical therapy with stimulants.
  6. Patients should be considered for surgery if multiple attempts at CPAP therapy have failed and if an oral appliance is not an option. If the patient opts for surgery, ensure that it is performed by a reputable and qualified otolaryngologist and is based on the location of airway collapse.

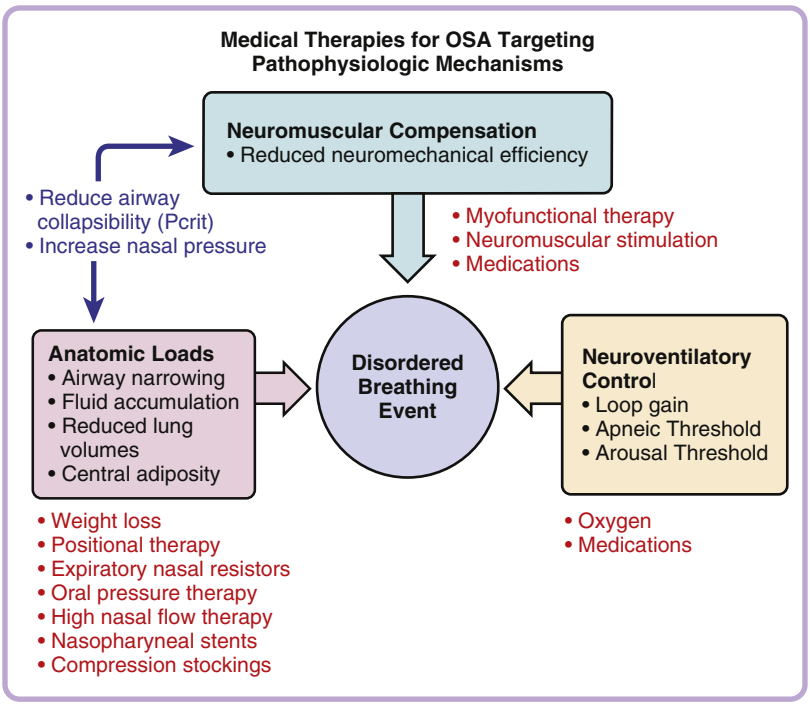

FIG. 5 Medical therapies for obstructive sleep apnea *(OSA)*, stratified by mechanisms targeted. Certain therapies can be considered on the basis of the pathophysiologic mechanisms targeted. OSA is thought to occur as a consequence of increases in anatomic loads on the upper airway, impairments in neuromuscular compensation, or alterations in neuroventilatory control. Traditional therapies such as continuous positive airway pressure (CPAP) use nasal pressure to overcome anatomic loads. By contrast, upper airway surgery or weight loss results in reduced airway collapsibility (Pcrit). Other therapies that may relieve anatomic loads on the upper airway include positional therapy, use of expiratory nasal resistors, oral pressure therapy, nasopharyngeal stenting, and application of compression stockings. Therapies that address impairments in neuromuscular function include myofunctional therapies, use of certain medications, and neuromuscular stimulation. Therapies that may affect neuroventilatory control include use of medications to increase the arousal threshold and supplemental oxygen, which can affect loop gain. (From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.)

- Surgical treatment:
  1. Surgery is done to correct specific anatomic areas of narrowing: nasal, pharyngeal, and tongue base/hypopharynx.
  2. Adenotonsillectomy is often curative for children with OSA.
  3. Nasal septoplasty/turbinectomy should be considered for patients with nasoseptal deformities.
  4. Uvulopalatopharyngoplasty, which involves resection of the uvula and soft palate, is effective for a small number of patients. Predicting which patients will benefit from this surgical treatment is difficult.
  5. Palatal implant surgery and distraction osteogenesis maxillary expansion (DOME) for high-arched palates are other surgical options.
  6. Hypoglossal nerve stimulation (by surgical placement of an implant in the upper chest) helps recruit lingual muscles, reduce pharyngeal collapsibility, and decrease upper airway resistance.
  7. Tracheostomy is typically reserved for patients with very severe OSA who failed medical therapy or who have cor pulmonale.

DISPOSITION

- The short-term prognosis for excessive daytime sleepiness and snoring is good to excellent with the regular use of CPAP, but no studies have been performed to address the long-term effects in a large population of patients.
- Residual symptoms of excessive daytime sleepiness can occur in some patients with OSA despite regular CPAP use. This has led the FDA to approve modafinil for the management of residual sleepiness.

REFERRAL

- Highly trained sleep specialists with expertise in caring for patients with OSA are recommended, especially for complex cases.
- Surgical referral to otolaryngology should be considered for children with adenotonsillar hypertrophy and for adults who are unresponsive to weight loss and CPAP therapy.
- Referral to a qualified dentist for treatment with an oral appliance may be useful for certain patients with mild OSA.

PEARLS & CONSIDERATIONS

- OSAH is a common disorder that is underrecognized and underdiagnosed, so the identification of risk factors is crucial for making the correct diagnosis.
- The prevalence of OSA increases among women after menopause.
- The single most effective therapy for OSA is CPAP administered by nasal or facial masks or other interfaces if required.
- Patients with OSA are more vulnerable than healthy persons to the effects of alcohol consumption and sleep restriction with regard to various driving performance variables.
- OSA is a risk factor for systemic and pulmonary HTN, stroke, atrial fibrillation, and coronary artery disease. In patients with untreated HTN and OSA, the use of CPAP results in small but statistically significant reductions in blood pressure. Therapy with CPAP has not been shown to prevent cardiovascular events in patients with moderate-to-severe obstructive sleep apnea and established cardiovascular disease.
- OSA may also be an independent risk factor for peptic ulcer bleeding.
- Ethnic differences may exist for some populations, with South Asians having a higher prevalence and risk for cardiovascular side effects.

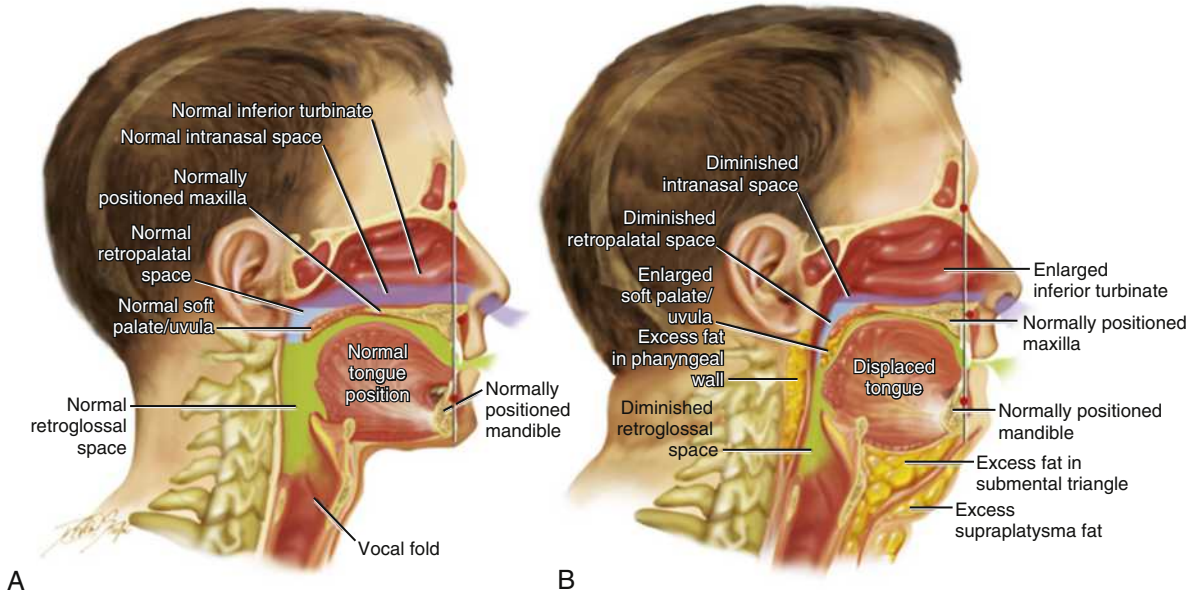

FIG. E1 Normal and abnormal airway anatomy. A, This illustrated midline sagittal cross section of the head and neck depicts the normal upper airway and maxillofacial spaces and anatomy of a healthy, normal-weight 20-yr-old man. The patient has a normal upper and lower facial skeleton and normal soft tissue indicators (soft palate, tongue, tonsils, and adenoids), without any compromise of the intranasal cavity. **B,** With increasing age and weight gain, the same individual, 3 decades later, has an elevated body mass index. Although the anatomy of the upper and lower facial skeleton remains fixed without any changes, fatty tissue consisting of adipose cells has expanded and infiltrated the crevices and space in the upper airway. Particularly compromised are the retropharyngeal and the lateral pharyngeal tissues, the soft palate, and the floor of the mouth, culminating in restricted airflow. At age 20 yr, the patient had normal upper airway space (the intranasal, retropalatal, and the retroglossal sites were all well visualized and with appropriate space for air flow to proceed smoothly and unimpeded). At age 50 yr, he has developed obstructive sleep apnea: The normal airspace *(green)* is severely compromised because of restriction of the upper airway, intranasal space, and retropalatal and the retroglossal spaces. A *perfect storm* indeed. (From Posnick JC: *Orthognathic surgery: principles and practice,* St Louis, 2014, Elsevier, 992-1058.)

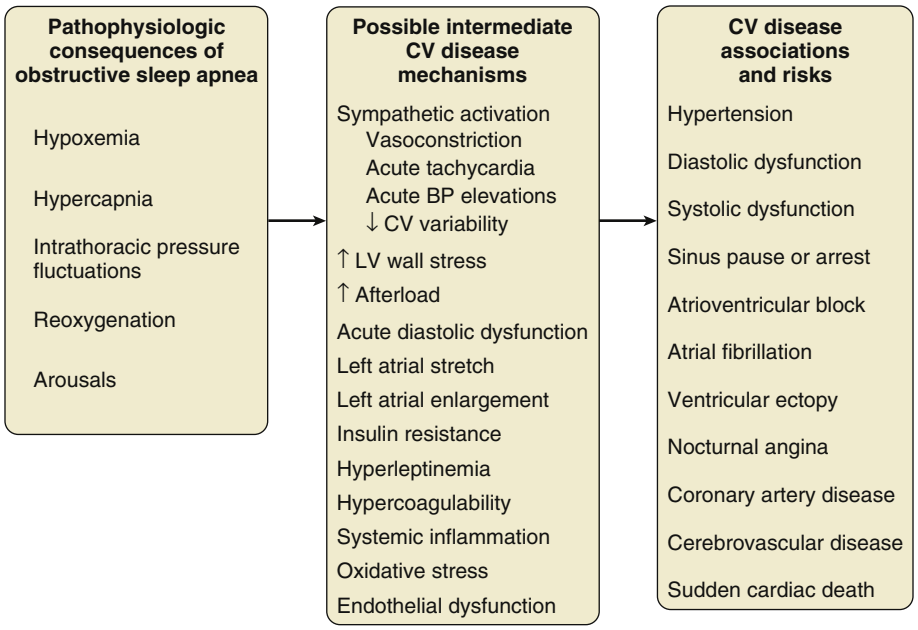

FIG. E2 The pathophysiologic consequences of obstructive sleep apnea disorders (OSA) may acutely and chronically elicit multiple intermediate cardiovascular *(CV)* disease mechanisms, which may promote the association of OSA with a number of cardiovascular conditions and diseases. *BP,* Blood pressure; *LV,* left ventricular. (From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.)

BASIC INFORMATION

DEFINITION

Slipped capital femoral epiphysis (SCFE) is characterized by displacement of the metaphysis (femoral neck) anteriorly on the capital femoral epiphysis (femoral head) at the level of the physis (growth plate). It commonly presents with hip or knee pain and an abnormal gait.

- Unilateral, but bilateral in about one fourth of cases. When bilateral or if age <10 yr old, may be associated with endocrinopathies.
- Classified as stable when the child is able to walk and bear weight, or unstable when the child is not.
- The child should remain non–weight-bearing pending orthopedic evaluation.

SYNONYMS

Slipped capital femoral epiphysis
SCFE

ICD-10CM CODES

M93.001	Unspecified slipped upper femoral epiphysis (nontraumatic), right hip
M93.002	Unspecified slipped upper femoral epiphysis (nontraumatic), left hip
M93.003	Unspecified slipped upper femoral epiphysis (nontraumatic), unspecified hip
M93.011	Acute slipped upper femoral epiphysis (nontraumatic), right hip
M93.012	Acute slipped upper femoral epiphysis (nontraumatic), left hip
M93.013	Acute slipped upper femoral epiphysis (nontraumatic), unspecified hip
M93.021	Chronic slipped upper femoral epiphysis (nontraumatic), right hip
M93.022	Chronic slipped upper femoral epiphysis (nontraumatic), left hip
M93.023	Chronic slipped upper femoral epiphysis (nontraumatic), unspecified hip
M93.031	Acute on chronic slipped upper femoral epiphysis (nontraumatic), right hip
M93.032	Acute on chronic slipped upper femoral epiphysis (nontraumatic), left hip
M93.033	Acute on chronic slipped upper femoral epiphysis (nontraumatic), unspecified hip

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence is 10 cases per 100,000, with a 1.4:2.0 female:male ratio. Left hip is more commonly affected than right hip.
PEAK INCIDENCE: Average age at diagnosis is 12 yr, with range of 10 to 16 yr.
PREVALENCE: 10.8 cases per 100,000 children
GENETICS: Greater incidence in blacks, Hispanics, and Pacific Islanders
RISK FACTORS:

- Obesity is by far the greatest risk factor
- Metabolic/endocrine disorder, radiation exposure
- Genetic

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presents with pain in the knee, hip, groin, or thigh and altered gait. Often presents with patient's refusal to bear weight.
- May note limited range of motion of the affected hip on internal rotation (Fig. E1), with obligatory external rotation if passively flexed up to 90 degrees.

ETIOLOGY

- Occurs when shearing forces at the femoral head exceed the strength of the capital femoral physis. Most commonly occurs during the preadolescent growth spurt.
- Multifactorial: Predisposing factors include obesity, trauma, history of radiation exposure, and endocrine/metabolic disorders.
- Obesity: 63% of affected patients are >90% for weight. Elevated leptin may be independently associated with increased odds of development of SCFE.
- Endocrine disorders: Consider an underlying endocrinopathy in patients who are <10 yr old or less than the fiftieth percentile for weight. Hypothyroidism, hypogonadism, panhypopituitarism, or growth hormone deficiency may be identified. Consider a screening of TSH/T_4 and bone age assessment at diagnosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Stress fracture or apophyseal avulsion fracture
- Avascular necrosis (Legg-Calvé-Perthes disease)
- Hip apophysitis
- Transient synovitis
- Septic arthritis or osteomyelitis
- Adductor muscle strain (groin pull)

WORKUP

- Diagnosis based on examination and radiologic findings.
- Laboratory testing can be done to look for secondary causes.

LABORATORY TESTS

Consider renal and endocrine (growth hormone and thyroid function) tests, especially in patients who are <10 yr or less than the fiftieth percentile for weight.

IMAGING STUDIES

- Obtain bilateral hip radiographs with both AP and frog-leg lateral views (Figs. E2 and E3), as about one fourth of cases are bilateral. Plain radiographs are both sensitive and specific enough to make the diagnosis.
- Widening, irregularity, and lucency of the physis may be noted, as well as incongruency of the proximal femoral epiphysis.
- The slip occurs at the weakest part of the physeal plate and results in the displacement of the head from the metaphysis, giving the characteristic "ice cream falling off the cone" appearance on radiographs.
- If the radiograph is normal but suspicion remains high, MRI may be diagnostic and is helpful in diagnosing complications of SCFE, such as osteonecrosis.

TREATMENT

- When suspicious for SCFE, place the child on non–weight-bearing crutches or in a wheelchair pending further evaluation.
- The initial goals of treatment are to prevent slip progression and avoid complications.
- Surgical management is required, and orthopedic referral is imperative. The gold standard procedure is insertion of a single or two cannulated screws at the center of the epiphysis. A second screw may be required to confer greater rotational stability but this carries higher risk of compromising the blood supply.

NONPHARMACOLOGIC THERAPY

- The standard treatment for SCFE is fixation with one or two cannulated screws.

f0010

FIG. E1 Clinical examination of a patient with a stable slipped capital femoral epiphysis. Hip flexion and external rotation are limited. With flexion of the affected hip, the limb rotates externally. (From Herring JA: Slipped capital femoral epiphysis. In Herring JA (ed): *Tachdjian's pediatric orthopaedics,* ed 5, Philadelphia, 2014, Elsevier, Fig. 18.5. In Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.)

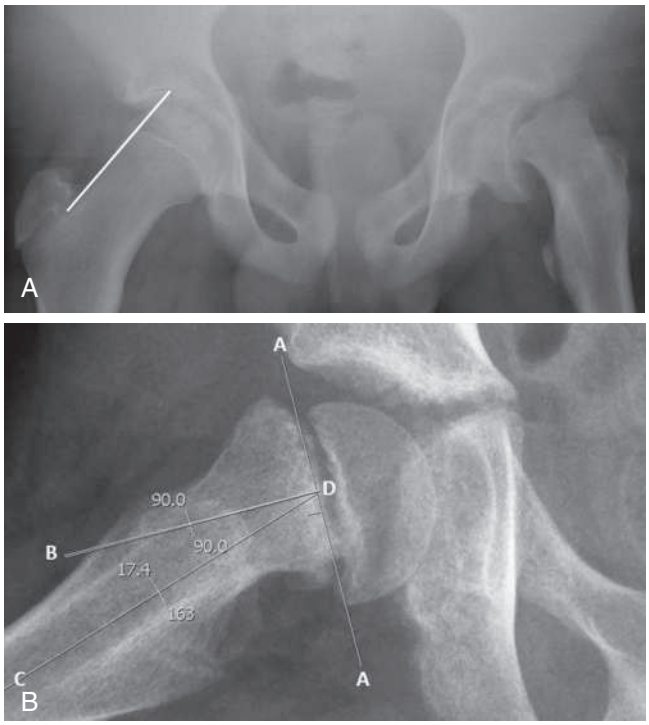

FIG. E2 Slipped capital femoral epiphysis. A, Left slipped capital femoral epiphysis. Klein's line is shown on the right. This line normally intersects approximately the lateral sixth of the capital femoral epiphysis in the AP projection. **B,** The slip angle—between (1) a line [BD] perpendicular to the plane of the growth plate [AA] and (2) a line [CD] parallel to the longitudinal axis of the femoral shaft in the frog lateral projection—is 17.4°. (From Adam A et al (ed): *Grainger and Allison's diagnostic radiology,* ed 6, London, 2015, Churchill Livingstone. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

FIG. E3 Slipped capital femoral epiphysis. Klein's line. (From Adam A, Dixon AK: *Grainger & Allison's diagnostic radiology,* ed 5, London, 2007, Churchill Livingstone. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

SUGGESTED READING

Castillo C, Mendez M: Slipped capital femoral epiphysis: a review for pediatricians, *Pediatr Ann* 47(9):e377-e380, 2018.

Georgiadis AD, Zaltz I: Slipped capital femoral epiphysis: how to evaluate with a review and update of treatment, *Pediatr Clin N Am* 61:1119-1135, 2014.

Otani T et al: Diagnosis and treatment of slipped capital femoral epiphysis: recent trends to note, *J Orthop Sci* 23(2):220-228, 2018.

Peck DM et al: Slipped capital femoral epiphysis: diagnosis and management, *Am Fam Phys* 95(12):779-784, 2017.

Zaltz I et al: Unstable SCFE: review of treatment modalities and prevalence of osteonecrosis, *Clin Orthop Relat Res* 471(7):2192-2198, 2013.

- Prophylactic treatment of the contralateral hip in SCFE is not recommended in most patients but can be considered for high-risk patients, such as those with endocrine disorders, young age, and obesity.

DISPOSITION

- SCFE is a common preadolescent disorder in which early diagnosis and proper management can prevent future complications such as osteonecrosis and chondrolysis.
- Chondrolysis: Acute dissolution of articular cartilage and narrowing of the joint space. The patient presents with pain, stiffness, and decreased range of motion. May be a complication of surgery but occurs in about 10% of cases of untreated SCFE.
- Osteonecrosis has a higher risk in unstable SCFE and is increased by the degree and angle of the slippage. Diagnose with MRI or bone scan.
- Recent studies have shown that postoperative AVN is prevented by monitoring physeal hemodynamics intraoperatively, including assessment of intracranial pressure by laser Doppler flowmetry and by confirmation of bleeding after drilling the femoral head.

PEARLS & CONSIDERATIONS

- Physicians should consider SCFE when a child between the ages of 10 to 15 yr presents with limping and groin, hip, thigh, or knee pain. One quarter of cases are bilateral, especially if there is underlying endocrinopathy.
- Endocrinopathy workup should be considered if age <10 yrs or less than fiftieth percentile by weight.
- Physical exam shows decreased internal rotation of the hip and obligatory external rotation.
- Radiography to evaluate for SCFE should include AP and frog-leg lateral views of the hips. Obtain cross table lateral views for unstable SCFE.
- Standard treatment of stable SCFE is in situ fixation with one or two cannulated screws.

Slipped Femoral Epiphysis (Patient Information)

AUTHOR: **Jacob Modest, MD**

BASIC INFORMATION

DEFINITION

Small bowel bacterial overgrowth (SIBO) is the presence of excessive native and/or nonnative bacteria in the small intestine (bacterial count $>10^5$/ml per jejunal aspirate) causing chronic diarrhea and malabsorption.

SYNONYMS

Bacterial overgrowth syndrome
SIBO

ICD-10CM CODES

K90.4 Malabsorption due to intolerance, NEC
K90.89 Other intestinal malabsorption

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The prevalence of SIBO is varied based on the population studied and the diagnostic tests used. It has shown to be prevalent in up to 12.5% to 20% of the healthy population using glucose and lactulose breath test.

PREDOMINANT SEX AND AGE: SIBO affects predominantly the elderly population or those with recent UGI surgery, including bariatric surgery. The elderly population has decreased gastric secretion and hypomotility due to age-associated decline as well as increased use of motility-altering medications.

RISK FACTORS:

- Advanced age is a known risk factor as there is thought to be an age-associated decline in GI motility.
- Patients with irritable bowel syndrome have a higher prevalence of SIBO compared to the general population. Initial studies have shown up to 65% to 80% of IBS patients with confirmed SIBO with an abnormal lactulose breath test.
- Other risk factors include UGI tract surgery, inflammatory bowel disease, chronic pancreatitis, immunodeficiency, liver disease, and obesity.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients will present with nonspecific findings, which include abdominal distention, bloating, and/or pain. Other common symptoms include diarrhea and subsequent weight loss and weakness. Pathophysiology of symptoms and clinical consequences of SIBO are summarized in Table 1.
- The severity of symptoms reflects the extent of bacterial overgrowth.
- Severe malabsorption can present as symptoms secondary to vitamin deficiencies. Fat-soluble vitamin deficiencies can present as night blindness (vitamin A), osteomalacia and hypocalcemia (vitamin D), or prolonged bleeding (vitamin K). Bacterial overgrowth can affect vitamin B_{12} absorption in the ileum leading to neuropathies with sensory ataxia.

ETIOLOGY

Disorders that disrupt protective mechanisms against bacterial burden predispose patients to SIBO. Box 1 summarizes diseases and disorders linked to SIBO based on pathophysiology.

- Patients with structural or anatomical abnormalities are at greater risk. These include patients with small bowel diverticula, small intestinal strictures, surgical blind loops, ileocecal resections, or gastric resections (increasing common cause of SIBO).
- Motility disorders predispose to SIBO because of the ineffective clearance of bacteria from the proximal bowel into the colon. Examples of this include gastroparesis and small bowel dysmotility, both suggestive of poorly controlled diabetes. Long-standing celiac disease can also interfere with small bowel motility.
- It is thought that recent antibiotic use as well as antacid medication can alter the normal bacterial flora in the small intestine, contributing to SIBO.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Celiac disease
- Chronic pancreatitis
- Inflammatory bowel disease
- Irritable bowel syndrome
- Tropical sprue
- Whipple disease
- Lactose intolerance

WORKUP

Diagnostic testing should include workup for diarrhea, anemia, and malabsorption. While endoscopy with jejunal aspirate and culture was a diagnostic tool of choice, its role is limited because of low specificity. While hydrogen breath tests have their limitations as well, they are noninvasive and easy to perform.

LABORATORY TESTS

- Breath tests have become more commonplace in diagnosing SIBO. Typically fermenting bacteria reside in the colon. In SIBO, fermenting bacteria is present in the small intestine as well. A carbohydrate test dose (typically lactulose or glucose) is given and its byproduct (hydrogen) is measured as it is excreted in the breath. In SIBO, exhaled hydrogen concentrations rise early.
- Standard anemia workup is essential. CBC may suggest macrocytic anemia secondary to B_{12} deficiency.
- Nutritional status should be evaluated with albumin levels.
- Stool evaluation can aid in the diagnosis as well. An increase in fecal fat may be suggestive of SIBO. Stool WBC, culture, ova, and parasites should be ordered as well to rule out other infectious etiology.

TABLE 1 Pathophysiology of Symptoms and Clinical Consequences in Small Bowel Bacterial Overgrowth

Process	Mechanisms of Action	Clinical Consequences
Mucosal injury induced by bacteria and/or their toxins or products	Loss of brush-border enzymes	Carbohydrate maldigestion
	Injury to epithelial barrier leading to enhanced intestinal permeability	Protein-losing enteropathy; bacterial translocation and portal and systemic endotoxemia
	Inflammatory response generating inflammatory cytokines	Liver injury and inflammation, systemic inflammatory responses
Luminal competition with the host for nutrients	Consumption of dietary protein	Hypoproteinemia, edema
	Consumption of vitamin B_{12}	B_{12} deficiency, megaloblastic anemia, neurologic symptoms
	Consumption of thiamine	Thiamine deficiency
	Consumption of nicotinamide	Nicotinamide deficiency
Bacterial metabolism	Fermentation of unabsorbed carbohydrates	Bloating, distension, flatulence
	Deconjugation of primary bile acids	Diarrhea due to the effects of deconjugated bile acids in the colon; depletion of the bile acid pool leading to fat and fat-soluble vitamin malabsorption
	Synthesis of vitamin K	Interference with dosing of vitamin K antagonists (e.g., warfarin)
	Synthesis of folate	High serum folate levels
	Synthesis of D-lactic acid	D-lactic acidosis
	Synthesis of alcohol	Liver injury
	Synthesis of acetaldehyde	Liver injury

From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

BOX 1 Diseases and Disorders Linked to Small Bowel Bacterial Overgrowth (SIBO) Based on Pathophysiology

Dysmotility
Acromegaly:
- Amyloidosis
- Chronic opiate use
- Diabetic autonomic neuropathy
- Gastroparesis
- Hypothyroidism
- Idiopathic intestinal pseudo-obstruction
- Long-standing use of motility-suppressing drugs
- Myotonic muscular dystrophy
- Systemic sclerosis/scleroderma

Altered Anatomy
Blind loops:
- Gastrocolic or jejunocolic fistula
- Ileocecal valve resection
- Small intestinal diverticulosis
- Strictures (Crohn disease, radiation, surgery)
- Surgically induced alterations in anatomy (Billroth II gastrectomy, end-to-side anastomosis)

Hypochlorhydria
Long-term acid suppression (?)
- Postsurgical

Immune Deficiency
Acquired immune deficiency (e.g., AIDS, severe malnutrition)
- Inherited immune deficiencies

Multifactorial Causes
Advanced age:
- Celiac disease
- Chronic pancreatitis
- Crohn disease
- Cystic fibrosis
- End-stage kidney disease
- Intestinal failure
- Liver disease
- Radiation enteropathy
- Tropical sprue

Unclear or Undefined Relationship to SIBO
Erosive esophagitis:
- Interstitial cystitis
- IBS
- Parkinson disease
- Restless legs syndrome
- Rosacea
- Severe obesity

From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

IMAGING STUDIES

- Endoscopic evaluation of the small intestine can be useful in finding structural and motility causes of bacterial overgrowth such as diverticula and strictures. Small bowel biopsy may aid in the diagnosis of celiac disease as well.
- Jejunal aspirate cultures via endoscopy are considered a standard of diagnosis. Aspirate cultures that exceed 10^5 organisms/ml suggest the presence of SIBO.
- There are several limitations to jejunal aspirate cultures. Bacterial overgrowth is not uniform and may be in inaccessible areas to endoscopist and can easily be missed. Contamination from oropharyngeal flora can lead to false-positive tests. Also endoscopy is an invasive test and other methods of testing such as a breath test may be a more practical initial approach.

Rx TREATMENT

The goal is to treat the underlying cause and treat the bacterial overgrowth with antibiotic therapy.

NONPHARMACOLOGIC THERAPY

Structural disorders such as strictures, fistula, and diverticula may require surgical intervention.

ACUTE GENERAL Rx

- 7- to 10-day course of antibiotic therapy with rifaximin, amoxicillin-clavulanate, or metronidazole and ciprofloxacin has been shown to be beneficial.
- Nutritional support with vitamin replacement and dietary modification (lactose-free diet).

CHRONIC Rx

- Recurrence is common after antibiotic therapy. These patients may require subsequent courses of antibiotic therapy.
- Avoid using antacid medication.
- Avoid drugs that reduce GI motility (opioids).
- Consider lactose-free diet if the response to antimicrobial agents is incomplete.

DISPOSITION

Prognosis is dependent on underlying cause of SIBO. Although recurrence rate is high, antibiotic therapy remains the mainstay of therapy often requiring repeated courses if the underlying condition cannot be resolved.

REFERRAL

- Gastroenterology consultation for small bowel evaluation
- Surgical consultation with an underlying structural disorder

PEARLS & CONSIDERATIONS

COMMENTS

- SIBO is due to a disruption of protective mechanisms against bacterial burden
- Look for risk factors including UGI tract surgery, structural disorders, IBD, IBS, and disorders decreasing GI motility.
- Diagnosis can be made with hydrogen breath test or endoscopic jejunal aspirate culture.
- Treatment is with antibiotics.
- The combination of vitamin B_{12} deficiency (due to bacterial consumption) and an elevated serum folate level (due to bacterial production) is suggestive of SIBO.
- SIBO can contribute to symptoms of IBS or IBD.

SUGGESTED READINGS

Bures J et al: Small intestinal bacterial overgrowth syndrome, *World J Gastroenterol* 16:2978-2990, 2010.

Quigley EM, Abu-Shanab A: Small intestinal bacterial overgrowth, *Infect Dis Clin North Am* 24:943-959, 2010.

BASIC INFORMATION

DEFINITION

- Small bowel obstruction can be **functional** (as a result of intrinsic abnormal intestinal pathology) or **mechanical** (which may occur acutely or may be chronic).
- Small bowel obstruction is due to intraluminal or extraluminal mechanical compression.
- Mechanical obstruction means the blockage of the intestinal lumen, preventing the passage of luminal contents through the gut tube. Adhesion disease is the most common cause of mechanical small bowel obstruction in developed countries.
- Mechanical obstruction may be either:
  1. **Simple obstruction:** In which the lumen may be *partially* or *completely blocked* but with intact intestinal blood flow *OR*
  2. **Strangulated obstruction:**
     a. This is a surgical emergency.
     b. Usually the obstruction is complete; blood flow to the obstructed segment is cut off; and tissue necrosis, gangrene, and perforation may occur.

ICD-10CM CODES

K56	Paralytic ileus and intestinal obstruction
K56.1	Intussusception
K56.2	Volvulus
K56.3	Gallstone ileus
K56.4	Other impaction of intestine
K56.5	Intestinal adhesions (bands) with obstruction
K56.6	Other and unspecified intestinal obstruction
K56.9	Ileus, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- The most frequently encountered surgical disorder of the small intestines is mechanical small bowel obstruction (SBO). This is a common surgical emergency.
- 75% of all cases of small bowel obstruction are due to intraabdominal adhesion related to prior abdominal surgery, such as appendectomy, colorectal surgery, and gynecologic procedures.

PREDOMINANT SEX AND AGE: None

RISK FACTORS

- Previous abdominal or pelvic surgery—most important risk factor for mechanical SBO in the U.S.
- Hernia (abdominal wall or groin)
- Prior abdominal irradiation
- Bowel neoplasm
- Foreign-body ingestion
- Parasitic infestation
- Gallstones
- Inflammatory/ischemic stricture

PHYSICAL FINDINGS & CLINICAL PRESENTATION

PHYSICAL FINDINGS: These may include:

- Dehydration (manifested by tachycardia, decreased urine output, orthostatic hypotension, dry mucous membrane)
- Abdominal distention may suggest an abnormal accumulation of air or fluid
- Hyperactive bowel sounds (an early occurrence)
- Tympany to abdominal percussion over a distended abdomen may indicate the presence of air
- Percussion dullness over a distended abdomen may indicate fluid
- High-pitched "tinkling" sound on auscultation of the abdomen
- Hypoactive bowel sounds (late finding)
- Hernia
- Rectal examination may reveal:
  1. Blood (suggestive of neoplasm or strangulation or mucosal ischemia)
  2. Masses (may suggest obturator hernia)
  3. Fecal impaction

CLINICAL PRESENTATION: There are four key symptoms: abdominal pain, vomiting, distention, p0185 and constipation.

- Abdominal pain (abrupt onset):
  1. Intermittent, crampy, or colicky
  2. Constant pain (that is, change in pain's character) signifies serious complication
- Abdominal distension: Indicates abnormal accumulation of air or fluid
- Nausea
- Vomiting (bilious vomiting seen in proximal obstructions)
- Diarrhea (early finding)
- Constipation (a late finding)
- Obstipation (inability to pass gas)

Hypotension, fever, tachycardia, leukocytosis, and peritoneal signs (these late findings may be seen with strangulation or intestinal ischemia) should compel urgency toward operative management

- It is important to perform serial abdominal examinations to detect changes early

ETIOLOGY

- Postoperative adhesions, especially prior abdominopelvic operations (may cause acute obstruction usually within 1 mo of surgery; or chronic obstructions can occur yrs later)
- Incarcerated inguinal hernia
- Malignant tumor
- IBD
- Gallstone ileus
- Stricture
- Cystic fibrosis
- Volvulus
- In children consider pyloric stenosis, intussusception, congenital atresia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Paralytic ileus
- Pseudo-obstruction
- Acute cholangitis
- Cholecystitis
- Gastroenteritis
- Inflammatory bowel disease
- Diverticulitis
- Endometriosis
- Mesenteric ischemia
- Pancreatitis
- Dysmenorrhea
- Ovarian torsion

WORKUP

During the initial evaluation of patients with suspected SBO, the primary objectives are to gauge the degree of metabolic derangement and volume depletion and to assess the need for and expediency of surgery. It is also important to exclude sepsis, perforation, and bowel ischemia. As with many surgical conditions, determining the correct diagnosis and management strategy hinges on a focused yet thorough history and physical examination.

LABORATORY TESTS

- Laboratory abnormalities are not diagnostic of bowel obstruction but instead may indicate complications of obstruction. Essential laboratory tests include:
  1. Basic metabolic panel (hyponatremia, hypokalemia)
  2. CBC: Hemoconcentration, leukocytosis
  3. Urinalysis
  4. Serum amylase: May be elevated
  5. LDH
  6. Hepatic panel
  7. Check serum lactate, blood cultures, ABG in patients with signs such as fever, hypotension, or change in mental status
  8. Type and cross-match (in anticipation of possible surgical intervention)

IMAGING STUDIES

- Image to confirm diagnosis, identify the location of the obstruction, and access the type of obstruction.
- Imaging also helps identify complications (perforation, necrosis, etc.) and possible cause of the obstruction.
- Initial radiographic evaluation begins with plain x-ray films of the abdomen (supine and upright) and an upright chest radiograph. An upright chest radiograph is of paramount importance to inspect for pneumoperitoneum and also for evidence of aspiration in a patient with a history of vomiting. A supine and upright plain abdominal x-ray in patients with suspected small bowel obstruction may show:
  1. Ladder-like pattern of dilated small bowel loops with air-fluid levels (Fig. 1) indicating small bowel obstruction
  2. Accumulation of air and fluid proximal and clearance of fluid and air distal to the post of obstruction
- Enteroclysis (a fluoroscopic x-ray of the small intestine) is useful in detecting obstruction and can distinguish partial from complete blockage and adhesions from metastases.
- CT scan is the study of choice if the patient has fever, tachycardia, abdominal pain, and leukocytosis. It can reveal the etiology of the obstruction: abscess, inflammatory process, extra-luminal pathology, and/or metastases.
- CT can elucidate the cause, such as the presence of a mass (Fig. 2) or a hernia with subsequent obstruction (Fig. 3). In addition, CT has high sensitivity for detecting strangulation and pneumoperitoneum indicative of a perforation and is particularly useful in the early postoperative setting to rule out ischemia, intraabdominal abscess, or morbidity as the underlying cause. It is also useful in patients with a history of

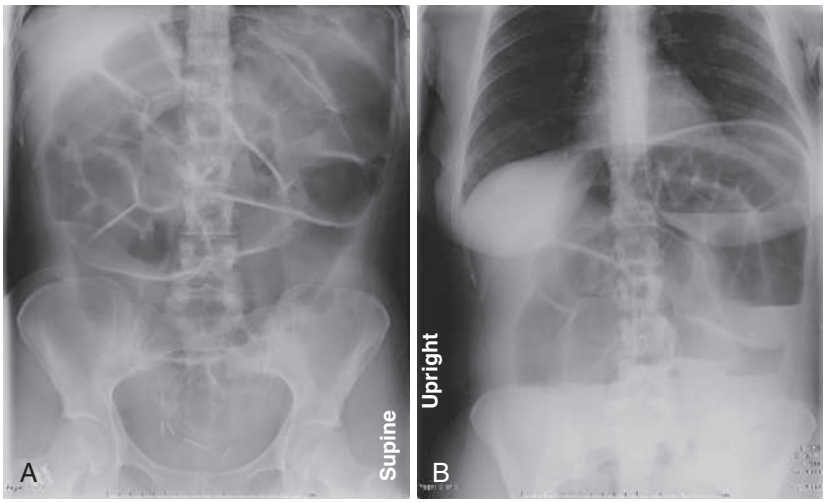

FIG. 1 A, Supine film showing dilated loops of small bowel in a patient with small bowel obstruction. **B,** Upright abdominal film revealing multiple air-fluid levels and small bowel dilation, consistent with a diagnosis of small bowel obstruction. (From Marx J: *Rosen's emergency medicine: concepts and clinical practice,* ed 6, Philadelphia, 2006, Saunders.)

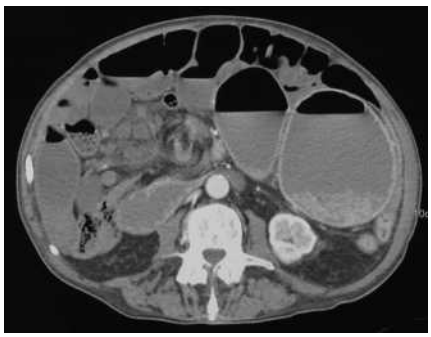

FIG. 2 Computed tomography scan of small bowel volvulus with notable mesenteric torsion. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.)

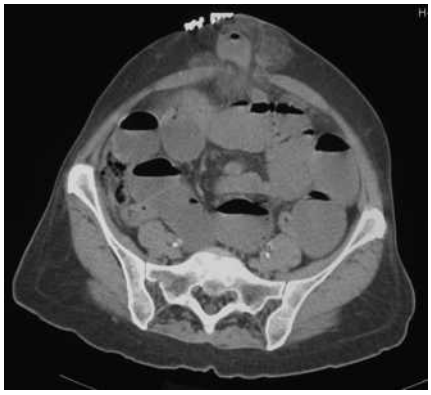

FIG. 3 Computed tomography scan of complete small bowel obstruction due to incisional hernia. (From Cameron IL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.)

malignancy to differentiate potentially recurrent disease from adhesions (Fig. 4).

- CT enterography, in which intraluminal distention is achieved with administration of large volumes of oral contrast such as water-methylcellulose solution, can be useful. This modality is most often used to diagnose patients with Crohn disease–related strictures, and its benefit is high-resolution imaging of the bowel wall; however, it is impractical in the patient with gastrointestinal (GI) distress who is nauseated and vomiting.

Rx TREATMENT

EMERGENCY ROOM CARE

- Vigorous fluid resuscitation and correction of electrolyte disorders underpin the initial therapeutic goals of both nonoperative and preoperative management strategies. Placing a Foley catheter to measure urinary output, establishing adequate intravenous access, and reassessing hemodynamic and electrolyte status are all essential in the initial management.

FIG. 4 Coronal image of computed tomography scan showing mass in proximal small bowel with decompressed loops of small bowel distal to obstruction. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.)

- Initial treatment consists of:
  1. Designate the patient nothing by mouth ("NPO")
  2. Fluid resuscitation (with isotonic Ringer or normal saline solution)
  3. Bowel decompression (via nasogastric [NG] tube placement): A standard NG tube provides symptomatic relief, prevents added gas and fluid accumulation proximally, and enables the serial assessment of antegrade fluid movement
  4. Correction of metabolic and electrolyte abnormalities
  5. Pain management
  6. Antiemetic administration
  7. Surgical consultation: Must be done early
  8. Antibiotic administration

NONSURGICAL INPATIENT CARE

General Principles:

- Bowel rest.
- Continue NG suction for decompression.
- Serial abdominal examination (q4 to 6h).
- Check labs, for example, CBC, BMP, lactic acid q6h.
- Provide adequate fluid.

Patients with low-grade partial SBOs are prone to spontaneous resolution with conservative interventions such as bowel rest, NG decompression, and appropriate fluid resuscitation. For partial or simple obstructions resolution usually occurs within 72 hr.

SURGICAL CARE

More than 25% of inpatients admitted because of SBO will require an operation. Patients with complete or high-grade partial SBO are most likely to need surgery, with less than 20% successfully managed nonoperatively. Surgery is indicated in:

- Strangulated obstruction (which is a surgical emergency)
- Patients with signs of necrosis or perforation (require prompt surgery)
- Simple complete obstruction: After failed nonoperative care

AUTHOR: **Daniel K. Asiedu, MD, PhD, FACP**

BASIC INFORMATION

DEFINITION

Smallpox infection is caused by the variola virus, a DNA virus member of the genus *Orthopoxvirus.* It is a human virus with no known nonhuman reservoir of disease. Natural infection occurs after implantation of the virus on the oropharyngeal or respiratory mucosa.

ICD-10CM CODES

B03	Smallpox
T50.B11A	Poisoning by smallpox vaccines, accidental (unintentional), initial encounter
T50.B11D	Poisoning by smallpox vaccines, accidental (unintentional), subsequent encounter
T50.B11S	Poisoning by smallpox vaccines, accidental (unintentional), sequela
T50.B12A	Poisoning by smallpox vaccines, intentional self-harm, initial encounter
T50.B12D	Poisoning by smallpox vaccines, intentional self-harm, subsequent encounter
T50.B12S	Poisoning by smallpox vaccines, intentional self-harm, sequela
T50.B13A	Poisoning by smallpox vaccines, assault, initial encounter
T50.B13D	Poisoning by smallpox vaccines, assault, subsequent encounter
T50.B13S	Poisoning by smallpox vaccines, assault, sequela
T50.B14A	Poisoning by smallpox vaccines, undetermined, initial encounter
T50.B14D	Poisoning by smallpox vaccines, undetermined, subsequent encounter
T50.B14S	Poisoning by smallpox vaccines, undetermined, sequela
T50.B15A	Adverse effect of smallpox vaccines, initial encounter
T50.B15D	Adverse effect of smallpox vaccines, subsequent encounter
T50.B15S	Adverse effect of smallpox vaccines, sequela
T50.B16A	Underdosing of smallpox vaccines, initial encounter
T50.B16D	Underdosing of smallpox vaccines, subsequent encounter
T50.B16S	Underdosing of smallpox vaccines, sequela
Z20.89	Contact with and (suspected) exposure to other communicable diseases

EPIDEMIOLOGY & DEMOGRAPHICS

- Smallpox infection was eliminated from the world in 1977. The last cases of smallpox, from laboratory exposure, occurred in 1978. The threat of bioterrorism has brought on renewed interest in the smallpox virus.
- Routine vaccination against smallpox ended in 1972.
- Smallpox is spread from person to person by infected saliva droplets in face-to-face contact with the ill person. Criteria for the suspicion of smallpox in patients with acute generalized vesicular or pustular rash are described in Box E1. Categorization of risk of smallpox from clinical criteria is described in Box E2.
- Persons with smallpox are most infectious during the first wk of illness, when the largest amount of virus is present in saliva; however, some risk of transmission lasts until all scabs have fallen off.
- The incubation period is approximately 12 days (range, 7 to 17 days) after exposure.
- Contaminated clothing or bed linens can also spread the virus. Special precautions need to be taken to ensure that all bedding and clothing of patients are cleaned appropriately with bleach and hot water. Disinfectants such as bleach and quaternary ammonia can be used for cleaning contaminated surfaces.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Initial symptoms include high fever, fatigue, and headaches and backaches. A characteristic rash, most prominent on the face, arms, and legs, follows in 2 to 3 days (Fig. E1).
- The rash starts with flat red lesions that evolve at the same rate. The rash follows a centrifugal pattern.
- Lesions are firm to the touch, domed, or umbilicated. They become pus filled and begin to crust early in the second wk.
- Scabs develop and then separate and fall off after approximately 3 to 4 wk. Depigmentation persists at the base of the skin lesions for 3 to 6 mo after illness. Scarring is usually most extensive on the face.
- Associated with the rash may be fever, headache, generalized malaise, vomiting, and colicky abdominal pain.
- Variola major may produce a rapidly fatal toxemia in some patients.
- Complications of smallpox include dehydration, pneumonia, blepharitis, conjunctivitis, and corneal ulcerations.

ETIOLOGY

Smallpox is caused by the variola virus. There are at least two strains of the virus, the most virulent known as *variola major* and a less virulent strain known as *variola minor* (alastrim).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rash from other viral illnesses (e.g., hemorrhagic chickenpox, measles, Coxsackievirus). Table E1 summarizes distinguishing features of smallpox and varicella
- Abdominal pain may mimic appendicitis
- Meningococcemia
- Insect bites
- Impetigo
- Dermatitis herpetiformis
- Pemphigus
- Papular urticaria

WORKUP & LABORATORY TESTS

- Laboratory examination requires high-containment (BL-4) facilities.

BOX E1 Criteria for Suspicion of Smallpox in Patients with Acute Generalized Vesicular or Pustular Rash

- Febrile prodrome:
  1. >101° F (>38.3° C), 1-4 days before rash onset
  2. With headache, backache, or abdominal pain
- Firm, deep-seated, well-circumscribed vesicles/pustules
- Lesions in the same stage of development in any one area of the body

Minor Smallpox Criteria

- Centrifugal distribution
- First lesions in the pharynx, oral mucosa
- Patient appears "toxic"
- Slow evolution of the rash:
  1. 1-2 days each stage: Macule, papule, vesicle
- Lesions on palms and soles

From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.

BOX E2 Categorization of Risk of Smallpox from Clinical Criteria

High Risk of Smallpox

- Febrile prodrome *and*
- Classic smallpox lesion *and*
- Lesions in the same stage of development

Moderate Risk of Smallpox

- Febrile prodrome *and* one other *major* smallpox criterion *or*
- Febrile prodrome *and* four or more minor smallpox criteria

Low Risk of Smallpox

- No febrile prodrome or
- Febrile prodrome *and* fewer than four minor smallpox criteria

From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.

FIG. E1 Smallpox. Multiple, tense pustules of the face in a patient from Ghana with smallpox. (Courtesy Centers for Disease Control and Prevention, Dr. J. Noble Jr. From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

TABLE E1 Distinguishing Features of Smallpox and Varicella

	Smallpox	Varicella
Prodrome	High fever, headache, backache, malaise	Mild fever, constitutional symptoms
Skin examination	Centrifugal distribution; pustules all in same stage of development; deep involvement	Central distribution; vesicles and crusted papules in different stages at one time; superficial
Scarring	Common; often severe	Occasional; usually mild (unless secondary bacterial infection)
Complications	Bacterial infection, pneumonia, arthritis, encephalitis, blindness, death	Bacterial infection; rarely pneumonia, encephalitis, arthritis

From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.

- Electron microscopy of vesicular scrapings can be used to distinguish poxvirus particles from varicella-zoster virus or herpes simplex. To obtain vesicular or pustular fluid it may be necessary to open lesions with the blunt edge of a scalpel. A cotton swab may be used to collect the fluid.
- In the absence of electron microscopy, light microscopy can be used to visualize variola viral particles (Guarnieri bodies) after Giemsa staining.
- Polymerase chain reaction techniques and restriction fragment-length polymorphisms can rapidly identify variola.

IMAGING STUDIES

Chest radiograph in patients with suspected pneumonia

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive therapy
- IV hydration in severe cases
- A suspected case of smallpox should be placed in strict respiratory and contact isolation

ACUTE GENERAL Rx

- There is no proven treatment for smallpox. Vaccination administered within 3 to 4 days may prevent or significantly ameliorate subsequent illness. Vaccinia immune globulin can be used for treatment of vaccine complications and for administration with vaccine to those for whom vaccine is otherwise contraindicated.
- Patients can benefit from supportive therapy (e.g., IV fluids, acetaminophen for pain or fever).
- Antibiotics are indicated only if secondary bacterial infections occur. Penicillinase-resistant antimicrobial agents should be used if smallpox lesions are secondarily infected.
- Topical idoxuridine should be considered for corneal lesions.

DISPOSITION

- The mortality rate for variola major is 20% to 50%. Variola minor has a mortality rate of 1%.
- After severe smallpox, pitted lesions (most commonly on the face) are seen in up to 80% of survivors.
- Panophthalmitis and blindness from viral keratitis or secondary eye infection occur in 1% of patients.
- Arthritis caused by viral infection of the metaphysis of growing bones occurs in 2% of children.

REFERRAL

ID consultation and notification of local health authorities is mandatory in all cases of smallpox.

PEARLS & CONSIDERATIONS

- The smallpox virus is fragile; in the event of an aerosol release, all viruses will be inactivated or dissipated within 1 to 2 days. Buildings exposed to the initial aerosol release of the virus do not need to be decontaminated. By the time the first cases are identified, typically 2 wk after release, the virus in the building will be gone. Infected patients, however, will be capable of spreading the virus and possibly contaminating surfaces while they are sick. Standard hospital-grade disinfectants such as quaternary ammonias are effective in killing the virus on surfaces and should be used for disinfecting hospitalized patients' rooms or other contaminated surfaces. In the hospital setting, patients' linens should be autoclaved or washed in hot water with bleach added. Infectious waste should be placed in biohazard bags and autoclaved before incineration.
- Symptomatic patients with suspected or confirmed smallpox are capable of spreading the virus. Patients should be placed in medical isolation to avoid spread of the virus. In addition, people who have come into close contact with smallpox patients should be vaccinated immediately and closely watched for symptoms of smallpox.
- Traditional smallpox vaccines are based on replicating vaccinia viruses and have considerable side effects. Recent phase 3 trials of modified vaccinia Ankara (MVA) as a vaccine against smallpox did not identify any safety concerns. Immune responses and attenuation of the major cutaneous reaction suggest that this MVA vaccine protected against variola infection.[1]

COMMENTS

- In people exposed to smallpox, the vaccine can lessen the severity of or even prevent illness if given within 4 days of exposure.
- The vaccine against smallpox contains another live virus called *vaccinia.* The vaccine does not contain smallpox virus. Smallpox vaccination produces a skin lesion that is infectious. Vaccine virus in the skin lesion can be transferred to others if the skin lesion is touched directly or if the bandage is handled casually with ungloved hands. The vaccination site is infectious until the scab falls off, approximately 21 days after vaccination.
- Primary vaccination confers full immunity to smallpox in more than 95% of persons for up to 10 yr.

BASIC INFORMATION

DEFINITION

Social anxiety disorder (SAD) is a persistent and intense fear of being embarrassed, humiliated, or negatively evaluated in social situations. SAD commonly presents as excessive anxiety or fear in situations involving social interactions (e.g., conversing with one or a group of other individuals, with sexually attractive others, with authority figures), performance situations (e.g., public speaking, acting/performing in front of an audience), or situations in which one is being observed (e.g., while eating). Individuals with SAD fear that they will behave in these situations in ways that will cause them to be embarrassed or that others will judge them negatively. Many individuals also fear that they will show anxiety symptoms that will be observed by others. The anxiety must persist in these situations for at least 6 mo, and for children it must occur with peers and not just with adults. The anxiety often results in avoidance of these situations, thus leading to significant occupational, academic, and/or social impairment as well as marked distress. A specifier of "performance only" should be given when the fears are confined to speaking or performing in public.

SYNONYMS

Social phobia
SAD

ICD-10CM CODES

F93.2	Social anxiety disorder of childhood
F40.1	Social phobias
F40.9	Phobic anxiety disorder, unspecified

DSM-5

300.23	Social phobia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Ranges from 4 to 5 to 9/1000 person-yr; cumulative incidence of 11.0% in first 3 decades of life

PEAK INCIDENCE: Highest standardized incidence rates per person-yr between 10 and 19 yr of age

PREVALENCE (IN U.S.): Lifetime prevalence of 12% in epidemiologic samples, and 12-mo prevalence of 7%; point prevalence of up to 30% in outpatient clinical settings

PREDOMINANT SEX: More common in women than in men (odds ratio of 1.5 to 2.2) in epidemiologic samples, but men are more likely to seek treatment

PREDOMINANT AGE: Mean age at onset ~16 yr of age; median age at onset, 13 yr of age; onset rarely occurs after age 25, with 75% having an onset between 8 and 15 yr of age

GENETICS:

- Heritability ranges from 20% to 50%.
- 15% to 26% risk of SAD among first-degree relatives of those with SAD.
- There have been no consistent findings to demonstrate specific genes associated with SAD.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical symptoms during social interactions such as heart palpitations, sweating, shaking, and/or blushing, which may take the form of a panic attack.
- Fear that others will observe these physical symptoms in social situations and negatively judge them; fears that they will "say something stupid," make a mistake, or offend others also are common.
- Report being "shy" most of their lives.
- Comorbid psychiatric disorders (e.g., major depression, other anxiety disorders) and substance abuse (e.g., alcohol/cannabis) are common.
- Common sociodemographic features include younger age, female gender, unmarried status, lower education, and lower income.
- Few seek treatment specifically for SAD, and instead initially seek treatment for other psychiatric disorders (e.g., major depression, other anxiety disorders).
- The onset of SAD often precedes that of the other comorbid psychiatric conditions.

ETIOLOGY

- There is no clear etiology and likely is a combination of multiple factors.
- Research has examined developmental psychology factors (e.g., lack of modeling of socialization by parents), temperamental factors (e.g., behavioral inhibition), and occurrence of prior traumatic social experiences (e.g., significant teasing by peers, being embarrassed or humiliated in a social or performance situation).
- The risk of SAD also may be increased with family history.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other anxiety disorders (e.g., panic disorder with agoraphobia)
- As a consequence of mood disorders (e.g., avoidance of social situations associated with major depression)
- Pervasive developmental disorder (e.g., autism spectrum disorder)
- Personality disorders (e.g., schizoid personality disorder); however, in the case of avoidant personality disorder, both may be diagnosed
- Anxiety associated with medical conditions such as stuttering or Parkinson disease

WORKUP

- Psychiatric history is required for a diagnosis.
- Screening measures may improve detection of SAD as it is a chronic, disabling condition for which many individuals do not seek treatment.
- Physical examination may be useful in ruling out other explanations for physical symptoms that are present, and to rule out presence of social anxiety due to a medical condition.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cognitive-behavior therapy (CBT)
- Acceptance and Commitment Therapy (ACT)
- Interpersonal Psychotherapy (IPT)
- Exposure therapy
- Social skills training

PHARMACOLOGIC THERAPY

- SSRIs/SNRIs
- Benzodiazepines (less favored)
- MAOIs (less favored)
- Beta-blockers (e.g., propranolol, atenolol—for performance-related anxiety)

ACUTE GENERAL Rx

- SAD is a chronic condition; therefore acute treatment is rarely indicated.
- However, benzodiazepines or beta-blockers may be prescribed on an as-needed basis for acute performance anxiety. Caution should be taken when prescribing benzodiazepines due to the possibility of dependence or misuse and high incidence of relapse following discontinuation, and long-term use of these medications generally is discouraged.
- Beta-blockers may also be prescribed on an as-needed basis, particularly for physical symptoms experienced during performance situations. However, evidence does not support their use for more generalized forms of SAD.

CHRONIC Rx

- CBT is effective and an appropriate first-line treatment.
- SSRIs/SNRIs (e.g., sertraline, escitalopram, paroxetine, venlafaxine) are also effective in the treatment of SAD and are a first-line pharmacologic treatment.
- MAOIs previously were considered gold-standard treatment for SAD, but currently are less favorable due to side effects and dietary restrictions.
- Combination treatment of SSRI/SNRI and CBT is effective for SAD; ensuring CBT as an intervention may result in greater long-term benefit.

DISPOSITION

- SAD is a chronic condition, typically unremitting without treatment.
- Treatment may significantly improve SAD, although symptoms and impairment may continue to be present for some individuals following treatment.

REFERRAL

- If comorbid psychiatric conditions are present
- If the symptoms do not improve upon treatment or response to treatment is not optimal

BASIC INFORMATION

DEFINITION

Somatic cough syndrome, formerly psychogenic cough, is a disorder of chronic, debilitating cough that is medically unexplained despite extensive medical evaluation. It is a diagnosis of exclusion. The cough is considered to have a psychologic or psychiatric etiology and is not intentionally produced or feigned.

SYNONYMS

Psychogenic cough
Tic cough
Habit cough
Functional cough
Involuntary cough syndrome
Psychogenic cough tic
Psychosomatic cough

ICD-10CM CODES

F45.8	Other somatoform disorders (NOTE: ICD-10 uses DSM-IV terminology)
F45.1	Undifferentiated somatoform disorder
F95.9	Tic disorder, unspecified (referring to tic cough)
F95.1	Chronic vocal tic disorder (referring to tic cough)

DSM-5 CODES

300.82	Somatic symptom disorder
307.20	Other specified tic disorder (tic cough)
307.22	Chronic motor or vocal tic disorder

EPIDEMIOLOGY & DEMOGRAPHICS

There is a paucity of data on somatic cough syndrome. The evidence that exists is of limited quality due to the lack of control groups, the retrospective nature of all the studies, varying definitions and terminology, and evolving diagnostic criteria. For example, the most recent American College of Chest Physicians (ACCP) guidelines published in 2015 recommended replacing the terms "psychogenic cough" and "habit cough" with "somatic cough syndrome" and "tic cough," to align with the *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (*DSM-5*), classification of diseases. However, these recommendations have not been readily adopted in research or in practice based on the subsequent literature.

INCIDENCE: Unknown

PEAK INCIDENCE: Somatic cough disorder incidence peaks at age 8 to 14 yr.

PREVALENCE: Unknown

PREDOMINANT SEX AND AGE: There is no gender difference in children. In adults, there may be a female predominance, although limited data exist. Somatic cough syndrome is more common in children, adolescents, and young adults and is one of the most common causes of chronic cough in 6- to 16-yr-olds. Somatic cough syndrome is thought to be uncommon in adults, although it may be underreported or underdiagnosed.

GENETICS: None known

RISK FACTORS

- There are no systematic studies identifying risk factors for somatic cough syndrome.
- Because the 2015 ACCP guidelines recommend that for a diagnosis of somatic cough syndrome the patient must meet criteria for somatic symptom disorder (see later), the risk factors should be similar. These include a complex interplay of:
  1. Predisposing factors: Early adverse life events
  2. Precipitating factors: Recent illness, problems at work/school, and psychiatric illness
  3. Perpetuating factors: Poor health, chronic stress, isolation, sick role/illness behavior, and misdiagnosis/mistreatment
- In population studies of individuals with chronic cough, anxiety and depression were increased in some but not all individuals.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Although there are no distinguishing clinical features that reliably differentiate somatic cough syndrome from other causes of chronic cough, certain characteristics are considered supportive of the diagnosis (see Table E1). These include:

- A loud, dry, honking cough, absent during sleep, and prominent during clinic visits.
- The cough often begins at the time of an upper respiratory infection, fails to resolve, and may lead to excessive work/school absences.
- There is no consistent response to antitussive medication, bronchodilators, steroids, or antibiotics.
- Cough duration is highly variable, lasting from several wk to decades.
- In children, the cough is often much more bothersome to parents/other adults than to the patient and rarely affects play, speech, or eating.
- The cough is not intentionally produced or feigned.
- In both children and adults with unexplained chronic cough despite extensive medical evaluation, the presence of the core clinical features of tics, including suppressibility, distractibility, suggestibility, variability, and the presence of a premonitory sensation whether the cough is single or one of many tics is supportive of the diagnosis of tic cough. However, the distinction between somatic cough syndrome and tic cough is not entirely clear.
- Cases of Tourette syndrome presenting with unexplained chronic cough have been reported, and an evaluation for a tic disorder should be considered if other suggestive signs are present.

ETIOLOGY

- The exact cause of somatic cough syndrome is not clear. Various factors may play a role, including:
  1. Genetic and biological factors, for example, resulting in a vulnerability trait
  2. Family influence, which may be genetic or environmental, or both
  3. Decreased awareness of or difficulty processing emotions, causing the patient to shift the focus to physical symptoms rather than emotional or psychological issues
  4. Learned behavior—for example, the attention or other benefits gained from having an illness, which is often not recognized at a conscious level

TABLE E1 Clinical Features Suggestive of Somatic Cough Syndrome

Prominent during clinic visits
Often, but not always, absent during sleep
Rarely interrupts play, speech, or eating in children
May have a barking or honking quality after short inhalation, though this is not diagnostic
May lead to excessive absences from school or work
Often begins at the time of an upper respiratory tract infection and fails to resolve
No consistent response to antitussive medication, bronchodilators, steroids, or antibiotics

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

In children:

- Medical: Cough-dominant asthma, airway malacia, postviral cough, increased cough receptor sensitivity, foreign body ingestion, otogenic cough, protracted bacterial bronchitis
- Psychiatric: Tourette syndrome

In adults:

- Medical: Asthma, gastroesophageal reflux disease, medication-associated (ACE inhibitors), lung cancer, chronic bronchitis

WORKUP

- A comprehensive medical evaluation should be undertaken for common and uncommon causes of chronic cough. Chronic cough management algorithms are helpful to guide evaluation.
- Clinical interview should query for a history of psychiatric illness, history of substance abuse, recent and past psychosocial stressors, adverse early life experiences, and preceding medical (specifically respiratory) illness, along with previous pharmacologic and nonpharmacologic treatment trials. The impact of symptoms on work/school should also be assessed.
- Laboratory, imaging, and other diagnostic studies, such as chest x-ray and pulmonary function testing, should be undertaken if indicated by history or physical examination.

- 2015 ACCP guidelines on somatic cough syndrome recommend against anchoring a somatic cough syndrome diagnosis on the presence or absence of nighttime cough or cough with a barking or honking quality.
- A recently described "cough monitoring method" may be helpful in objectively identifying variation in cough characteristics during daytime compared to during sleep, based on the rationale that nighttime cough in somatic cough syndrome is significantly different from daytime cough. The method involves measuring cough sounds and thoracoabdominal movement with specialized equipment; however, more research is needed to validate this novel technique.
- The patient should meet *DSM-5* criteria for somatic symptom disorder, which include:
  1. One or more somatic symptoms that result in disruption of daily life.
  2. Excessive thoughts, feelings, and behaviors related to these somatic symptoms or associated health concerns. At least two of the following are needed to meet this criterion:
     a. High level of health-related anxiety
     b. Disproportionate and persistent concerns about the medical seriousness of one's symptoms
     c. Excessive time and energy devoted to these symptoms or health concerns
  3. The symptom lasts >6 mo.
- An isolated cough tic lasting greater than 1 yr would be considered chronic vocal tic disorder by *DSM-5* criteria.

Rx TREATMENT

- The mainstay of treatment for somatic cough syndrome involves nonpharmacologic approaches. Guidance on treatment is limited by the lack of controlled studies. Many interventions, including pharmacotherapy, behavioral modifications, and psychotherapy, have been used. There is no evidence that pharmacologic approaches are effective.
- In general, studies reported lack of benefit of pharmacologic interventions (antibiotics, cough suppressants, antihistamines, bronchodilators, and steroids).
- In contrast to a common view in individuals with chronic cough, that the cough is a reflex and involuntary, functional MRI studies demonstrate the role of the supramedullary pathways, including the cerebral cortex during cough, and changes in brain behavior during active cough suppression, suggesting a voluntary component to cough.
- Behavioral treatments where patients are taught to identify precipitating sensations to the cough are designed to help the patient "take control" of the cough and take an active role in their treatment.
- Hypnosis, suggestion therapy (see Table E2), reassurance, and counseling, along with appropriate psychotropic medication for psychiatric comorbidities, have been shown to be effective.
- Referral to psychologist or psychiatrist may be appropriate.
- In a systematic review of "psychogenic cough" treatment studies, which included 18 uncontrolled studies, Haydour et al. found that hypnosis (three studies), suggestion therapy (four studies), and counseling and reassurance (seven studies) were the most commonly used interventions.
  1. Hypnosis was effective in resolving cough in 78% of the patients and improving it in another 5%.
  2. Suggestion therapy resolved cough in 96% of patients.
  3. Pediatric patients had the most benefit from these forms of therapy.
- Vocal-fold injection of botulinum toxin type A was reported in three pediatric cases of debilitating chronic cough and was effective in disrupting the cough cycle. However, the cough recurred from 10 days to 2.5 mo later, and behavioral therapy was subsequently successful in controlling the cough.
- Patient values, preferences, and availability of potential therapies should guide treatment choice.

COMPLEMENTARY & ALTERNATIVE MEDICINE

None known

DISPOSITION

- Somatic cough syndrome has a good prognosis if diagnosed and treated early and often resolves with behavioral therapies (see earlier).
- Delay in diagnosis, misdiagnosis, and mistreatment can exacerbate the numerous physical, social, and emotional side effects of chronic cough, such as avoidance of daily activities, difficulty with interpersonal relationships, stress urinary incontinence, and avoidance of talking.
- It is therefore important to include somatic cough syndrome in the differential diagnosis of persistent or recurrent chronic cough and asthma that is difficult to control and refractory to standard pharmacologic approaches.

REFERRAL

Referral to psychologist and/or psychiatrist should be considered if diagnosis is complicated by difficult-to-treat comorbid psychiatric conditions.

PEARLS & CONSIDERATIONS

COMMENTS

- Consider that there may be more than one cause of a chronic cough.
- Newer concepts, including idiopathic cough, unexplained cough, cough hypersensitivity syndrome, and laryngeal hypersensitivity, are also used to describe medically unexplained cough. Further research is needed to better elucidate these entities and how they diverge from somatic cough syndrome.

PREVENTION

There are no known preventive measures.

SUGGESTED READINGS

Available at ExpertConsult.com

TABLE E2 Steps to Suggestion Therapy in Somatic Cough Syndrome

1. Explain to the patient that the irritant that originally caused the cough is now gone, and their current cough is contributing to an ongoing cycle of more irritation and more coughing.
2. Advise the patient that each second the cough is delayed will make the cough easier to suppress.
3. Instruct the patient to focus all of their attention on suppressing the urge to cough for 1 min. After this is accomplished, progressively increase the amount of time while concurrently offering an alternative behavioral strategy to reduce irritation, such as sipping lukewarm water or inhaling a cool mist from a vaporizer.
4. As the patient demonstrates the ability to voluntarily resist coughing for increasing time periods, continue to confidently acknowledge this success.
5. When the patient is able to suppress the urge to cough for about a 10-min interval, inquire, "you're beginning to feel you can resist the urge to cough, aren't you?"
6. When the patient is able to consistently answer affirmatively to the question, "Do you feel that you can now resist the urge to cough on your own?" then the session can be ended. Note: Only ask this question after the patient has suppressed the cough for at least 5 min.
7. Finally, express confidence and encouragement that the patient can resist the urge to cough at home (autosuggestion).

Somatic Symptom Disorder

BASIC INFORMATION

DEFINITION

Somatic symptom disorder is a new diagnostic entity subsumed within *DSM-5* under somatic symptom and related disorders. It replaces somatization disorder. Patients with these disorders are usually encountered in primary medical settings, and thus the diagnoses have been reconceptualized to make them more useful for nonpsychiatric providers. Previous criteria overemphasized the concept of the medically unexplained symptom, which has now been dropped in favor of incorporating affective, cognitive, and behavioral components to more accurately reflect the clinical picture. In this particular condition, patients often present with one or more somatic symptoms that are perceived as distressing, which significantly disrupt daily life. They interpret or understand bodily symptoms as harmful and threatening. It is crucial to understand that somatic symptoms without a medical explanation are not sufficient to make the diagnosis. *DSM-5* somatic symptom disorder (SSD) with predominant pain replaces *DSM-IV-TR* pain disorder. The differential diagnosis of SSD includes related conditions that are in the same *DSM-5* category: illness anxiety disorder; conversion disorder, factitious disorder, and other specified somatic symptom and related disorders such as pseudocyesis (a false belief of being pregnant with associated signs and reported symptoms).

SYNONYMS

Functional syndrome
Nonorganic symptoms
Medically unexplained symptoms
Somatization syndrome
Somatoform disorder

ICD-10CM CODE	
F45.1	Somatoform disorder
ICD-10CM CODE	
300.82	Somatic symptom disorder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Not known
PEAK INCIDENCE: Not known
PREVALENCE: Estimated to be around 5% to 7%
PREDOMINANT SEX AND AGE: Females tend to report more somatic symptoms.
GENETICS: Not known, but thought to contribute along with other factors
RISK FACTORS: Tendency to experience negative affect (neuroticism), limited education, lower socioeconomic status, recent stressful life events, childhood adversity, or abuse

PHYSICAL FINDINGS & CLINICAL PRESENTATION

These patients usually present with multiple somatic symptoms that are distressing and disrupt life and function. Symptoms can be specific, such as localized pain, but often are not. These somatic symptoms can coexist with another medically diagnosable condition. They present with high levels of anxiety about their symptoms, which they focus on excessively and perceive as unduly threatening. They have a high level of utilization of medical services.

ETIOLOGY

Thought to be the result of multiple contributing factors such as genetic predisposition, early traumatic experiences, learning, cultural, and social issues

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other medical conditions: Symptoms of unknown etiology are insufficient to make the diagnosis of somatic symptom disorder. Multisystemic disorders (e.g., autoimmune disorders), pheochromocytoma, and carcinoid and endocrinopathies may present with multiple somatic complaints and psychological symptoms.
- Illness anxiety disorder: Distress about the meaning of the complaint, not the symptom itself.
- Conversion disorder: Voluntary motor or sensory symptom not compatible with known neurological condition.
- Factitious disorder: Falsification of physical or psychological symptoms or induction of injury/disease.
- Mood and anxiety disorders.
- Obsessive-compulsive disorder: Intrusive thoughts, images about the symptoms.
- Delusional disorder: If beliefs about somatic symptoms are rigid and firmly held.
- Malingering.

WORKUP

Rule out general medical conditions. With patients suspected or known to experience recurrent somatic symptoms, a conservative approach that limits the use of tests is best, as testing may only serve to reinforce the underlying beliefs about the nature of the symptoms.

LABORATORY TESTS

No specific laboratory test is required, except as indicated by history and physical examination.

IMAGING STUDIES

No specific imaging test is required, except as indicated by history and physical examination.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Establish a therapeutic alliance with the patient.
- Validate concerns and suffering.
- Elicit expectations and help set goals that are realistic.
- Preliminary studies using cognitive behavioral therapy or acceptance and commitment therapy or mindfulness-based stress reduction show feasibility and early promise.

ACUTE GENERAL Rx

- Brief examination that focuses on complaint area.
- Explore current psychosocial issues.
- Provide empathy and support.
- Benefit from antidepressant medication for somatic symptoms is unclear, but this benefit may be independent of depression.
- Serotonergic and noradrenergic transmission mediates endogenous analgesic mechanisms via descending inhibitory pathways in the central nervous system and may play a role in the heightened pain sensitivity seen in many of these patients.

CHRONIC Rx

- Single provider to manage overall care.
- Safeguard against patient's doctor-shopping tendency when possible.
- Provide empathy and support while reinforcing previously set goals, particularly restoration of function.
- Regular follow-up to support therapeutic relationship.
- Avoid invasive or extensive testing unless clinically warranted.
- Treat coexisting mood and anxiety disorders.

DISPOSITION

This is a chronic condition with frequent exacerbations requiring close follow-up.

REFERRAL

To a psychiatrist and/or a psychotherapist if patient is psychologically minded and open to referral

PEARLS & CONSIDERATIONS

- Some mental disorders may initially manifest with somatic symptoms; with multiple somatic symptoms, there is a higher likelihood of psychopathology.
- It is important to elicit the patient's own explanatory models for his or her symptoms.
- When more psychological explanations are reported, the patient is more likely to be disabled.
- Some patients have a negative self-perception that can persist and is a strong predictor of poor outcome.
- Patients may have catastrophic thinking and may be hostile to previous doctors, whom they may blame.
- Help patients reframe thoughts and keep focus on restoring function rather than on diagnosis and elimination of symptoms.

Southern Tick-Associated Rash Illness (STARI)

BASIC INFORMATION

DEFINITION

A rash, similar to the erythema migrans (EM) rash of Lyme disease, and flulike illness associated with the bite of the Lone Star tick *(Amblyomma americanum)* in eastern, southeastern, and south-central U.S.

SYNONYMS

Master disease
Southern Lyme disease

ICD-10CM CODE

A93.8 Other specified arthropod-borne viral fevers

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown as not a reportable disease in the U.S.
PEAK INCIDENCE: As it is temporally associated with tick bites, occurs more often in spring and summer
RISK FACTORS: Activities that lead humans to enter wooded areas where the ticks reside, such as hiking, lawn care, hunting, and walking in the woods

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The rash of STARI is an expanding erythematous lesion (Fig. E1) with irregular borders and central clearing that develops around the site of the Lone Star tick bite. Usually appears within 7 days of the bite and can expand to a diameter of 8 cm or more. It is described as being similar to erythema migrans rash of Lyme disease.
- Other associated symptoms include headache, fatigue, generalized achiness, and/or nausea similar to Lyme disease but without clinical progression or complications.

ETIOLOGY

The cause of STARI remains unknown. At one point a putative causative organism, *Borrelia lonestari,* was identified but it has never been isolated from a human patient. The organism has been isolated in Lone Star ticks (Fig. E2) and deer.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Lyme disease: Caused by the bite of the *Ixodes scapularis* tick and also causes a similar rash called erythema migrans. Causative organism is *Borrelia burgdorferi.*

WORKUP

Diagnosis should be considered in a patient from geographic areas that harbor the Lone Star tick and have a compatible rash, clinical syndrome, and a recent tick bite.

LABORATORY TESTS

- There is no definitive serology test for STARI.
- The ELISA for Lyme disease may be equivocal or weakly positive in patients with STARI but the Lyme Western blot test and Lyme C6 peptide assay will be negative.

TREATMENT

Doxycycline 100 mg orally twice a day for 10 days has been shown to produce rapid resolution of symptoms. This is also the antibiotic used for Lyme disease. For patients allergic to doxycycline or pregnant women or small children, amoxicillin can be used. Adults: 500 mg PO 3× a day.

PEARLS & CONSIDERATIONS

COMMENTS

A study by Wormser et al looked at the differences between STARI and Lyme disease:

- Patients with STARI were more likely to recall tick bite than patients with Lyme disease.
- The time period from tick bite to onset of skin lesion was shorter in STARI (average of 6 days).
- STARI patients with an erythema migrans rash were less likely to have other symptoms than were Lyme disease patients with erythema migrans rash.
- STARI patients were less likely to have multiple skin lesions, had lesions that were smaller in size than Lyme patients (6 to 10 cm for STARI vs. 6 to 28 cm for Lyme disease), and had lesions that were more circular and with more central clearing.
- With antibiotic therapy, patients with STARI had resolution of symptoms faster than patients with Lyme disease.

PREVENTION

Insect repellants can be useful in preventing attachment of the tick. Examples include DEET, picaridin, oil of lemon eucalyptus (OLE) or PMD, and the synthetic version of OLE.

FIG. E2 Tick vector for southern tick-associated rash illness.

BASIC INFORMATION

DEFINITION

Spasticity is an exaggerated tone that displays a velocity-dependent increase in resistance of muscles to a passive stretch stimulus.

SYNONYM

Hypertonicity

ICD-10CM CODES

G80.9	Cerebral palsy, unspecified
G81.10	Spastic hemiplegia affecting unspecified side
G83.9	Paralytic syndrome, unspecified
M62.838	Other muscle spasm
R25.0	Abnormal head movements
R26.0	Ataxic gait

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Spasticity affects between 47% and 70% of people with multiple sclerosis, 32% to 36% of those with spinal cord injury, approximately 20% of those with stroke, more than 90% with cerebral palsy, and approximately 50% of patients with traumatic brain injury.

PREDOMINANT SEX AND AGE: Spasticity is not affected by sex, race, or age group, nor is it more prevalent in any of those groups.

RISK FACTORS: Central nervous system diseases, including multiple sclerosis, stroke, spinal cord injury, cerebral palsy, traumatic brain injury.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patient may present with impaired gait, impaired limb function, decreased mobility, or discomfort due to increased muscle tone.
- While increased tone may preserve strength in the affected muscles, function may be impaired, especially fine motor. Examine active and passive motion, reflexes, and functions:
  1. Strength may be normal or decreased. Isometric strength is typically greater than concentric strength.
  2. Tone may be variably increased to passive range of motion (modified Ashworth scale; see Table E1).
  3. Reflexes are typically brisk.
  4. Patient may have accompanying extensor plantar signs, clonus, or spontaneous flexor spasms.
  5. Function may be impaired or enhanced due to increased tone.

ETIOLOGY

Upper motor neuron injury, most commonly due to multiple sclerosis, stroke, spinal cord injury, cerebral palsy, traumatic brain injury

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Rigidity, clonus, dystonia, dyskinesia, myotonia, tetanus, muscle contracture, cramps

WORKUP

- A diagnosis is established clinically.
- Investigate reversible exacerbating causes of spasticity: Underlying infection, bladder distention, bowel impaction, fracture, pain.

LABORATORY TESTS

Urinalysis, complete blood count, metabolic panel

IMAGING STUDIES

Chest x-ray, abdominal x-ray series, bladder ultrasound

TREATMENT

First treat reversible causes of spasticity (see "Workup"), then proceed to physical and pharmacologic therapeutics. Lastly, consider surgical intervention in severe, refractory cases.

NONPHARMACOLOGIC THERAPY

- Physical therapeutics include range of motion and muscle stretching, serial casting or orthotics, muscle cooling, electrical stimulation.
- Surgical procedures include tenotomy, tendon lengthening, and tendon transfers. More invasive surgical interventions include peripheral neurectomy, myelotomy, and rhizotomy.

ACUTE GENERAL Rx

- Oral medications: Baclofen, tizanidine, diazepam, dantrolene (Table E2)
- Other interventions: Intrathecal baclofen, botulinum toxin intramuscular injections, chemical nerve blocks (with bupivacaine, phenol, or ethyl alcohol)

COMPLEMENTARY & ALTERNATIVE MEDICINE

EMG biofeedback

DISPOSITION

Typically nonprogressive, but medications may lose efficacy after long duration of use. Drug holidays (with use of alternative spasmolytic) may be beneficial.

REFERRAL

- Physicians: Neurologist or physiatrist with expertise in botulinum toxin injection and/or intrathecal spasmolytic therapy is recommended when oral medications are ineffective or not tolerated.
- Physical and occupational therapy.

TABLE E1 Modified Ashworth Scale

0	No increase in muscle tone
1	Slight increase in muscle tone, manifested by a catch and release or by minimal resistance at the end range of motion when the part is moved in flexion or extension/abduction or adduction
1+	Slight increase in muscle tone, manifested by a catch, followed by minimal resistance throughout the remainder (less than half) of the range of motion
2	More marked increase in muscle tone through most of the range of motion, but the affected part is easily moved
3	Considerable increase in muscle tone, passive movement is difficult
4	Affected part is rigid in flexion or extension (abduction or adduction)

From Stein J: Spasticity. In Frontera WR et al (eds): *Essentials of physical medicine and rehabilitation,* ed 2, Philadelphia, 2008, WB Saunders.

TABLE E2 Commonly Used Oral Spasmolytic Medications

Medication	Mechanism of Action	Starting Dose	Maximum Dose	Common Side Effects	Considerations*
Baclofen	GABA-B agonist	5 mg tid	20 mg qid†	Sedation, rare hepatotoxicity	Cognitive impairment
Diazepam	GABA-A agonist	2 mg bid	10 mg qid	Sedation, dependence or tolerance	History of substance abuse, cognitive impairment
Tizanidine	Alpha-2 agonist	2 mg tid	12 mg tid	Sedation, hypotension, hepatotoxicity	Cognitive impairment
Dantrolene	Blocks Ca^{2+} release from sarcoplasmic reticulum	25 mg daily	100 mg qid	Weakness, hepatotoxicity	Liver disease

*Baclofen, diazepam, and tizanidine are centrally acting and may exacerbate cognitive impairment. Dantrolene acts peripherally; however, it has the rare but fatal side effect of hepatotoxicity.
†Approved by the U.S. Food and Drug Administration only up to 80 mg/day, but many clinicians exceed this in patients who tolerate this medication well but do not respond to smaller doses.
bid, Twice a day; *qid,* four times a day; *tid,* three times a day. Modified from Stein J: Spasticity. In Frontera WR et al (eds): *Essentials of physical medicine and rehabilitation,* ed 2, Philadelphia, 2008, WB Saunders.

PEARLS & CONSIDERATIONS

- Assess whether the spasms recently increased in severity or intensity (as would occur with reversible exacerbating causes).
- Consider whether patient's tone is beneficial or detrimental to patient's functionality or overall health status.
- Spasticity may assist posture and mobility, as well as maintain muscle mass and bone mineralization, reduce dependent edema, and prevent deep venous thrombosis.
- Spasticity may impair patient's functionality, interfere with activities of daily living, interfere with sleep, and cause discomfort.
- Monitor liver function with dantrolene and tizanidine, as these drugs may cause hepatotoxicity.

AUTHOR: **Joseph S. Kass, MD, JD, FAAN**

Spina Bifida

BASIC INFORMATION

DEFINITION

Spina bifida refers to a group of neural tube disorders that involve the spinal column and include spina bifida occulta and spina bifida cystica (Fig. E1). Anencephaly and cranium bifidum (i.e., encephalocele) are also classified as neural tube disorders.

Spina bifida occulta is a midline defect of closure of the posterior vertebral arches and laminae and usually involves the L5 to S1 area of the spinal cord.

Spina bifida cystica includes both meningocele and myelomeningocele. Meningocele is a midline defect in which only the meninges herniate through the posterior vertebral arch defect with a normal spinal cord in a normal position in the spinal canal; this condition makes up about 5% of cases of spina bifida cystica. Myelomeningocele is the most severe form of disease in the spectrum of spina bifida. The meninges, fragments of bone and cartilage, and the spinal cord herniate through the vertebral arches or the skin; this condition makes up about 95% of cases. Most of these defects (~75%) are located in the lumbosacral area (Figs. E2 and E3).

SYNONYMS

Dysraphism
Meningomyelocele
Neural tube disorders

ICD-10CM CODES

Q76.0 Spina bifida occulta
Q05.8 Sacral spina bifida without hydrocephalus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Spina bifida occulta: 10% of the general pediatric population
- Spina bifida cystica: 0.15% of Caucasians, 0.04% of African Americans
- Highest in Ireland and lowest in Japan
- Within the U.S., rate is approximately 0.2 per 1000 live births and is much higher in the Latino population
- Influenced by season, economic status, maternal age, heat exposure, and history of prior children with neural tube defects
- Neural tube defects are the second-most common congenital anomaly (after cardiac malformations) and are the cause of chronic disability of between 70,000 and 100,000 individuals in the U.S.

PREDOMINANT SEX: Females are affected more frequently than males.

RISK FACTORS:

- Nutritional deficiency (specifically folate)
- Prior children with neural tube defects (risk increases 1.5% to 2%)
- If two prior children had spinal column defects, the risk increases 6% to 10%.

GENETICS:

- Unknown.
- New data suggest that epigenetic alteration in placental DNA methylation may be associated with spina bifida, particularly with genes involving *TRIM 26* and *GNAS.*

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Spina bifida occulta:
  1. Most patients are asymptomatic and have a normal neurologic examination.
  2. In some cases, patients may have a patch of hair, a lipoma, skin discoloration, or a dermal sinus overlying the defect.
  3. The condition is occasionally associated with syringomyelia, diastematomyelia, and a tethered cord.
- Meningocele:
  1. Patients typically have a normal neurologic examination; however, lesions may be accompanied by tethering, syringomyelia, or diastematomyelia.
  2. Constipation or bladder dysfunction can develop as a result of an enlargement of the lesion.
- Myelomeningocele:
  1. The lesion can be completely exposed, or it may have a skinlike membrane.
  2. The extent of the neurologic deficits depends on the level of the lesion.
     a. Thoracolumbar: Hypertonic or spastic bladder with normal anal tone

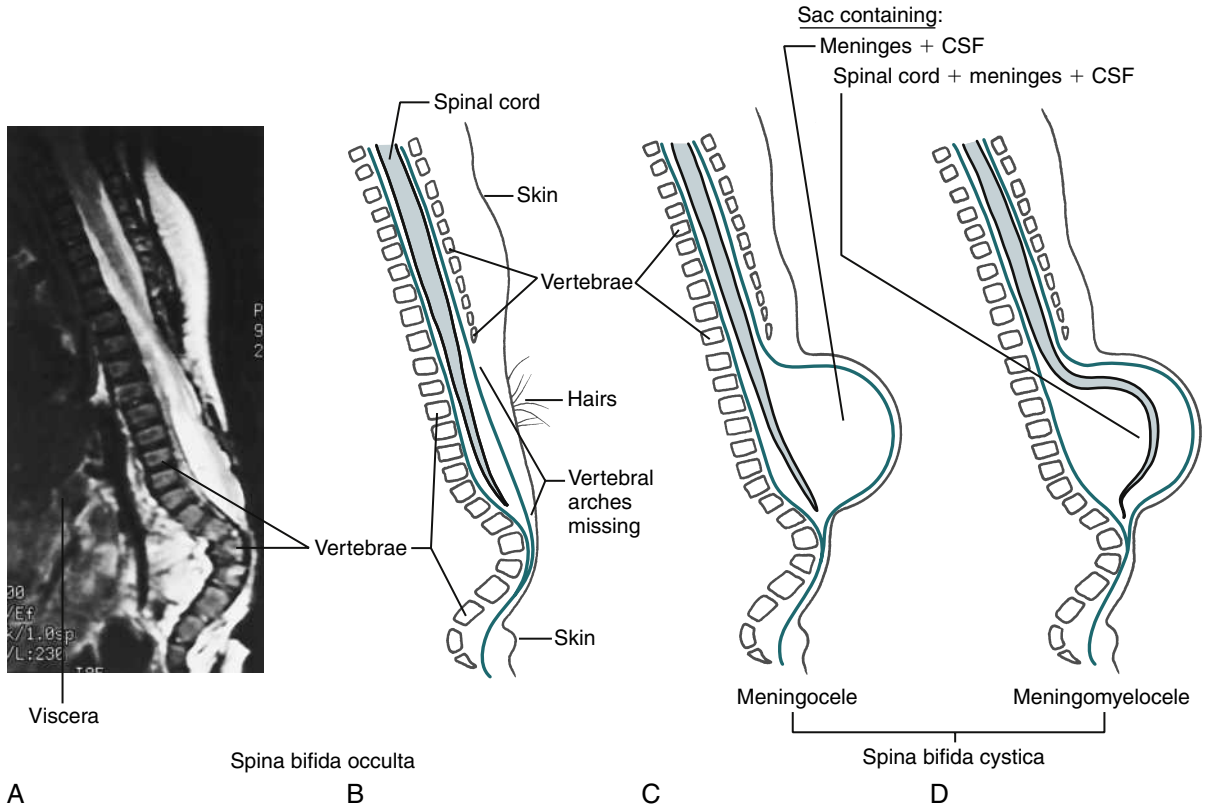

FIG. E1 Sagittal views of spina bifida malformations. Magnetic resonance image **(A)** and corresponding views showing spina bifida occulta **(A, B)** and spina bifida cystica (**C,** meningocele; **D,** meningomyelocele). *CSF,* Cerebrospinal fluid. (From Haines DE: *Fundamental neuroscience for basic and clinical applications,* ed 3, Philadelphia, 2006, Churchill Livingstone.)

b. Below L2: Flaccid tone; areflexic paraparesis; sensory loss in L3 to L4 dermatomes; bladder and bowel incontinence; and poor anal sphincter tone, which can result in rectal prolapse
c. Below S3: Motor deficits are absent; bladder and anal sphincter paralysis with saddle anesthesia

- Joint deformities include contractures, hip dislocations, scoliosis, clubfoot, and rocker-bottom foot.
- Hydrocephalus with Chiari malformations type II occurs in up to 90% of lumbosacral myelomeningoceles, and it is seen in more than half of cases at birth.
- Tethered cord disease manifests with a loss of motor function, spasticity with contractures, rapid progression of scoliosis with bent posture, back pain, and changes in urodynamics.

FIG. E2 Lumbosacral myelomeningocele covered by an epithelialized membrane. (From Kliegman RM [ed]: *Nelson textbook of pediatrics,* ed 18, Philadelphia, 2007, Saunders.)

- The condition is associated with disorders of cell migration that cause brain malformations, including heterotopia and schizencephaly.
- With this disease, there may also be multiorgan developmental disease (e.g., renal agenesis/anomalies, duodenal atresia, cardiac malformations, tracheoesophageal fistulas).

ETIOLOGY

- The posterior neuropore closes at about 26 to 28 days of gestation, which is typically prior to maternal knowledge of the pregnancy. The failure of the closure results in any of the neural tube disorders, with the severity being dependent on the stage of development at closure (i.e., earlier in development results in spina bifida cystica vs. spina bifida occulta).
- The cause of the failure to close is unknown, but it is thought to be multifactorial and to involve genetic defects, environmental toxins, and folate deficiency.

Dx DIAGNOSIS

This section will be further divided into prenatal diagnosis and diagnosis after birth.

PRENATAL DIAGNOSIS

- All pregnant women should be offered screening for NTDs. Unlike screening for fetal aneuploidy in women of advanced maternal age, selective screening based on maternal risk factors is not effective, because 90% to 95% of NTDs will occur in pregnancies with no risk factors. Thus, universal NTD screening would identify the majority of affected pregnancies.
- The benefit of screening is that early diagnosis can allow parents the option of terminating the pregnancy, deciding on a therapeutic intervention such as fetal surgery, or preparing for the birth of a child with an NTD. Furthermore, advanced knowledge of NTD may affect the mode and site of delivery, as these infants should be delivered at a center with level III neonatal intensive care unit and pediatric neurosurgery services.
- There are two approaches to prenatal screening for NTDs: Measurement of maternal serum alpha-fetoprotein (MSAFP) and ultrasound (screening and diagnostic). While intricate details of MSAFP interpretation and prenatal ultrasonographic screening for NTDs are beyond the scope of this book, MSAFP screening basics are discussed in the following.
  1. MSAFP screening is ideally performed at 16 to 18 wks gestation but can be performed as early as 15 wk or as late as 20 wk. First-trimester screening is not recommended, due to low sensitivity.
  2. It is important to consider gestational age, multiple pregnancy, maternal weight, and maternal diabetes mellitus when interpreting MSAFP values, as these can all affect interpretation. Furthermore, abdominal wall defects are commonly associated with elevated MSAFP.

DIAGNOSIS AFTER BIRTH

DIFFERENTIAL DIAGNOSIS: Isolated to this group of disorders

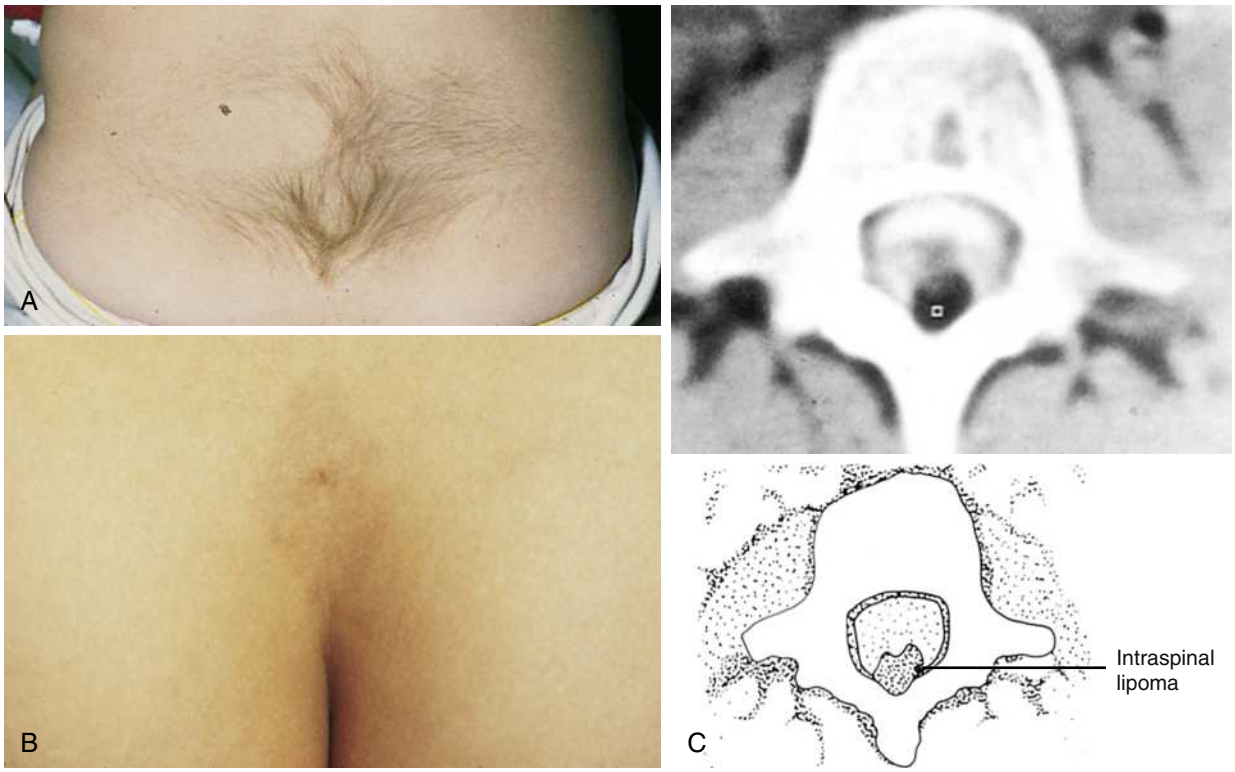

FIG. E3 Examples of cutaneous malformations associated with spina bifida occulta. A, Tuft of hair. **B,** Sacral lipoma. **C,** Sinus tract that communicates with a dermoid tumor. (From Zitelli BJ, Davis HW [eds]: *Atlas of pediatric physical diagnosis,* ed 5, Philadelphia, 2007, Saunders.)

WORKUP

- Spina bifida occulta: None, unless foot deformities, neurogenic bladder, or neurologic deficits develop, which would be concerning for spinal cord pathology
- Spina bifida cystica: Mostly includes imaging studies

LABORATORY TESTS

None

IMAGING STUDIES

- Ultrasound of affected areas
- MRI of head and spine
- Computed tomography is a quicker study and would not require sedation; however, this method exposes the patient to radiation and therefore should be minimized

Rx TREATMENT

- Spina bifida occulta: If asymptomatic with normal examination, none
- Meningocele: None
- Myelomeningocele: Antiepileptic medications, if warranted

NONPHARMACOLOGIC THERAPY

- Spina bifida occulta: There is no nonpharmacologic therapy used for this condition, unless the patient develops neurologic disease that is suggestive of underlying spinal cord disease.
- Meningocele: Most of these defects are covered by skin, so there is minimal risk of infection. If the patient has a normal examination with full-thickness skin, surgery can be delayed. However, if cerebrospinal fluid begins to leak or if the skin is thin, then immediate surgical correction is warranted.
- Myelomeningocele: Initial sac closure with a ventriculoperitoneal shunt is usually performed during the first 48 hr of life. It is important to use nonlatex gloves and equipment to minimize the risk of latex sensitization in these infants, as they are at increased risk for developing life-threatening latex allergy.
- The in utero closure of spinal lesions has been successful in a few centers, but there is a lack of evidence to support this procedure. The theory is that early closure possibly results in less severe motor disease, joint deformities, and sensory loss.

CHRONIC Rx

- Involves a multidisciplinary approach that includes primary care, neurology, urology, orthopedic surgery, neurosurgery, and physical and occupational therapy
- Bladder catheterization to ensure complete emptying of urinary bladder and minimization of renal scarring
- Urodynamic evaluations
- Bowel training with stool softeners and enemas (an appendicostomy may be placed for antegrade enemas, if warranted)
- The goal is to prevent the further loss of function and to maximize ambulation:
  1. Close monitoring via physical examination for further worsening of clubfoot, spasticity, sensory loss as a result of possible shunt malfunction, or tethering of cord, which would warrant neurosurgical intervention
  2. Orthotics
  3. Physical and occupational therapy
- Frequent skin examinations to monitor for decubitus ulcer formation

DISPOSITION

- 70% of patients have normal intelligence; this is affected by episodes of meningitis and encephalitis.
- Most patients with spina bifida have normal intelligence, but almost all will have some degree of learning disability, including attention deficits, memory problems, and poor executive functioning.
- Seizures occur in 10% to 25% of children with myelomeningocele and are correlated to poor cognitive performance.

PEARLS & CONSIDERATIONS

PREVENTION

All women of childbearing age should take a daily multivitamin for folate supplementation (0.4 mg/day), because more than half of pregnancies are unplanned, and the greatest benefit is seen when supplements are taken for about 1 mo before conception. Daily dose should be increased to 0.6 mg/day during pregnancy. Women who have had a previous child with NTD and those taking medications that affect folate metabolism (e.g., valproic acid, carbamazepine, methotrexate, sulfamethoxazole/trimethoprim) are recommended to take folic acid supplementation of 4 to 5 mg per day prior to conception to reduce occurrence/recurrence of NTD. This high dose should be taken as folic acid alone, not as a multivitamin, as there is a risk of excessive vitamin intake with ingestion of several multivitamins, such as vitamin A, which is dangerous during pregnancy.

BASIC INFORMATION

DEFINITION

- Spinal cord compression is characterized by direct compression of the spinal cord within the spinal canal. This may result in loss of neurologic function from compression of the spinal cord in the cervical, thoracic, and upper lumbar spinal canal. Compression may also occur at the cauda equina in the lower lumbar spinal canal, which is anatomically below the level of the spinal cord. Fig. 1 illustrates a schematic demarcation of principal dermatomes shown as distinct segments. Depending on the underlying etiology, symptoms may develop gradually or acutely and may result in complete or incomplete deficits. Neurologic deficits related to compression of the cord itself are referred to as myelopathy, whereas deficits caused by compression on nerve roots are described as radiculopathy.
- Signs and symptoms of myelopathy:
  1. Upper motor neuron signs (Hoffman sign, inverted radial reflex, Babinski sign, spasticity, hyperreflexia, clonus) in chronic cases
  2. Weakness
  3. Sensory deficits
  4. Clumsiness, difficult ambulation, ataxic gait (secondary to loss of proprioception in legs)
- Signs and symptoms of radiculopathy:
  1. Lower motor neuron signs (hyporeflexia, hypotonicity, fasciculations, muscle atrophy)
  2. Weakness
  3. Sensory deficits

Incomplete spinal cord lesions may classically present in distinct syndromic patterns (Table 1), for example, as follows:

- Anterior cord syndrome
- Central cord syndrome (most common)
- Cauda equina syndrome (not a true example of spinal cord compression but rather of cauda equina compression, affecting lower motor neurons in lumbosacral nerve roots)
- Conus medullaris syndrome
- Brown-Séquard syndrome

SYNONYMS OR RELATED TERMS

Central cord syndrome
Anterior cord syndrome
Brown-Séquard syndrome
Acute spinal cord compression
Cauda equina syndrome
Conus medullary syndrome

ICD-10CM CODES	
S14.13XX	Anterior cord syndrome
G83.81	Brown-Séquard syndrome
G83.4	Cauda equina syndrome
S14.12XX	Central cord syndrome
G95.81	Conus medullaris syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

Dependent on etiology of cord compression

DEGENERATIVE SPINE DISORDERS

May affect the cervical, thoracic, and/or lumbar spine. Underlying pathology involves changes in keratin sulfate-to-chondroitin sulfate ratio in intervertebral disks with aging. This leads to a cascade of secondary events, including loss of disk height, disk herniation, spondylosis, increased intersegmental motion, formation of osteophytes, ligamentum flavum hypertrophy, and arthrosis of the facet joints. Compression of the nerve roots and/or spinal cord may result.

Spinal cord and nerve root compression from degenerative conditions are more common with increasing age, although any age group may be affected. Specific epidemiology and demographics are dependent on the type of degenerative changes.

TUMOR

Epidemiology dependent entirely on tumor type. Malignant tumors in the spine are most commonly metastatic disease, although primary musculoskeletal tumors are possible. The spine is the third-most common site for tumor metastases, after the lung and liver. Common metastatic lesions to the spine include lung cancer, breast cancer, prostate cancer, cancer of the GI tract, multiple myeloma, and lymphoma.

INFECTION

Diskitis/osteomyelitis may progress to epidural abscess, causing spinal cord or cauda equina compression. If not adequately addressed in a timely manner, this may result in permanent neurologic deficit. Epidural abscess incidence is approximately 0.2 to 3.0 per 10,000 hospital admissions. *Staphylococcus aureus* is the most common offending organism. Risk factors include increasing age, diabetes mellitus, end-stage renal disease, chronic hepatitis/cirrhosis, known endocarditis, immunocompromise, and IV drug abuse.

SPINAL CORD INJURY

Occurred most commonly in males with a mean age of 37 yr in 2010. Alcohol plays a major role in at least 25% of spinal cord injury (SCI).

INCIDENCE: 12,400 new cases/yr in 2010 in the U.S.

PREVALENCE: 250,000 persons in 2005 in the U.S.

COST (IN U.S.): >$5 billion/yr

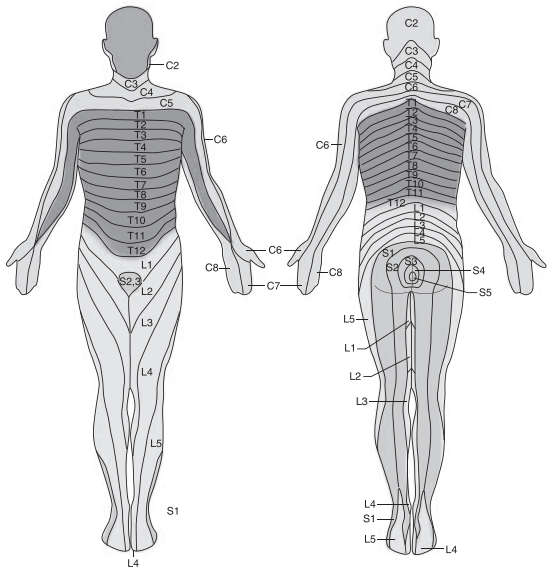
RISK FACTORS: Underlying spinal disease can predispose to SCI:

- Inflammatory spondyloarthropathies, especially ankylosing spondylitis
- Diffuse idiopathic skeletal hyperostosis (DISH)
- Congenital spinal disorders
- Preexisting spinal canal stenosis or compromise
- Atlantoaxial instability
- Osteoporosis
- Rheumatoid arthritis (cervical spine)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical features reflect the amount of spinal cord involvement:

- Weakness, sensory changes (dependent on level of compression/lesion/injury).
- Myelopathy if cord involvement, radiculopathy if nerve root involvement (may involve both).



Levels of principal dermatomes

C5	Clavicles
C5,6,7	Lateral parts of upper limbs
C8, T1	Medial sides of upper limbs
C6	Thumb
C6,7,8	Hand
C8	Ring and little fingers
T4	Level of nipples
T10	Level of umbilicus
T12	Inguinal or groin regions
L1,2,3,4	Anterior and inner surfaces of lower limbs
L4,5 S1	Foot
L4	Medial side of great toe
S1,2, L5	Posterior and outer surfaces of lower limbs
S1	Lateral margin of foot and little toe
S2,3,4	Perineum

FIG. 1 Schematic demarcation of levels of principal dermatomes shown as distinct segments. There is actually considerable overlap between any two adjacent dermatomes. (From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2011, Saunders.)

TABLE 1 Spinal Cord Syndromes

Syndrome	Sensory	Motor	Sphincter Involvement
Central cord syndrome	Variable	Upper extremity weakness, distal > proximal	Variable
Brown-Séquard syndrome	Ipsilateral position and vibration sense loss Contralateral pain and temperature sensation loss	Motor loss ipsilateral to cord lesion	Variable
Anterior cord syndrome	Loss of pin and touch sensation Vibration, position sense preserved	Motor loss or weakness below cord level	Variable
Transverse cord syndrome—complete	Loss of sensation below level of cord injury	Loss of voluntary motor function below cord level	Sphincter control lost
Cauda equina syndrome	Saddle anesthesia may be present, or sensory loss may range from patchy to complete transverse pattern	Weakness may be of lower motor neuron type	Sphincter control impaired

From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, WB Saunders.

TABLE 2 Physical Examination Findings Associated with Vertebral Fractures and Spinal Cord Injuries

Injury	Physical Examination Area	Associated Findings
Vertebral fracture	Spine	Tenderness of the neck and/or back. Examine the entire spine because vertebral fractures may occur in multiples.
	Neurologic	See "Spinal cord injury" later.
	Chest	*Thoracic spine fractures:* Check for chest tenderness, unequal breath sounds, and arrhythmia, which are suggestive of an associated intrathoracic injury or myocardial contusion.
	Abdomen/pelvis	*Thoracolumbar and lumbar spine fractures:* Check for abdominal or pelvic tenderness. A transverse area of ecchymosis on the lower abdominal wall (seat belt sign) increases the chance of an abdominopelvic injury.
	Extremity	*Thoracolumbar and lumbar spine fractures*: Check for calcaneal tenderness because 10% of calcaneal fractures are associated with a low thoracic or lumbar fracture. Mechanistically, these areas are fractured as a result of axial loading.
Spinal cord injury	Neurologic, motor (anterior column)	Assess motor function on a scale of 0 to 5. The *motor level* is defined as the most caudal segment with at least 3/5 strength. Injuries to the first eight cervical segments result in tetraplegia (previously known as quadriplegia); lesions below the T1 level result in paraplegia.
	Neurologic, sensory (spinothalamic tract)	Assess sensory function via pinprick and light touch on the following scale: 0 = absent; 1 = impaired; 2 = normal. The *sensory level* is defined as the most caudal segment of the spinal cord with normal sensory function. The highest intact sensory level should be marked on the patient's spine to monitor for progression.
	Neurologic, sensory (dorsal column)	Assess vibratory sensory function on a scale of 0 to 2 by using a tuning fork over bony prominences. Assess position sense (proprioception) by flexing and extending the great toe.
	Neurology, deep tendon reflex	On a scale of 0 to 4, assess the deep tendon reflexes in the upper (biceps, triceps) and lower (patellar, Achilles) extremities.
	Anogenital	Assess rectal tone, sacral sensation, signs of urinary or fecal retention or incontinence, and priapism. Also check the anogenital reflexes. An *anal wink* (S2-S4) is present if the anal sphincter contracts in response to stroking the perianal skin area. The *bulbocavernosus reflex* (S3-S4) is elicited by squeezing the glans penis or clitoris (or pulling on an inserted Foley catheter), which results in reflexive contraction of the anal sphincter.
	Head-to-toe examination	A spinal cord injury may mask a patient's ability to perceive and localize pain. Imaging of high-risk areas, such as the abdomen, and areas of bruising or swelling may be required to exclude occult injuries.

From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

- ***Central cord syndrome (most common incomplete spinal cord injury):*** Motor impairment greater in upper than in lower extremities, variable degree of sensory loss below the injury level. Weakness and poor hand dexterity are especially common. Classically occurs after mild trauma including cervical hyperextension in the setting of preexisting cervical spondylosis.
- ***Anterior cord syndrome (worst prognosis of incomplete spinal cord injury):*** Affects the anterior or ventral two thirds of the spinal cord, sparing the dorsal columns. May be caused by a vascular injury to the anterior spinal artery or by a flexion/compression injury. Impairment usually is worse in the lower extremities than upper extremities. Physical manifestations include motor, pain, and temperature loss below the lesion. Proprioception and vibratory sense may be preserved as dorsal columns are preserved.
- ***Brown-Séquard syndrome:*** Rare in isolation. Caused by injury to half of the spinal cord and resulting in the loss of motor function, position, vibration, and light touch on the side of injury, as well as loss of pain and temperature sense on the contralateral side. Typically, secondary to a knife wound.
- ***Conus medullaris syndrome:*** Results in variable motor loss in the lower extremities with loss of bowel and bladder function. In general, more bowel and bladder is affected earlier than motor.
- ***Cauda equina syndrome:*** Low back pain, weakness in bilateral lower extremities, saddle anesthesia, and loss of voluntary bladder and/or bowel control, often presenting as bladder retention and/or bowel incontinence.

ETIOLOGY

- Trauma (most SCIs result from high-speed motor vehicle accidents, falls, sports injuries, or violence)
- Tumor
- Infection (e.g., epidural abscess)
- Inflammatory processes
- Degenerative disk disease with associated spinal stenosis
- Acute disk herniation
- Cystic abnormalities
- Ankylosing spondylitis, DISH. Patients with underlying DISH or ankylosing spondylitis are at high risk of SCI with otherwise relatively minor fractures of the spine
- Table 2 summarizes physical examination findings associated with vertebral fractures and spinal cord injuries

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

See "Synonyms or Related Terms."

WORKUP

- Signs and symptoms of spinal cord or cauda equina compression often indicate urgent surgical conditions and thus require urgent imaging and early referral for assessment by a spine specialist.

- In cases of acute trauma in which spinal cord injury is suspected, patient should undergo full trauma evaluation following advanced trauma life support protocol in emergency room setting. With suspected injury to the cervical spine, the patient should be immobilized in a hard cervical collar or in-line traction at all times during evaluation. Log-roll precautions may be indicated as well to immobilize the spine during acute injury evaluation.
- Inflammatory labs will usually be elevated both in cases of trauma and infectious processes. Laboratory tests ordered should be specific to the suspected etiology or differential diagnosis for spinal cord compression.

IMAGING STUDIES

- Signs and symptoms of spinal cord compression in most cases will mandate advanced imaging, often including CT and CT myelogram and/or MRI.
- Plain x-rays may be helpful; however, normal plain films do not negate the need for further advanced imaging in the setting of signs and symptoms of spinal cord compression or spinal cord injury. This is especially true in the setting of ankylosing spondylitis or DISH.
- In the trauma setting, after primary and secondary surveys, fine-cut helical CT scans with axial, coronal, and sagittal reconstructions have replaced plain cervical radiographs in most trauma centers as the initial evaluation of choice in detecting fractures of the cervical spine.
- Detection of injury to any part of the spine during trauma evaluation mandates full imaging evaluation of the entire spine, as noncontiguous injuries are common.
- While CT scan is excellent at imaging bony structures and detecting fractures, MRI provides more detailed imaging of the soft-tissue structures, including neural structures, discoligamentous structures, the posterior ligamentous complex, and paraspinal soft tissues. MRI is very sensitive for detecting ligamentous injury, spinal cord edema, spinal cord compression from soft-tissue structures, epidural hematoma, diskitis, osteomyelitis, and epidural abscess. Of note, gadolinium contrast may increase the sensitivity of the MRI study for the detection of tumors or infections.

Rx TREATMENT

- Depending on the etiology of spinal cord compression as well as the specific signs and symptoms during physical examination and history-taking, urgent surgical decompression and/or stabilization may be indicated. Referral to a spine specialist is indicated in most cases of spinal cord compression.
- Corticosteroids: Controversial in cases of acute spinal cord injury. Methylprednisolone was thought to reduce the amount of secondary injury that occurs after SCI and was previously used in many trauma centers. However, current evidence is insufficient to support corticosteroids for this use, and most spine trauma centers no longer utilize steroids in cases of acute spinal cord injury.

Vasopressors: Current evidence supports the use of vasopressors in cases of spinal cord injury to maintain spinal cord perfusion and to prevent ischemic damage to the cord. The ideal mean arterial pressure and duration of treatment are yet to be defined. Both the treatment modality and the injury itself mandate admission to ICU level of care in most cases for close monitoring.

DISPOSITION

Indicators regarding prognosis:

- Patients with acute traumatic SCI need monitoring in the ICU and evaluation for potential life-threatening complications, including cardiovascular instability and respiratory failure.
- In general, the greater the distal motor and sensory sparing, the greater the expected recovery.
- In most cases of spinal cord compression and/or spinal cord injury, the primary goal of surgical decompression and/or stabilization should be to spare the remaining functional levels and to prevent worsening of the injury. Return of function should not be guaranteed.
- Prophylaxis against deep vein thrombosis and pulmonary embolism should always be provided. In acute injuries to the spine or postoperatively, this may consist of mechanical prophylaxis including TEDs and SCDs. Pharmacologic deep vein thrombosis/pulmonary embolism prophylaxis is often held initially to prevent development of epidural hematoma. The optimal timing for initiation of pharmacologic prophylaxis is controversial, and no strict guidelines are currently in place.

REFERRAL

Signs and symptoms of spinal cord or cauda equina compression often indicate urgent surgical conditions and thus require urgent imaging and early referral for assessment by a spine specialist.

Spinal Epidural Abscess

BASIC INFORMATION

DEFINITION

A spinal epidural abscess (SEA) is a focal suppurative infection occurring in the spinal epidural space.

SYNONYM

SEA

ICD-10CM CODE
G06.1 Intraspinal abscess and granuloma

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):
- 2 to 25 cases/100,000 hospitalized patients/yr
- May be increasing over the past 3 decades

PREDOMINANT AGE:
- Median age of onset approximately 50 yr (35 yr in intravenous drug users)
- Peak incidence in seventh and eighth decades of life

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The presentation of SEA can be nonspecific.
- Fever, malaise, and back pain are the most consistent early symptoms.
- Pain is often focal. It may initially be mild but can progress to become severe.
- As the disease progresses, root pain can occur, followed by motor weakness, sensory changes, bladder and bowel dysfunction, and paralysis.
- Physical findings may be limited to fever or spinal tenderness.
- The evolution to neurologic deficits can occur as quickly as a few hours, or over wks to mos.
- Once paralysis occurs, it may quickly become irreversible without the appropriate intervention.

ETIOLOGY

- SEA most commonly results from hematogenous dissemination.
- Pyogenic bacteria account for the majority of cases in the U.S. Immigrants from TB-endemic areas may present with tuberculous SEAs. Fungi and parasites can also cause this condition. The most common causative organism is *Staphylococcus aureus.* Gram-negative bacilli and anaerobes may be seen if the infection has a urinary or GI source.
- Most posterior SEAs are thought to originate from distant focus (e.g., skin and soft tissue infections), while anterior SEAs are commonly associated with diskitis or vertebral osteomyelitis. No source was found in approximately one third of cases.
- Associated predisposing conditions include diabetes mellitus, alcoholism, cancer, AIDS, and chronic renal failure, or following epidural anesthesia, spinal surgery or trauma, prolonged epidural catheter placement, paraspinal glucocorticoid or analgesic injections, acupuncture, or IV drug use. No predisposing condition is found in approximately 20% of patients.
- Damage to the spinal cord can be caused by direct compression of the spinal cord, vascular compromise, bacterial toxins, and inflammation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Herniated disk
- Vertebral osteomyelitis and diskitis
- Metastatic tumors
- Meningitis

LABORATORY TESTS

- WBC may be normal or elevated.
- ESR and C-reactive proteins are usually elevated.
- Blood cultures are positive in approximately 60% of patients with SEA and should be obtained prior to starting antibiotics.
- CSF cultures are positive in 19%, but lumbar puncture is unnecessary, and may be contraindicated.
- Once imaging is done, CT-guided aspiration or open biopsy should be done to determine causative organism. Abscess content culture is positive in 90% of patients.

IMAGING STUDIES

- MRI with gadolinium is the imaging modality of choice (Fig. 1); CT scan with contrast may show the abscess (Fig. 2) but is less sensitive than MRI.
- CT with myelography is more sensitive for cord compression.

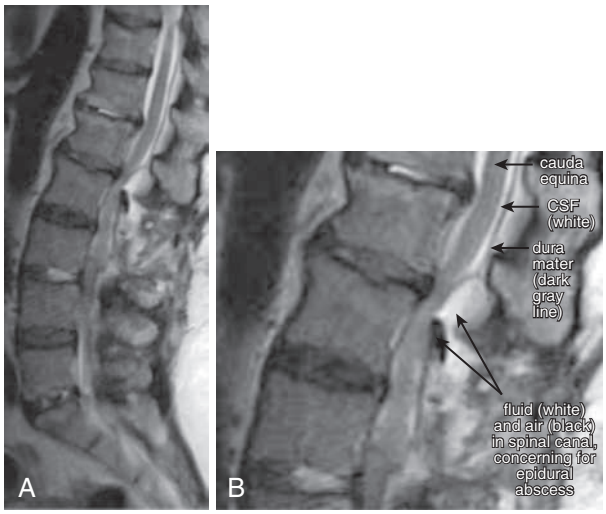

FIG. 1 Same patient as in Fig. 2, in whom noncontrast computed tomography showed air in the spinal canal, concerning for epidural abscess. Magnetic resonance imaging (MRI) of the lumbar spine without contrast was performed, as the patient was in acute renal failure. **A,** This T2-weighted sagittal MRI provides useful information even without gadolinium contrast. **B,** Close-up. On T2-weighted MRI sequences, fluid including cerebrospinal fluid *(CSF)* appears white. Fat-containing tissues such as bone marrow and the spinal cord or cauda equina appear dark gray. Calcified bone appears nearly black due to an absence of resonating protons. Air appears completely black for the same reason. The midline sagittal image shows the cauda equina to be impinged upon by an epidural fluid collection containing air—an epidural abscess. The dura mater is visible as a thin, dark-gray line parallel to the spinal cord. It is indented in the region of the epidural abscess. (From Broder JS: *Diagnostic imaging for the emergency physician*, Philadelphia, 2011, WB Saunders.)

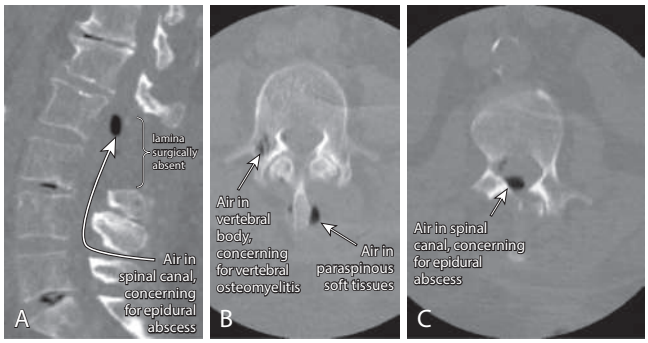

FIG. 2 This 67-yr-old female presented with delirium and fever. 3 mo prior, she had undergone lumbar laminectomy, and her wound had been treated with a wound VAC dressing. Magnetic resonance imaging was not initially available, so noncontrast computed tomography (CT) was performed. Noncontrast CT is excellent at delineating air, which appears black on bone windows. **A,** The midsagittal view demonstrates air *(black)* in the spinal canal at the L2 and L3 levels. On the axial views **(B, C),** air is visible in the spinal canal, in paraspinal soft tissues, and within the vertebral body. These findings are concerning for a paraspinal infection that has developed into an epidural abscess with vertebral osteomyelitis. (From Broder JS: *Diagnostic imaging for the emergency physician*, Philadelphia, 2011, WB Saunders.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Surgical decompression is the mainstay of treatment. Decompression within the first 24 hr has been related to an improved prognosis.
- Nonsurgical treatment is effective in some patients, but failure rate may be excessive. This approach should not be considered and should only be attempted in the absence of signs of compressive myelopathy and with very careful follow-up.

ACUTE GENERAL Rx

- In addition to surgery, antibiotics directed at the most likely organism should be initiated. Fig. 3 describes an algorithm for the management of patients with SEA.
- If the organism is unknown, broad coverage against staphylococci, streptococci, and gram-negative bacilli should be initiated. Empiric antimicrobial intravenous therapy typically includes vancomycin (loading dose: 25 to 30 mg/kg, then 15 to 20 mg/kg q8-12h, aiming for trough levels of 15 to 20) plus an antipseudomonal cephalosporin such as piperacillin/tazobactam at high dose (4.5 g IV q6h) or carbapenem such as meropenem (1 to 2 g IV q8h) or imipenem. The regimen can be adjusted according to culture results. Therapy should continue for at least 4 to 6 wk.

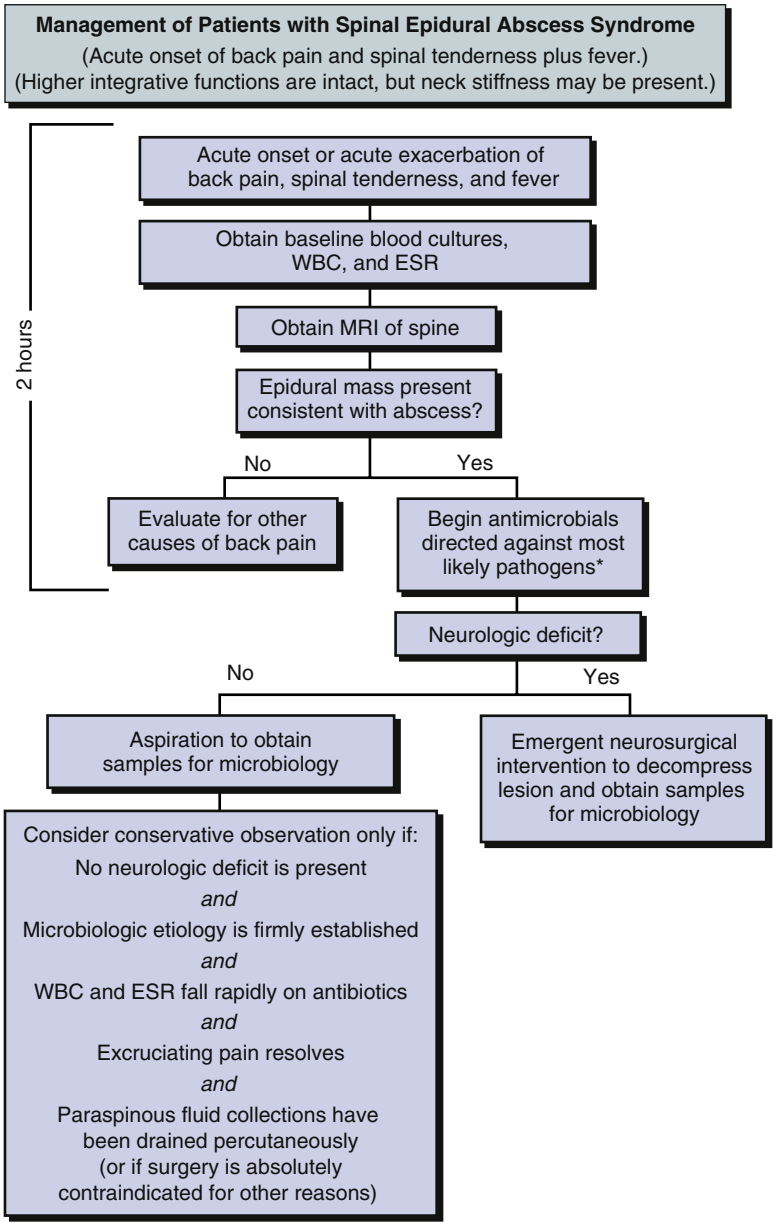

FIG. 3 Algorithm for the management of patients with spinal epidural abscess syndrome. If magnetic resonance imaging *(MRI)* cannot be performed, myelography, high-contrast computed tomography (CT), or CT-myelography may be an acceptable alternative to localize an epidural abscess. *If abscess drainage can be performed promptly, antimicrobial drugs may be withheld until specimens for microbial analysis are obtained. *ESR,* Erythrocyte sedimentation rate; *MRI,* magnetic resonance imaging; *WBC,* white blood cell. (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.)

CHRONIC Rx

Neurologic deficits may remain despite aggressive treatment.

DISPOSITION

Irreversible paralysis and death can occur in up to 25% of patients.

REFERRAL

All cases should be referred to a neurosurgeon and an infectious disease specialist.

PEARLS & CONSIDERATIONS

- Follow-up imaging with MRI is not necessary unless patient develops new neurologic signs or symptoms, has poor clinical response, or has persistent elevation of inflammatory markers.
- It is critically important to recognize this process early; the prognosis is generally excellent if treatment is initiated while symptoms are localized and before evidence of myelopathy develops.
- The likelihood of success postsurgery is low in patients who have developed complete paralysis for longer than 36 hours.

Spinal Stenosis, Cervical Spine

BASIC INFORMATION

DEFINITION

Cervical spinal stenosis is defined as any abnormal narrowing of the cervical spinal canal. Radiographically, absolute cervical stenosis is defined as a canal diameter less than 10 mm, and relative stenosis is defined as a canal diameter between 10 and 13 mm. Stenosis of any part of the spinal canal (cervical, thoracic, or lumbar) may be congenital or, more commonly, acquired. Congenital spinal stenosis is due to a skeletal hypoplasia, whereas acquired stenosis is a multifactorial process that usually evolves with advanced age and as a result of degenerative disease. Symptoms arising from cervical spinal stenosis are due to compression of the exiting nerve root or on the spinal cord itself.

SYNONYMS

Cervical myelopathy
Cervical radiculopathy
Degenerative disease of the spine
Spinal foramina narrowing

ICD-10CM CODES

M47.12	Other spondylosis with myelopathy—cervical region
M47.22	Other spondylosis with radiculopathy—cervical region
M47.812	Cervical spondylosis without myelopathy or radiculopathy
M48.02	Spinal stenosis in cervical region
M50.0	Cervical disc disorder with myelopathy
M50.1	Cervical disc disorder with radiculopathy

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: In acquired cases, >50 yr
PREVALENCE: 1:1000 persons >65 yr old and 5:1000 persons >50 yr old
PREDOMINANT SEX AND AGE: Males and females affected equally; age depends on etiology (congenital vs. acquired); in acquired cases, most common between 20 and 65 yr of age

GENETICS: Genetic factors play a role in degenerative disease of the vertebrae and disc desiccation, but no one associated gene has been identified.
RISK FACTORS: Systemic diseases, rheumatoid arthritis, osteoarthritis; degenerative disc disease, repetitive microtrauma (spear tackler's spine), poor ergonomics

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Neurologic symptoms related to cervical stenosis may include:
  1. Chronic neck pain
  2. Unilateral or bilateral upper limb pain, often radiating
  3. Numbness of hands
  4. Arm or hand clumsiness
  5. Loss of hand dexterity
  6. Progressive loss of fine motor function of the hands
  7. Weakness of the upper extremities and proximal lower extremities
  8. Decreased sensation of the arm or hands
  9. Gait disturbances
  10. Hyperreflexia
- A positive Hoffman sign has somewhat low sensitivity but can be specific for cervical myelopathy in the context of other signs and symptoms.
- Central cord syndrome should be considered if a patient with existing cervical stenosis falls and develops weakness greater in the upper extremities than lower extremities.

ETIOLOGY

- Congenital or developmental cervical spinal stenosis is associated with skeletal hypoplasia resulting in diminished space within the spinal canal. Possible causes include:
  1. Vertebral segmentation failure
  2. Achondroplasia
  3. Incomplete vertebral arch fusion
  4. Anterior vertebral wedging or beaking
  5. Thoracolumbar kyphosis
  6. Early vertebral arch ossification
- Acquired stenosis accounts for the majority of cases; most arise from degenerative changes at the disk space level. It is a complex process that can also involve systemic, traumatic, and iatrogenic etiologies (Fig. E1). Several causes include:
  1. Facet joint and ligamentum flavum hypertrophy
  2. Stenosis from herniated disks
  3. Ossification of the posterior longitudinal ligament
  4. Spondylolisthesis
  5. Previous spinal fusions
  6. Paget disease
  7. Acromegaly
  8. Ankylosing spondylitis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ankylosing spondylitis
- Rheumatoid arthritis
- Diffuse idiopathic skeletal hyperostosis (DISH)
- Epidural, subdural, or intradural abscess
- Metabolic diseases (osteomalacia, vitamin B_{12}, or folate deficiency)
- Vascular disease (peripheral with claudication)
- Lumbar muscle strain
- Thoracic outlet syndrome
- Metastatic disease, Paget disease
- Conversion disorder, malingering
- Various intracranial processes

WORKUP

- Imaging modalities are of greatest utility in diagnosing cervical stenosis
  1. AP and lateral cervical spine x-rays
  2. Cervical spine CT scan can be helpful to describe the bony architecture
  3. Cervical spine MRI immediately if neurologic deficit or if pain >4 wk; most useful diagnostic test (Fig. E2)
  4. CT myelography if MRI is contraindicated (pacemaker)
- Consider nerve conduction studies if imaging equivocal

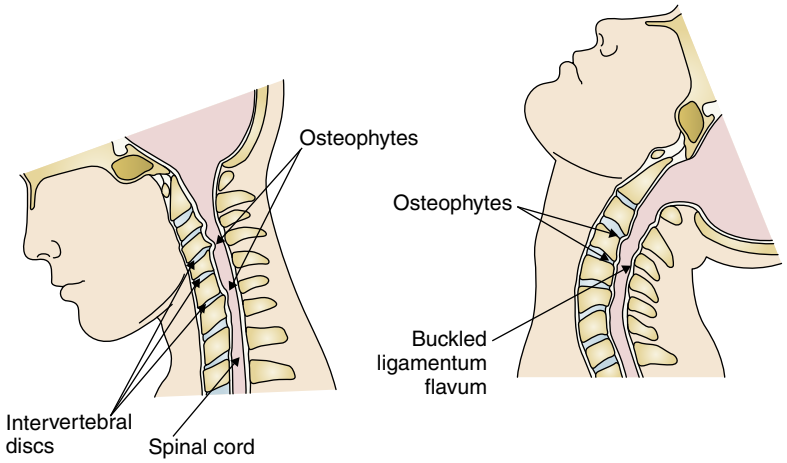

FIG. E1 Illustration of cervical spinal stenosis with associated causes (disc protrusion, osteophyte formation, hypertrophied ligamentum flavum). (From Frontera WR et al: *Essentials of physical medicine and rehabilitation*, Philadelphia, 2015, Elsevier.)

FIG. E2 T2 magnetic resonance image of the cervical spine demonstrating stenosis within the canal at the C4 to C5 and C5 to C6 level. (From Crowley P, Oxon BA: Neuroimaging of spinal canal stenosis, *MRI Clin N Am* 24:523-539, 2016.)

LABORATORY TESTS

Appropriate blood tests or CSF examination to rule out conditions on differential diagnosis

TREATMENT

Management of cervical spinal stenosis is geared toward symptom relief, preservation of function, and prevention of further neurologic decline. The decision between conservative or operative treatment depends on symptom severity, chronicity, and presence of neurologic deficits.

NONPHARMACOLOGIC THERAPY

- Physical/occupational therapy
- Mechanical measures (soft collar, heat, firm pillow) for pain relief
- Lifestyle changes
- Cervical traction

PHARMACOLOGIC THERAPY

- Analgesics
- Antiinflammatory agents:
  1. Use of PO or IV steroids
  2. Epidural steroid injections
- Antispasmodics
- Membrane stabilizing anticonvulsants (e.g., gabapentin) for neuropathic/radicular pain

DISPOSITION

- Nonoperative management of symptomatic patients is usually a temporizing measure; however, physicians must exhaust all nonsurgical options before referral for surgery in the absence of major neurologic deficits or progressive decline.
- Between 5% and 25% of patients with cervical stenosis will require surgery, with 33% of those experiencing favorable outcomes.
- Surgical intervention often involves decompression of the spinal cord/canal and fusion of the bony elements for stabilization. Laminoplasty, in which the spine is decompressed but the posterior processes are not resected, may be an option for eligible patients to retain motion.

REFERRAL

- Physical therapy
- Orthopedic or neurosurgical spine specialist for possible surgical decompression and fusion

PEARLS & CONSIDERATIONS

COMMENTS

As the population ages, cervical spinal stenosis will increase in prevalence. In general, treatment is initiated when the patient becomes symptomatic. The majority of patients can be treated conservatively, and in the primary care setting, immediate intervention for asymptomatic cervical stenosis is not necessary. However, any patient presenting with a neurologic deficit should be referred urgently to a spine specialist.

PREVENTION

Measures to strengthen neck musculature, improve the ergonomics of one's work environment, as well as avoiding chronic repetitive trauma may play a role in prevention of acquired cases.

PATIENT & FAMILY EDUCATION

Patient information on cervical spinal stenosis is available at www.spine-health.com/conditions/spinal-stenosis.

Spinal Stenosis, Lumbar

BASIC INFORMATION

DEFINITION

Lumbar spinal stenosis (LSS) is an anatomical impairment characterized by narrowing of the spinal canal or nerve root foramen (Fig. E1).

SYNONYMS

Central spinal stenosis
Lateral spinal stenosis
Spondylosis
Lumbar spinal stenosis
LSS

ICD-10CM CODE
M48.06 Spinal stenosis, lumbar region

EPIDEMIOLOGY & DEMOGRAPHICS

More common between 50 and 60 yr of age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms caused by direct mechanical compression or indirect vascular compression of the nerve roots or the cauda equina
- Neurogenic claudication: Leg, buttock, or back pain precipitated by walking and relieved by sitting
- Pain may radiate down to ankles and is associated with numbness, tingling, and weakness
- Taking a flexed posture reduces symptoms because it increases the available space in the lumbar spinal canal
- Decreased lumbar extension
- Normal peripheral pulses
- Positive Romberg sign (decreased proprioception)
- Wide-based gait
- Reduced knee and ankle reflex
- Urine incontinence

ETIOLOGY

Spinal stenosis may be primary or secondary.

- Primary stenosis (congenital or developmental narrowing):
  1. Idiopathic
  2. Achondroplasia
  3. Morquio-Ullrich syndrome
- Secondary stenosis (acquired):
  1. Degenerative (hypertrophy of the articular processes, disk degeneration, ligamentum flavum hypertrophy, spondylolisthesis)
  2. Fracture/trauma
  3. Postoperative (postlaminectomy)
  4. Paget disease
  5. Ankylosing spondylitis
  6. Tumors
  7. Acromegaly

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteoarthritis of the knee or hip
- Acute cauda equina syndrome, resulting from compression by epidural abscess or tumors
- Pain and weakness caused by multiple myeloma or osteomyelitis
- Intermittent claudication—peripheral vascular disease
- Peripheral neuropathy such as that caused by a herniated nucleus pulposus
- Scoliosis or spondylolisthesis
- Rheumatoid diseases: Ankylosing spondylitis, Reiter syndrome, fibromyalgia
- Box E1 summarizes the differential diagnosis for low back pain. Table E1 compares clinical features of spinal stenosis, peripheral vascular disease, and disk disease

WORKUP

History, physical examination (Fig. E2), and specific imaging studies. Historical clues to the cause of low back pain are summarized in Table E2. Fig. E3 illustrates an algorithm for the management of low back pain.

IMAGING STUDIES

- Lumbar spine film sensitivity 66%, specificity 93%.
- Ultrasound of the spinal canal has also been used.
- CT scan of the lumbosacral spine: Sensitivity (75% to 85%), specificity (80%).
- MRI of the lumbosacral spine (Fig. E4): Sensitivity (80% to 90%), specificity (95%).
- Myelogram: Sensitivity (77%), specificity (72%). Absolute stenosis is defined as the anterior-posterior (AP) diameter of the spinal canal <10 mm. Relative stenosis: 10 to 12 mm AP diameter.
- Electromyography (EMG) and nerve conduction velocity (NCV) are additional studies particularly useful in differentiating peripheral neuropathy from lumbar spinal stenosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Physiotherapy
- Lumbar corsets
- Back exercises
- Abdominal muscle strengthening
- Aquatic exercises

ACUTE GENERAL Rx

- Surgery should be considered in patients with significant compression of nerve roots as determined by MRI or CT and incapacitating symptoms limiting activities of daily living or bladder and bowel incontinence.
- Surgical procedures include decompressive laminectomy, arthrodesis, hemilaminectomy, and medial facetectomy.
- Lumbar interspinous process decompression using X-STOP device: A titanium oval spacer placed between the two adjacent spinous processes of the affected level; provides an unloading distractive force to the stenotic middle column part of the motion segment.
- There is little value in adding fusion to decompression surgery. For most patients, spinal stenosis surgery should be limited to decompression when no overt instability is present. Trials have shown that fusion for the treatment of spinal stenosis should be restricted to patients who have proven spinal

The X marks the ideal location to test for sensation for each nerve root. *C-SLR,* Crossed straight leg raise; *R-SLR,* reverse straight leg raise; *SLR,* straight leg raise. (From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, Saunders.)

instability, as confirmed on flexion-extension radiographs; vertebral destruction caused by trauma, tumors, infections, or spinal deformities, such as congenital spondylolisthesis or adult scoliosis.[1]

CHRONIC Rx

- Conservative therapy with NSAIDs (ibuprofen 800 mg PO tid, naproxen 500 mg PO bid) may be tried for symptomatic relief in addition to acetaminophen.
- Epidural glucocorticoid injections are widely used to treat symptoms of lumbar spinal stenosis; however, rigorous data are lacking regarding the effectiveness and safety of these injections. A recent trial revealed that in the treatment of lumbar spinal stenosis, epidural injection of glucocorticoids plus lidocaine offered minimal or no short-term benefit as compared with epidural injection of lidocaine alone.

DISPOSITION

- Approximately 20% of patients having surgery require repeat surgery within 10 yr. Nearly one third of these patients continue to experience pain.
- The natural history of spinal stenosis is one of slow progression. Although not very common, cord compression with resultant bowel and bladder incontinence and paresis can occur.
- Operative treatment in patients with LSS has been reported as being more effective in reducing pain and disability than nonoperative treatment. However, in a recent randomized trial comparing surgery vs. nonsurgical treatment of lumbar spinal stenosis, surgical decompression and a physical therapy regimen yielded similar effects among patients with LSS who were surgical candidates. Patients and health care providers should engage in shared decision-making conversations that include full disclosure of evidence involving surgical and nonsurgical treatments for LSS.[2]

TABLE E2 Historical Clues to the Cause of Low Back Pain

Questions for Patient	Potential Diagnosis
Does the back pain radiate down past the knees?	Radiculopathy and likely a herniated disk
Is the pain worse with walking and better with bending forward and sitting?	Spinal stenosis
Do you have morning back stiffness that improves with exercise?	Ankylosing spondylitis
Are you older than 50 yr?	Osteoporotic fracture, spinal malignancy
Has there been any recent history of blunt trauma?	Fracture
Do you take long-term corticosteroids?	Fracture, spinal infection
Do you have a history of cancer?	Spinal metastatic malignancy
Does your pain persist at rest?	Spinal malignancy, spinal infection
Has there been persistent pain for longer than 6 wk?	Spinal malignancy
Has there been unexplained weight loss?	Spinal malignancy
Is the pain worse at night?	Spinal malignancy, spinal infection
Are you immunocompromised (e.g., HIV infection, alcoholism, diabetes)?	Spinal infection
Have you had fevers or chills?	Spinal infection
Do you have pain, weakness, or numbness in both legs?	Cauda equina syndrome
Do you have bladder or bowel control problems?	Cauda equina syndrome

HIV, Human immunodeficiency virus.
From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, Saunders.

REFERRAL

- Patients who have spinal stenosis should be referred to an orthopedic surgeon specializing in back surgery or to a neurosurgeon.
- Pain clinic referrals should be made if surgery is contraindicated or if the patient does not want surgery.

PEARLS & CONSIDERATIONS

COMMENTS

- Approximately one third of patients have coexisting peripheral vascular disease.
- The severity of cauda equina constriction is directly related to the walking ability and the pain intensity in the legs and back.
- Spinal stenosis is also a cause of chronic low back pain in the young.

BASIC INFORMATION

DEFINITION

The spinocerebellar ataxias (SCAs) are a heterogeneous group of autosomal-dominant inherited genetic conditions that cause progressive ataxia and other neurologic symptoms.

SYNONYMS

Autosomal-dominant cerebellar ataxia (ADCA)
Machado-Joseph disease (eponym for SCA3; this may be the most common SCA)

ICD-10CM CODES
G11.8 Other hereditary ataxias
G11.9 Hereditary ataxia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The prevalence of the condition is approximately 3 persons per 100,000. The most common SCAs are 1, 2, 3, 6, and 7.
PREDOMINANT SEX: SCA demonstrates no gender preference.
PREDOMINANT AGE: The age of onset is often during the 30s or 40s. However, this can be highly variable, even within family groups; SCAs can occur anytime from childhood to late adulthood.
GENETICS: All SCAs are inherited in an autosomal dominant fashion; however, reduced penetrance can be present.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Chronically progressive cerebellar ataxia is the predominant symptom of all of the SCAs. It typically presents as a combination of balance and gait difficulty, limb incoordination, nystagmus, and dysarthria.
- More than 36 different genetic subtypes of SCA have been described to date. Although certain clinical characteristics are common to specific SCA subtypes, these conditions have significant overlap and variability; therefore, making a diagnosis based on the clinical presentation alone can be challenging and sometimes impossible without genetic testing. The more common SCAs may include the following distinguishing features in addition to ataxia:
  1. SCA1 can be characterized by nystagmus, spasticity, and neuropathy.
  2. SCA2 can be characterized by slow saccades, gaze palsy, neuropathy, and sometimes parkinsonism or dementia.
  3. SCA3, also known as Machado-Joseph disease (Fig. E1), can be characterized by neuropathy, amyotrophy, parkinsonism, and dystonia.
  4. SCA6 is generally felt to be a pure cerebellar syndrome with ataxia and nystagmus (gaze evoked and downbeat) as well as having a frequently later age of onset.
  5. SCA7 is characterized by dementia, vision loss caused by a pigmentary maculopathy, and spasticity.
  6. Knowledge in this area is constantly expanding and being updated. Online sources of information (e.g., Online Mendelian Inheritance in Man [http://www.ncbi.nlm.nih.gov/omim]) can be invaluable for tracking new developments.

ETIOLOGY

Several of the SCAs are the result of polyglutamine CAG repeat expansions; this leads to the accumulation of mutant proteins inside neurons, which is thought to cause neuronal dysfunction and cell death. Higher numbers of repeats are correlated with an earlier onset of symptoms, and anticipation in subsequent generations may be present. Other types of repeat expansions and point mutations have been found with several SCAs; for others, the affected gene has not been identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Structural cerebellar abnormality: Includes cerebellar tumor, inflammation (e.g., multiple sclerosis), stroke, or hemorrhage; the time course for these causes is typically more acute or subacute than chronic.
- Endocrine dysfunction: Hypothyroidism or hypoparathyroidism can uncommonly cause ataxia.
- Alcoholic cerebellar degeneration: Caused by heavy alcohol use; gait ataxia predominates.
- Other toxin-induced ataxias: Antiepileptic medications, lithium, heavy metals (lead, manganese, mercury, bismuth), and chemotherapeutic agents.
- Creutzfeldt-Jakob disease: Rapidly progressive ataxia, dementia, and myoclonus.
- Paraneoplastic cerebellar degeneration: Found in association with primary malignancies (e.g., small cell lung cancer, breast cancer); subacute-onset ataxia that progresses rapidly.
- Celiac disease: Gluten-sensitive enteropathy with malabsorption may be associated with ataxia; autoantibodies such as antigliadin, antitissue transglutaminase (TTG), and/or IgA endomysial antibodies are typically present.
- Antiglutamic acid decarboxylase (GAD) antibody-associated cerebellar ataxia: A rare autoimmune cause of late-onset ataxia that may be partially responsive to immunotherapy.
- Multiple system atrophy (MSA): The cerebellar variant of this disorder causes ataxia; there is typically associated parkinsonism with some degree of autonomic dysfunction (e.g., orthostatic hypotension, urinary incontinence); brain MRI may reveal pontocerebellar atrophy.
- Friedreich ataxia: Autosomal recessive inheritance, generally younger age of onset (i.e., mean 15 yr of age), lower limb areflexia, and posterior column dysfunction.
- Ataxia associated with vitamin E deficiency: Can be an autosomal recessive disorder or acquired; clinically resembles Friedreich ataxia, with areflexia and loss of position sense.
- Ataxia telangiectasia: Autosomal recessive inheritance, childhood onset, oculocutaneous telangiectasias, and immunodeficiency.
- Wilson disease: Can cause hepatic dysfunction, psychiatric symptoms, and a variety of movement disorders, including ataxia; particularly important to screen for this in patients who are young at onset because it is treatable.
- Dentatorubral-pallidoluysian atrophy (DRPLA): Autosomal dominant like SCA but typically has ataxia with associated choreoathetosis, myoclonus, epilepsy, and dementia; frequently grouped with the SCAs due to its shared pathogenic CAG repeat expansion.
- Fragile X–associated tremor/ataxia syndrome: Premutation of the fragile X mutation gene; more common among males than females; late onset of ataxia (i.e., >50 yr),

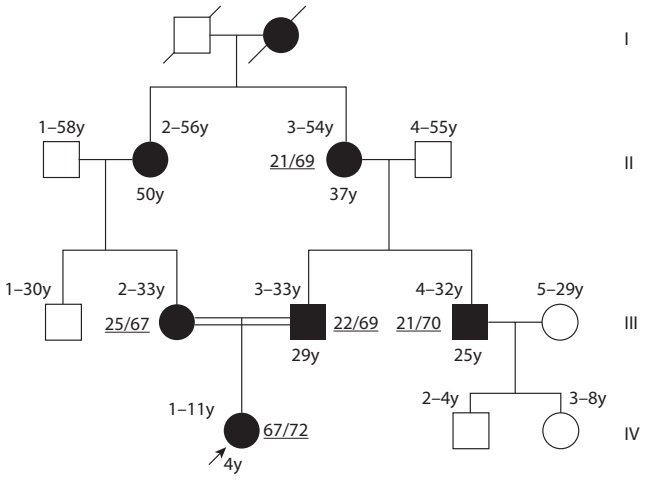

FIG. E1 Family pedigree of proband (IV-1). Age at onset of spinocerebellar ataxia type 3 symptoms is given beneath symbols (*italics*). Above the symbols, the actual age of the members of the family is given. If tested, the number of CAG repeat units of the *ATXN3* allele pair is also given (*underscored italics*). (From Daniel RC et al: Homozygosity enhances severity in spinocerebellar ataxia type 3, *Pediatri Neurol* 38[4]:296-299, 2008.)

tremor, and sometimes parkinsonism; MRI often shows T2 hyperintensities in the middle cerebellar peduncle.
- Episodic ataxias: Autosomal dominant, transient ataxia lasting seconds to days depending on the mutation; pediatric onset in most; ataxia may be responsive to acetazolamide.
- Spastic ataxias: Distinguished by prominent, symmetric spasticity, particularly of the lower extremities. Most of these conditions have an autosomal recessive pattern of inheritance and include autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS), hereditary spastic paraplegia (HSP), and cerebrotendinous xanthomatosis.
- Box E1 shows the classification of the various causes of ataxia.

LABORATORY TESTS

- Rule out acquired causes of ataxia, depending on the clinical scenario, with thyroid studies, toxicology screening, and the determination of the vitamin E level or presence of paraneoplastic antibodies.
- For pediatric patients, screen for ataxia telangiectasia with serum alpha-fetoprotein (AFP).
- Screen for Wilson disease with ceruloplasmin and, if indicated, a 24-hour urinary copper determination.
- Genetic testing is commercially available for many but not all of the SCAs (SCA 1, 2, 3, 5, 6, 7, 8, 10, 12, 13, 14, 17, 28, DRPLA).

IMAGING STUDIES

- MRI of the brain should be performed to exclude structural abnormalities.
- Cerebellar or brain stem atrophy can be seen with several of the SCA subtypes.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Speech therapy for dysarthria and dysphagia
- Physical therapy
- Occupational therapy

CHRONIC Rx

Treatment is symptomatic and supportive. In some cases, parkinsonism can respond to levodopa. Clonazepam can be helpful if tremor is prominent. Spasticity can be treated with baclofen or tizanidine. Focal spasticity or dystonia may benefit from botulinum toxin injections.

DISPOSITION

All SCA disorders are progressive, although the speed is variable from subtype to subtype and from patient to patient. On average, patients become wheelchair bound 15 yr after the onset of ataxia, and death can occur after 20 to 25 yr.

REFERRAL

Referral to a general neurologist or to a movement disorders center is appropriate.

PEARLS & CONSIDERATIONS

COMMENTS

- Genetic testing can have consequences for both the patient and the family. These issues should be discussed during the informed consent process. Patients who desire asymptomatic testing as a result of a relevant family history should undergo genetic counseling before testing.
- In symptomatic patients with a family history of dominantly inherited ataxia, the diagnostic process is relatively straightforward. Genetic testing that is directed toward likely mutations by phenotype and ethnic origin should be the first step, rather than an extensive workup for other causes.

BOX E1 Classification of Ataxia

Congenital Ataxias

Hereditary Ataxias

Autosomal Recessive Ataxias
- Friedreich ataxia
- Ataxia–telangiectasia
- Ataxia with oculomotor apraxia type 1
- Ataxia with oculomotor apraxia type 2
- Autosomal recessive spastic ataxia of Charlevoix-Saguenay
- Abetalipoproteinemia
- Ataxia with isolated vitamin E deficiency
- Refsum disease
- Cerebrotendinous xanthomatosis
- Marinesco-Sjögren syndrome
- Autosomal recessive ataxia with known gene locus
- Early-onset cerebellar ataxia

X-Linked Ataxias
- Fragile X tremor ataxia syndrome

Autosomal Dominant Ataxias
- Spinocerebellar ataxias
- Dentatorubral-pallidoluysian atrophy
- Episodic ataxias

Nonhereditary Degenerative Ataxias
- Multiple system atrophy, cerebellar type
- Sporadic adult-onset ataxia of unknown etiology

Acquired Ataxias
- Alcoholic cerebellar degeneration
- Ataxia as a result of other toxic causes (e.g., antiepileptic medications, lithium, solvents)
- Paraneoplastic cerebellar degeneration (e.g., anti-Hu, anti-VGKC, anti-CV2)
- Other immune-mediated ataxias (e.g., gluten ataxia, ataxia associated with anti-glutamic acid decarboxylase antibodies)
- Acquired vitamin E deficiency
- Hypothyroidism
- Ataxia as a result of physical causes (e.g., heat stroke, hyperthermia)

From Goetz CG: *Textbook of clinical neurology*, ed 3, Philadelphia, 2007, WB Saunders.

BASIC INFORMATION

DEFINITION

Spondyloarthropathies (SpAs) are a group of interrelated systemic autoinflammatory conditions that are serologically negative for rheumatoid factor, connected by an underlying genetic risk with similar patterns of inflammation. This group encompasses ankylosing spondylitis, psoriatic arthritis, reactive arthritis, enteropathic arthritis, and undifferentiated spondyloarthritis (Table 1). SpAs are broadly classified by axial versus peripheral joint involvement, with or without radiographic progression.

SYNONYMS

Spondyloarthritis
Spondylopathy
Spondylitis
Spondylosis
SPAs

ICD-10CM Codes

M46.80	Other specified inflammatory spondylopathies, unspecified site
M46.82	Other specified inflammatory spondylopathies, cervical region
M46.83	Other specified inflammatory spondylopathies, cervicothoracic region
M46.86	Other specified inflammatory spondylopathies, lumbar region
M46.87	Other specified inflammatory spondylopathies, lumbosacral region
M46.89	Other specified inflammatory spondylopathies, multiple sites
M46.81	Other specified inflammatory spondylopathies, occipito-atlantoaxial region
M46.88	Other specified inflammatory spondylopathies, sacrococcygeal region
M46.84	Other specified inflammatory spondylopathies, thoracic region
M46.85	Other specified inflammatory spondylopathies, thoracolumbar region

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Worldwide prevalence of SpA is 0.2% to 1.6%, with over 1% of the U.S. population affected. Varies regionally with prevalence of HLA-B27.

PREDOMINANT SEX AND AGE: Males younger than age 45 yr are predominantly affected. Previously, male:female ratio was thought to be 10:1; more recently, about 3:1.

Patients older than 45 yr may present with chronic, severe disease due to diagnostic delays.

GENETICS: Association with the *HLA-B27* allele is the strongest known genetic risk factor.

RISK FACTORS: *HLA-B27* allele*, male sex*, smoking*, ethnic background, family history of SpA, and certain infections (*Associated with more severe disease)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History:
  1. Inflammatory low back pain may be the primary presenting symptom:
     a. Pain and stiffness in low back or buttocks that is worst in the morning, may awaken the patient from sleep, and improves with exercise
     b. Morning stiffness generally lasting longer than 1 hour
     c. Improvement with NSAIDs
     d. Sensitivity up to 90% and positive likelihood ratio up to 2.2 for axial SpA
  2. Symptoms of systemic and peripheral inflammation are additional clues that can be elicited in a comprehensive review of systems:
     a. Uveitis: Painful ocular inflammation
     b. Psoriasis: Chronic skin inflammation with red patches and silvery scales
     c. Inflammatory bowel disease: Crohn disease and ulcerative colitis
     d. Synovitis: Inflammation of the synovial membrane of joints
     e. Enthesitis: Inflammation at the site of tendon or ligament insertion onto bone
     f. Dactylitis: Tenosynovitis of the digits causing classic sausage-like appearance
- Physical exam:
  1. Axial joints: Spine and sacroiliac (SI) joints
  2. Inspect curvature, palpate for tenderness, and evaluate range of motion for cervical, thoracic, and lumbar spine. Measure degree of axial involvement with occiput wall, thoracic expansion. Patients with SpA may have an abnormal Schober test result (Fig. E1). This test is performed by having the patient stand erect and marking the distance between the midpoint of the posterior superior iliac spines ("dimples of Venus") and 10 cm above that point. The patient is then asked to maximally flex forward while the more caudal spot is kept stationary. The more cephalad point on the tape measure should demonstrate at least 5 cm of excursion. This abnormality also can be seen with lumbar degenerative disk disease. Test for sacroiliitis with Patrick and Gaenslen tests
  3. Peripheral joints: Lower extremity predominance
  4. Inspect for signs of inflammation, including dactylitis, synovitis, and enthesitis
  5. Evaluate for systemic involvement manifesting as anterior uveitis and psoriasis:
     a. Slit lamp is necessary to diagnose anterior uveitis
     b. Full skin exam is critical to detect occult psoriasis; look for nail changes
- Musculoskeletal manifestations commonly affect weight-bearing joints with high mechanical stress; thus, it is particularly important to examine the lumbar spine, SI joints, and lower extremities
- Degree of axial involvement can be measured via specialized exam techniques, which are used to track disease activity and response to treatment over time

ETIOLOGY

- Genetic:
  1. The *HLA-B27* allele has a strong association with SpA, through mechanisms not fully understood.
- Environmental:
  1. Microbial infections, disruptions in barrier defense mechanisms (skin and intestinal mucosa), and mechanical articular stressors may trigger an inflammatory response, which then develops into signs and symptoms specific to each type of SpA.
- Autoinflammatory:
  1. Key components of the inflammatory cascade involved in the pathogenesis of SpA are TNF, IL-12, IL-17, IL-23, and prostaglandins. Success in treatment with targeted therapies to each of these molecules has helped us understand their role in the etiology of SpA.

TABLE 1 Comparison of Ankylosing Spondylitis and Related Disorders

Feature	Ankylosing Spondylitis	Psoriatic Arthritis	Reactive Arthritis	Enteropathic Arthropathy
Sex (male:female)	2-3:1	1:1	1:1	1:1
Age of onset	<40 yr	35-55 yr	20-40 yr	Any age
Sacroiliitis or spondylitis (%)	100	~20	~40	<20
Symmetry of sacroiliitis	Symmetrical	Asymmetrical	Asymmetrical	Symmetrical
Peripheral arthritis (%)	~25	95	90	5-20
Distribution	Axial and lower limbs	Variable	Lower limbs	Variable
HLA-B27 positivity (%)	85-95	25-60*	30-70	7-70†
Uveitis	0-40	~20	~50	<15

TABLE 2 Criteria for Spondyloarthritis (SpA)*

Amor Criteria	ESSG Criteria
A. Past or current clinical manifestations:	Inflammatory back pain *or* synovitis
1. Back pain at night and/or back stiffness in the morning (1 point)	• Asymmetric synovitis or • Predominantly lower limb synovitis
2. Asymmetric oligoarthritis (2 points)	AND
3. Gluteal pain without other details (1 point) or alternating gluteal pain (2 points)	One or more of the following: • Positive family history • Psoriasis
4. Sausage-like digit or toe (2 points)	• Inflammatory bowel disease
5. Heel pain or other enthesopathy (2 points)	• Urethritis, cervicitis, or acute diarrhea within 1 mo before arthritis
6. Iritis (2 points)	• Buttock pain alternating between right and left gluteal areas
7. Nongonococcal urethritis within 1 mo before the onset of arthritis (1 point)	• Enthesopathy • Sacroiliitis (radiography)
8. Acute diarrhea within 1 mo before the onset of arthritis (1 point)	
9. Past or current psoriasis and/or balanitis and/or inflammatory bowel disease (2 points)	
B. Radiographic changes:	
10. Sacroiliitis grade 2 or more if bilateral, grade 3 or more if unilateral (3 points)	
C. Predisposing genetic factors:	
11. Presence of HLA-B27 antigen and/or family history of ankylosing spondylitis, Reiter syndrome, psoriasis, uveitis, or chronic bowel disease (2 points)	
D. Responsiveness to treatment:	
12. Improvement within 48 hours after initiation of an NSAID and/or recurrence within 48 hours after discontinuation of a nonsteroidal antiinflammatory drug (2 points)	

*Definite SpA if ≥6 points; probable SpA if 5 points.
ESSG, European Spondyloarthropathy Study Group; *NSAID,* nonsteroidal antiinflammatory drug.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

Dx DIAGNOSIS

Table 2 summarizes diagnostic criteria for SpA.

DIFFERENTIAL DIAGNOSIS

- Seronegative rheumatoid arthritis (peripheral presentation)
- Degenerative disc disease (axial presentation) or DISH
- Inflammatory osteoarthritis (axial or peripheral presentation)
- Hypertrophic osteoarthropathy (peripheral presentation)

WORKUP

- Young patients, particularly men younger than 45 yr, with chronic inflammatory low back pain responsive to NSAIDs should be screened.
- Patients with psoriasis, inflammatory bowel disease, or recent gastrointestinal or genitourinary infections presenting with new-onset low back or peripheral joint pain should also be screened.
- Screening begins with a comprehensive history and physical exam.
- HLA-B27 testing and imaging of SI joints and/or lumbar spine are indicated based on clinical suspicion.

LABORATORY TESTS

- HLA-B27:
  1. Negative test does not rule out SpA.
  2. Sensitivity: 95% for ankylosing spondylitis, 80% for reactive arthritis, 70% for psoriatic arthritis, and 50% for enteropathic arthritis
- Elevated ESR and CRP, anemia of chronic disease, leukocytosis, and thrombocytosis may reflect active inflammation. A normal CRP or ESR does not rule out spondyloarthropathies
- Testing for rheumatoid arthritis antibodies is generally negative (RF, CCP)
- Synovial fluid is inflammatory and nonspecific, with WBC >2,000/mm^2

IMAGING STUDIES

- **X-Ray:** SI joints and lumbar spine:
  1. May not detect early inflammation
  2. 20% to 80% have non-radiographic disease at time of presentation
  3. May show signs of structural damage such as erosions, syndesmophytes, sclerosis, and ankylosis in chronic axial disease
- **MRI:** SI joints and lumbar spine:
  1. Subchondral bone marrow edema in early disease
  2. Useful when x-ray and clinical findings are nondiagnostic but clinician's suspicion for axial SpA remains high

Rx TREATMENT

Improvement in symptoms, preservation of function, and prevention of structural damage can be achieved through a multidisciplinary approach.

NONPHARMACOLOGIC THERAPY

- Physical and occupational therapies improve functional outcomes
- Surgery:
  1. Joint replacements (high-impact joints such as hips)
  2. Spinal wedge osteotomy (advanced axial disease)
  3. Colectomy (advanced enteropathic arthritis)

ACUTE GENERAL Rx

- NSAIDs are first line.
- Avoid steroids in psoriatic arthritis due to risk of life-threatening pustular psoriasis and erythroderma.

CHRONIC Rx

- **NSAIDs:**
  1. Up to 35% of patients may achieve remission
  2. Best response in early disease
  3. Continuous dosing may prevent radiographic progression of axial disease
- **DMARDs:** Effective for peripheral involvement only, not effective in axial disease
  1. Methotrexate, leflunomide, sulfasalazine
- **TNF inhibitors:** NSAID or DMARD failure
  1. Infliximab, adalimumab, golimumab, etanercept, certolizumab pegol
- **IL-17 and IL-12/23 inhibitors:** 2nd TNF inhibitor failure
  1. Recent studies show similar efficacy compared to TNF inhibitors
  2. Ixekizumab (IL-17 inhibitor) recently approved for ankylosing spondylitis
  3. Ustekinumab (IL-12/23 inhibitor) and secukinumab (IL-17 inhibitor) are effective in psoriatic arthritis. Secukinumab also is approved for ankylosing spondylitis

4. Ustekinumab is also effective in Crohn-enteropathic arthritis

- **JAK inhibitors:** Phase II clinical trial
  Tofacitinib (JAK 1, 2, 3 inhibitor) was shown to improve clinical and imaging outcomes in axial SpA, with phase III trial data pending.
  1. Tofacitinib is approved to treat both UC and psoriatic arthritis.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Strong clinical trials are lacking.
- Small studies have shown Pilates, tai chi, deep tissue massage, and hydroelectric therapy can be beneficial in axial SpA.

DISPOSITION

- Function and mobility may be limited in advanced axial disease.
- Psoriatic arthritis is an independent risk factor for cardiovascular disease.

REFERRAL

Rheumatology, dermatology, ophthalmology, gastroenterology, infectious disease

PEARLS & CONSIDERATIONS

COMMENTS

Young patients with chronic inflammatory low back pain deserve referral to a rheumatologist. HLA-B27 positivity is not required for diagnosis if strong clinical features are present. MRI may be needed to detect early axial disease. Repeated spinal x-rays at scheduled intervals (e.g. every 2 yr) are not recommended in patients with active or stable non-radiographic axial SpA. Track axial disease activity with clinical scoring systems and physical exam measurements. Traditional DMARDs are not effective in axial disease.

PREVENTION

High index of suspicion and prompt referral allows for early diagnosis. Early treatment with treat-to-target approach may prevent symptomatic and radiographic progression.

PATIENT & FAMILY EDUCATION

Smoking cessation is key. Discuss with family the implications of strong genetic component. Educate patients with psoriasis and inflammatory bowel disease about symptoms of inflammatory low back or peripheral joint pain to monitor for development of SpA in these high-risk individuals.

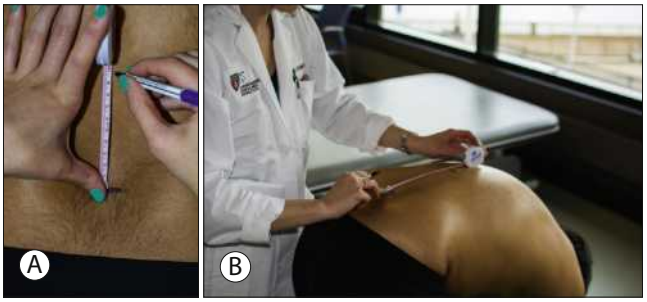

FIG. E1 Schober test. A, With the patient standing, measure 10 cm superior from the midpoint of the posterior superior iliac spines. **B,** The patient then is asked to maximally flex forward while the more caudal spot is kept stationary. The total length between the lines should be greater than 15 cm. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

BASIC INFORMATION

DEFINITION

Spontaneous abortion is fetal loss before wk 20 of pregnancy, calculated from the patient's last menstrual period, or the delivery of a fetus weighing <500 g. Early loss is before menstrual wk 12, whereas late loss refers to losses from wks 12 to 20.

Spontaneous abortion can also be classified as incomplete (partial passage of fetal tissue through partially dilated cervix), complete (spontaneous passage of all fetal tissue), threatened (uterine bleeding without cervical dilation or passage of tissue), inevitable (bleeding with cervical dilation without passage of fetal tissue), or missed abortion (intrauterine fetal demise without passage of tissue).

Recurrent spontaneous abortion involves three or more spontaneous pregnancy losses before wk 20. It affects approximately 1% of couples attempting to conceive. However, in actual practice, most reproductive experts consider two spontaneous pregnancy losses sufficient to initiate an evaluation for habitual or recurrent spontaneous abortion, since the risk of another loss is similar at this point, and the emotional stress is high. As many as 5% of couples and probably even a higher proportion of couples in which the woman is over the age of 35 are affected by two or more consecutive spontaneous abortions.

SYNONYMS

Spontaneous miscarriage
Miscarriage
Spontaneous pregnancy loss

ICD-10CM CODES

O03.89	Complete or unspecified spontaneous abortion with other complications
O03.9	Complete or unspecified spontaneous abortion without complication

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 10% to 20% of clinically recognized pregnancies; 80% of miscarriages occur in the first trimester. Recurrent miscarriage occurs in <1% of couples attempting to have children.

GENETICS:

- Fetal chromosomal aneuploidy and polyploidy account for the overwhelming majority of first-trimester losses.
- Autosomal trisomy accounts for the majority of abnormalities, followed by monosomy X, tetraploidy, and, lastly, structural chromosomal abnormalities.
- The incidence of trisomy increases as maternal age increases.

MATERNAL CAUSES:

- Uterine anomalies: Müllerian abnormalities such as unicornuate, bicornuate, or septated uterus are associated with increased miscarriage risk, although rates vary in different studies. A septated uterus is most highly associated with recurrent loss and can be surgically corrected and thus is important to diagnose. Other intrauterine pathologies such as synechiae, leiomyomas, or prior DES exposure are important to rule out also.
- Incompetent cervix (iatrogenic or congenital, associated with 20% of mid-trimester losses).
- Antiphospholipid antibody syndrome.
- Uncontrolled diabetes mellitus.
- Rare or controversial causes include HLA associations between mother and father; infections such as tuberculosis, *Chlamydia,* and *Ureaplasma;* smoking and alcohol use; irradiation; progesterone deficiency; and environmental toxins. Most of the literature is observational in nature, which may skew risk factor data.
- With two or more spontaneous miscarriages, a karyotype can be performed on the products of conception to evaluate for aneuploidy, which may be associated with a balanced translocation in one of the parents, and which has a substantially increased risk for abortion (depending on the actual type of translocation); if the pregnancy is carried to term, it has a 3% to 5% risk for an unbalanced karyotype. In patients with habitual abortion, evaluation for anatomic defects such as uterine septum and for antiphospholipid syndrome (lupus anticoagulant, beta 2 glycoprotein IgG/IgM, and anticardiolipin antibody IgG/IgM) should also be obtained.

RISK FACTORS:

- Vaginal bleeding, especially >3 d, carries with it a 15% to 20% chance of miscarriage
- Advancing maternal age
- Two or more prior miscarriages
- Significant underlying maternal health issues such as uncontrolled diabetes, thyroid disease, or other endocrine disturbances
- Illicit substance use
- Obesity
- Alcohol, smoking, and excessive caffeine intake
- Use of fluconazole in pregnancy is associated with a statistically significant increased risk of spontaneous miscarriage

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Profuse bleeding and cramping have a higher association with miscarriage than bleeding without cramping, which is more consistent with a threatened miscarriage.
- Cervical dilation with history or finding of fetal tissue at cervical os may be present.
- In cases of missed abortion, uterine size may be smaller than menstrual dating, in contrast to molar gestation, where size may be greater than dates.
- The presence of nausea and vomiting in early pregnancy is associated with a reduced risk for pregnancy loss.

ETIOLOGY

In a general overview, the etiology can be classified in terms of maternal (environmental) and fetal (genetic) factors, with the majority of miscarriages being related to genetic or chromosomal causes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Normal pregnancy
- Hydatidiform molar gestation
- Ectopic pregnancy
- Dysfunctional uterine bleeding
- Pathologic endometrial or cervical lesions

WORKUP

- All patients with bleeding in the first trimester should have an evaluation for possible ectopic pregnancy.
- If there are three early, prior pregnancy losses, a workup and treatment for recurrent miscarriage should begin before next conception. If there is a strong history for second-trimester loss, consideration for cerclage should be given if the history is consistent with incompetent cervix (e.g., painless cervical dilation).
- Most providers will initiate an evaluation for couples who have had two previous losses.
- One unexplained fetal loss beyond 10 wk or 1 birth before 34 wk because of preeclampsia should prompt an evaluation for antiphospholipid antibody syndrome.

LABORATORY TESTS

- Type and antibody screen are used to evaluate the need for Rh immune globulin.
- Recurrent pregnancy loss: During the preconception period in patients with recurrent pregnancy loss, hemoglobin A_{1c}, TSH, prolactin, anticardiolipin antibody, lupus anticoagulant, 20210A beta 2 glycoprotein antibodies, karyotyping, and anatomic evaluation with hysterosalpingography, or saline ultrasonography to assess for uterine septum. With increasing age, oocyte quality is a factor, and some practitioners will perform day 3 of the menstrual cycle FSH and antimüllerian hormone to assess for diminished ovarian reserve. Progesterone level <5 mg/dl suggests nonviable gestation vs. >25 mg/dl, which suggests a good prognosis.

IMAGING STUDIES

Transvaginal sonogram (preferred) (Figs. 1 through 3) can be used with menstrual dating and serum quantitative human chorionic gonadotropin to document pregnancy location, fetal heart presence, gestational sac size, and adnexal pathology.

TREATMENT

NONPHARMACOLOGIC THERAPY

Depending on the patient's clinical status, desire to continue the pregnancy, and certainty of the diagnosis, expectant management can be considered. In pregnancies <6 wk or >14 wk, complete expulsion of fetal tissue usually occurs, and surgical intervention such as D&C can be avoided.

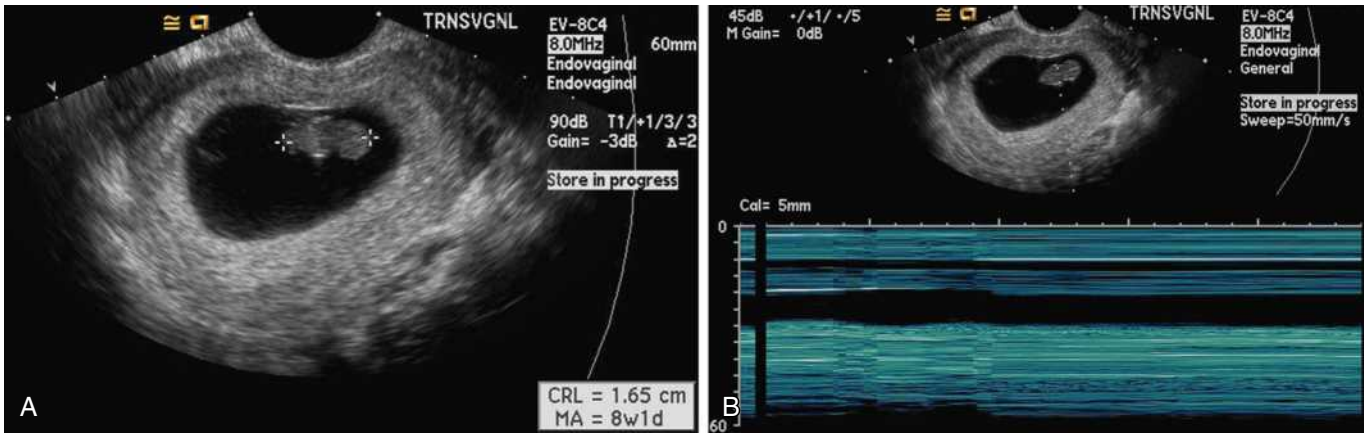

FIG. 1 Embryonic demise. Transvaginal **(A)** and M-mode **(B)** ultrasound. There was no cardiac activity in an embryo measuring more than the threshold of 5 mm. (From Fielding JR et al: *Gynecologic imaging*, Philadelphia, 2011, WB Saunders.)

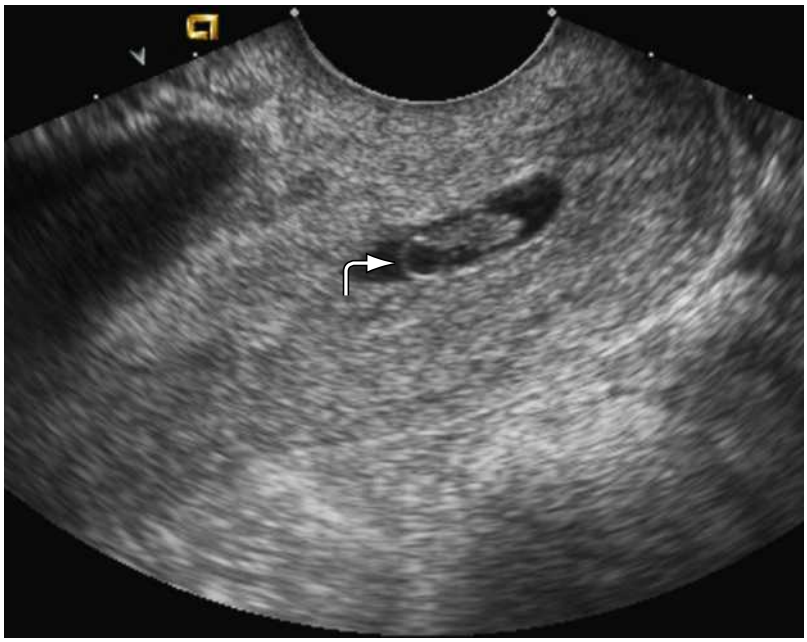

FIG. 2 Inevitable abortion. Transvaginal ultrasonography shows a sac in the cervical canal, past the internal os. The embryo *(curved arrow)* was nonviable. (From Fielding JR et al: *Gynecologic imaging*, Philadelphia, 2011, WB Saunders.)

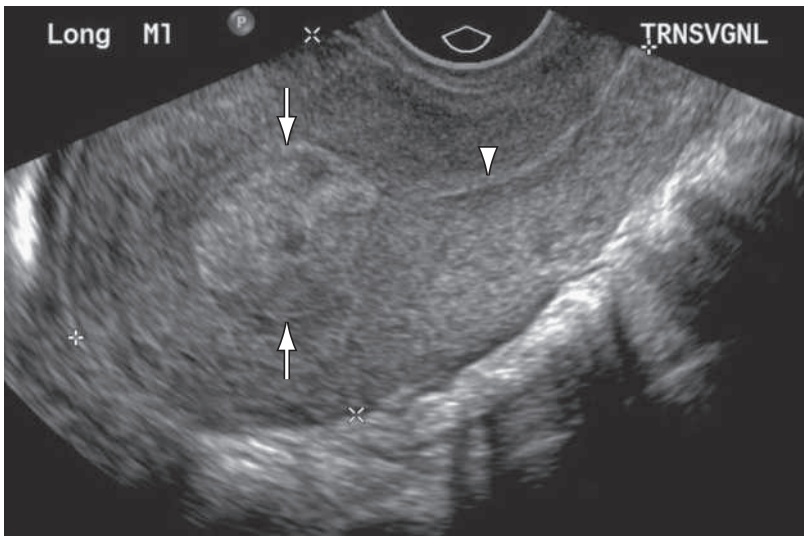

FIG. 3 Incomplete abortion. Transvaginal ultrasonography shows an echogenic mass *(arrows)* in the fundal endometrial cavity. The lower-segment endometrium *(arrowhead)* is normal. (From Fielding JR et al: *Gynecologic imaging*, Philadelphia, 2011, WB Saunders.)

ACUTE GENERAL Rx

- Incomplete miscarriage between 6 and 14 wk can be associated with great blood loss; these patients should undergo D&C.
- In cases of missed abortion, if fetal demise has occurred >6 wk before or gestational age is >14 wk, there is an increased risk of hypofibrinogenemia with disseminated intravascular coagulation. Thus D&C or manual vacuum aspiration should be performed early in the disease course. Consider use of misoprostol (Cytotec) in appropriate cases where the patient wishes to avoid surgery.
- There is evidence that a surgical approach leads to quicker resolution of the pregnancy event with fewer visits being required.
- Rh-negative patients should be given RhoGAM 50 mcg IM to prevent Rh isoimmunization.

PEARLS & CONSIDERATIONS

Spontaneous pregnancy loss is recommended as a replacement for the term *abortion* and to acknowledge the emotional aspects of losing a pregnancy.

BASIC INFORMATION

DEFINITION

Spontaneous bacterial peritonitis (SBP) is an inflammatory reaction of the peritoneum secondary to the presence of bacteria or other microorganisms. More specifically, SBP is defined as an ascitic fluid infection without an evident intraabdominal surgically treatable source occurring primarily in patients with advanced cirrhosis of the liver.

SYNONYMS

Primary peritonitis
SBP
Peritonitis, spontaneous bacterial

ICD-10CM CODE
K65.2 Spontaneous bacterial peritonitis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The prevalence of SBP in cirrhotic patients admitted to the hospital has been estimated at 10% to 30%.
PREDOMINANT SEX: Males are affected more often than females.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute fever with accompanying abdominal pain/ascites, nausea, vomiting, diarrhea.
- In cirrhotic patients, presentation may be subtle with a low-grade temperature (100° F; 37.8° C) with or without abdominal abnormalities.
- In patients with ascites, a heightened degree of awareness is necessary for detection.
- Jaundice and encephalopathy.
- Deterioration of mental status and/or renal function.
- Table 1 summarizes symptoms and signs of ascetic fluid infection.

ETIOLOGY

- *Escherichia coli*
- *Klebsiella pneumoniae*
- *Streptococcus pneumoniae*
- *Streptococcus* and *Enterococcus* spp.
- *Staphylococcus aureus*
- Anaerobic pathogens: *Bacteroides, Clostridium* organisms
- Other: Fungal, mycobacterial, viral

DIAGNOSIS

The diagnosis of SBP is established by a positive ascitic fluid bacterial culture and an elevated ascitic fluid absolute polymorphonuclear leukocyte count (≥250 cells/mm^3).

DIFFERENTIAL DIAGNOSIS

- Appendicitis (in children)
- Perforated peptic ulcer
- Secondary bacterial peritonitis
- Peritoneal abscess
- Splenic, hepatic, or pancreatic abscess
- Cholecystitis
- Cholangitis

WORKUP

Paracentesis and ascitic fluid analysis will confirm diagnosis (see "Laboratory Tests").

LABORATORY TESTS

Ascitic fluid analysis reveals the following:

- Cell count with an absolute polymorphonuclear cell count >250/mm^3
- Presence of bacteria on Gram stain
- pH <7.31
- Lactic acid >32 mg/dl
- Protein <1 g/dl
- Glucose >50 mg/dl
- Lactate dehydrogenase <225 μU/ml
- Positive culture of peritoneal fluid
- Measurement of the serum/ascites/albumin gradient: The serum/ascites/albumin gradient indirectly measures portal pressure. The albumin concentration of ascitic fluid and serum must be obtained on the same day. The ascitic fluid value is subtracted from the serum value to obtain the gradient. If the difference (not a ratio) is >1.1 g/dl, the patient has portal hypertension, with 97% accuracy. If the difference is <1.1 g/dl, portal hypertension is not present. The majority of patients with SBP have portal hypertension as a result of cirrhosis

IMAGING STUDIES

- Abdominal ultrasound: If there is clinical difficulty in performing paracentesis
- CT scan: To rule out secondary peritonitis (if indicated) and to exclude abscess, mass

TABLE 1 Symptoms and Signs of Ascitic Fluid Infection

	Frequency (%)				
Symptom or Sign	**SBP**	**Bacterascites**	**CNNA**	**Secondary Peritonitis**	**Polymicrobial Bacterascites**
Fever	68	57	50	33	10
Abdominal pain	49	32	72	67	10
Abdominal tenderness	39	32	44	50	10
Rebound tenderness	10	5	0	17	0
Altered mental status	54	50	61	33	0

CNNA, Culture-negative neutrocytic ascites; *SBP,* spontaneous bacterial peritonitis.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TREATMENT

ACUTE GENERAL Rx

- Cefotaxime (2 g IV q8h) or ceftriaxone (2 g IV q24h). Alternative agents include ticarcillin-clavulanate, piperacillin-tazobactam, cefoxitin, and meropenem. Continue therapy for 5 to 7 days. Repeat diagnostic paracentesis can be done at day 2. Repeat paracentesis at 48 hr will demonstrate a significant decrease in polymorphonuclear count in patients with SBP. If ascites PMN count decreases by at least 25% at day 2, IV therapy can be switched to PO (levofloxacin 500 to 750 mg qd) to complete 7 days of therapy if organisms are susceptible.
- IV albumin (1.5 g/kg of body weight upon initial diagnosis and 1 g/kg of albumin on day 3) if BUN >30 mg/dl, serum creatinine >1 mg/dl, bilirubin >4 mg/dl.

PROPHYLAXIS

- Ciprofloxacin 500 mg PO qd or levofloxacin 250 mg PO qd.
- Alternative therapy: TMP-SMX one double-strength tablet PO qd.
- Rifaximin 1200 mg a day was shown in a recent study to be superior to norfloxacin.
- Prophylaxis should be continued until disappearance of ascites or until liver transplantation.

DISPOSITION

The overall mortality rate from an episode of SBP is 20%, and following an episode, the 1-yr mortality rate approaches 70%. Patients that develop SBP should be considered for liver transplantation.

PEARLS & CONSIDERATIONS

COMMENTS

- Renal failure is a major cause of morbidity in cirrhotic patients with SBP. The use of IV albumin (1.5 g/kg at the time of diagnosis and 1 g/kg on day 3) may lower the rate of renal failure and mortality in patients with SBP.
- The criteria for the diagnosis of SBP require that abdominal paracentesis be performed and ascitic fluid be analyzed before a diagnosis of SBP can be made.
- Culturing ascitic fluid as if it were blood (with bedside inoculation of at least 10 ml of ascitic fluid directly into blood culture bottles at the bedside) has been shown to significantly increase the culture positivity of the ascitic fluid in the 80% to 100% range.
- Avoid therapeutic paracenteses during active infection.
- Positive blood cultures in an individual with ascites require exclusion of a peritoneal source by paracentesis.
- Follow-up paracentesis is indicated only in selected cases (worsening clinical status, nosocomial SBP, infection with atypical organism, recent β-lactam exposure).

Sporotrichosis

BASIC INFORMATION

DEFINITION

Sporotrichosis is a granulomatous/pyogenic disease commonly caused by pathogenic strains of the dimorphic fungus *Sporothrix schenckii,* although at least six other pathogenic *Sporothrix* species exist in various geographic regions, such as *Sporothrix brasiliensis*.

SYNONYMS

Lymphocutaneous sporotrichosis
Cutaneous sporotrichosis
Pulmonary sporotrichosis

ICD-10CM CODES

B42.0 Pulmonary sporotrichosis
B42.1 Lymphocutaneous sporotrichosis
B42.7 Disseminated sporotrichosis
B42.8 Other forms of sporotrichosis
B42.9 Sporotrichosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT SEX: The most common form, lymphocutaneous sporotrichosis, occurs equally in both sexes. Males predominate in both pulmonary and osteoarticular sporotrichosis.
PREDOMINANT AGE: Generally, lymphocutaneous sporotrichosis occurs in people 35 yr of age or younger, usually through occupation or hobbies such as landscaping or gardening. Pulmonary sporotrichosis occurs in people between the ages of 30 and 60 yr, often alcoholic men with COPD and diabetics. Those with HIV are at risk for disseminated infection.
GENETICS: Neonatal infection: At least one case of transmission from the cheek lesions of the mother to the skin of the infant has been reported.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Cutaneous disease:
  1. Arises at the site of inoculation, often the site of soil exposure (Fig. E1)
  2. Initial lesion usually located on the distal part of an extremity (Fig. E2), although any area may be affected, including the face
  3. Variable incubation period of approximately 3 wk once introduced into the skin
  4. Granulomatous reaction provoked
  5. Lesion becomes papulonodular, erythematous, elastic, variable in size
  6. Subsequently, nodule becomes fluctuant, undergoes central necrosis, breaks down, discharges mucoid pus from which fungus may be isolated
  7. Indolent ulcer with raised erythematous or violaceous borders
  8. Secondary lesions:
     a. Develop along superficial lymphatic channels
     b. Evolve in the same manner as the primary lesion, with subsequent inflammation, induration, and suppuration
- Fixed, or plaque form:
  1. Erythematous verrucous, ulcerated, or crusted lesions
  2. Does not spread locally
  3. Does not involve lymphatic vessels
  4. Rarely undergoes spontaneous resolution
  5. More often persists for yrs without systemic symptoms and within a setting of normal laboratory examinations
- Osteoarticular involvement:
  1. Most common extracutaneous form
  2. Usually presents as monoarticular arthritis
  3. Left untreated, may progress to:
     a. Synovitis
     b. Osteitis
     c. Periostitis
     d. All involving elbows, knees, wrists, and ankles
  4. Joint inflamed:
     a. Associated with an effusion
     b. Painful on motion
- Early pulmonary disease:
  1. Usually associated with a paucity of clinical findings:
     a. Low-grade fever
     b. Cough
     c. Fatigue
     d. Malaise
     e. Weight loss
  2. Untreated:
     a. Cavitary pulmonary disease
     b. Frank pulmonary dysfunction
     c. Hemoptysis
     d. Mimics tuberculosis
  3. Meningitis:
     a. Uncommon except perhaps in the immunocompromised patient
     b. Presents with few signs or symptoms of neurologic involvement, usually headache
  4. Few reported cases:
     a. Infection of the ocular adnexa
     b. Endophthalmitis without antecedent trauma
     c. Infection of the testes and epididymis
     d. Certain strains favor cooler body areas such as the scrotum, lower extremities

ETIOLOGY

- *Sporothrix schenckii:*
  1. Global in distribution
  2. Often isolated from soil, plants, and plant products

FIG. E1 Sporotrichosis. Erythematous papules and nodules on the plantar surface with early lymphangitic (sporotrichoid) spread. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E2 Sporotrichosis of the fifth finger in a gardener. Three nodular lesions are visible on the hand and arm. (From Mandell GL et al: *Principles and practice of infectious diseases,* ed 7, Philadelphia, 2010, WB Saunders.)

3. Majority of case reports from tropical and subtropical regions of the Americas
- Occupational or recreational exposure:
  1. Hay
  2. Straw
  3. Sphagnum moss
  4. Timber
  5. Thorny plants (e.g., roses and barberry bushes)
- Animal contact:
  1. Armadillos
  2. Cats
  3. Squirrels
- Tattooing

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fixed, or plaque, sporotrichosis:
  1. Bacterial pyoderma
  2. Foreign body granuloma
  3. Tularemia
  4. Anthrax
  5. Other mycoses: Blastomycosis, chromoblastomycosis
- Lymphocutaneous sporotrichosis:
  1. *Nocardia brasiliensis*
  2. *Leishmania braziliensis*
  3. Atypical mycobacterial disease: *Mycobacterium marinum, Mycobacterium kansasii*
- Pulmonary sporotrichosis:
  1. Pulmonary TB
  2. Histoplasmosis
  3. Coccidioidomycosis
- Osteoarticular sporotrichosis:
  1. Pigmented villonodular synovitis
  2. Gout
  3. Rheumatoid arthritis
  4. Infection with *Mycobacterium tuberculosis*
  5. Atypical mycobacteria: *Mycobacterium marinum, Mycobacterium kansasii, Mycobacterium avium-intracellulare*
- Meningitis:
  1. Histoplasmosis
  2. Cryptococcosis
  3. TB

WORKUP

- The diagnosis should be considered in individuals who are occupationally exposed to soil, decaying plant matter, and thorny plants (gardeners, horticulturists, farmers) who present with chronic nonhealing ulcers or lesions with or without associated arthritis or pulmonary symptoms.
- Diagnosis is made by culture:
  1. Pus
  2. Joint fluid
  3. Sputum
  4. Blood
  5. Skin biopsy
- Isolation of the fungus from any site is considered diagnostic of infection.
- Saprophytic colonization of the respiratory tract has been described.
- A positive blood culture may indicate infection in an immunocompromised host.
- Increasingly sensitive laboratory culturing systems may detect the fungus in the normal host.
- Biopsy specimens are diagnostic if characteristic cigar-shaped, round, oval, or budding yeast forms are seen.
- Despite special staining, the yeast may remain difficult to detect unless multiple sections are examined, as organisms are rare.
- No standard method of serologic testing is available.

LABORATORY TESTS

- CBCs and serum chemistries are generally normal.
- Elevated ESR is seen with extracutaneous disease.
- CSF analysis in meningeal disease reveals:
  1. Lymphocytic pleocytosis
  2. Elevated protein
  3. Hypoglycorrhachia
- Nested polymerase chain reaction (PCR) assay represents a future clinical modality to rapidly detect *Sporothrix schenckii*.
- Matrix-assisted laser desorption ionization-time of flight (MALDI-TOF) has been used to identify *Sporothrix* grown in culture to the species level.

IMAGING STUDIES

- Chest x-ray examination: Unilateral or bilateral upper lobe cavitary or noncavitary lesions
- Radiographic findings of affected joints:
  1. Loss of articular cartilage
  2. Periosteal reaction
  3. Periarticular osteopenia
  4. Cystic changes

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Local heat and prevention of bacterial superinfection in cutaneous or plaque form. This treatment is important for pregnant women as azoles are teratogenic.

ACUTE GENERAL Rx

CUTANEOUS AND LYMPHOCUTANEOUS SPOROTRICHOSIS:

- Itraconazole at doses of 200 mg/day is the drug of choice and should be given for 2 to 4 wk after the lesions have resolved.
- Alternative treatment: Use saturated solution of potassium iodide (SSKI) 5 to 10 drops PO tid or 1.5 ml PO tid, gradually increasing to 40 to 50 drops PO tid or 3 ml PO tid after meals.
- Maximum tolerated dose should be continued until cutaneous lesions have resolved, approximately 6 to 12 wk.
- Adjunctive therapy with heat is useful and occasionally curative.
- Side effects of SSKI:
  1. Nausea
  2. Anorexia
  3. Diarrhea
  4. Parotid or lacrimal gland hypertrophy
  5. Acneiform rash

DEEP-SEATED MYCOSES (OSTEOARTICULAR, NONCAVITARY PULMONARY DISEASE):

- Itraconazole:
  1. Appropriate initial chemotherapy
  2. Less toxic than amphotericin B
  3. 200 mg PO bid for 1 to 2 yr with continued lifelong suppressive therapy in selected patients
  4. Absence of relapses from 40 to 68 mo has been documented when at least 200 mg/day administered for 24 mo
  5. Insufficient data for use in disseminated disease (e.g., fungemia and meningitis)
  6. Drug levels should be monitored to assess absorption
- Parenteral amphotericin B, total course of 2 to 2.5 g or more, results in cure in approximately two thirds of cases. Lipid AmB 3 to 5 mg/kg/day is also recommended and less toxic.
  1. Relapses are common.
  2. Amphotericin B-resistant isolates of *Sporothrix schenckii* have been reported.
  3. Remains the drug of choice for severely ill patients with disseminated disease.
  4. In cavitary pulmonary disease, given perioperatively as an adjunct to surgical resection.
  5. When patient is improved, can continue treatment with itraconazole 200 mg PO bid.
  6. Treat for at least 12 mo.
  7. The latest IDSA guidelines recommend fluconazole only as an alternative treatment for lymphocutaneous disease.
  8. Requires daily doses of 400 mg/day for lymphocutaneous disease and 800 mg/day for visceral or osteoarticular disease.
  9. Fluconazole much less effective than itraconazole.
  10. All azoles are teratogenic in pregnancy.

CHRONIC Rx

For lymphocutaneous and visceral disease, therapy with itraconazole 200 mg/day for periods of 24 mo or greater. *Sporothrix* is resistant to voriconazole. It is sensitive in vitro to posaconazole, but existing data are very limited at present.

DISPOSITION

- Prognosis for cutaneous disease is good.
- Prognosis is less satisfactory for extracutaneous disease, especially if associated with abnormal immunologic states or other underlying systemic diseases.

REFERRAL

- To surgeon; with an established diagnosis of pulmonary sporotrichosis, cavitary lesions require resection of involved tissue and possible pretreatment with amphotericin
- To infectious disease physician

PEARLS & CONSIDERATIONS

COMMENTS

- In patients with underlying immunosuppression (e.g., hematologic malignancy or infection with HIV), progression of the initial infection may develop into multifocal extracutaneous sporotrichosis.

- In this subset of patients, dissemination of cutaneous lesions is accompanied by hematogenous spread to lungs, bone, mucous membranes, CNS.
- Osteoarticular and pulmonary manifestations predominate with the development of polyarticular arthritis and osteolytic bone lesions.
- In the absence of therapy, the infection is ultimately fatal.
- Patients with underlying immunosuppressive states should be carefully evaluated even when presenting with single cutaneous lesions.
- Diagnostic modalities should include:
  1. Radiographic examination of chest
  2. Technetium pyrophosphate bone scan
  3. Culture of synovial fluid, blood, skin lesion(s)
- In patients with AIDS, itraconazole appears to be the drug of choice, although meningitis and pulmonary disease may warrant the use of amphotericin B.
- In patients with AIDS, lifetime suppressive therapy with itraconazole should follow initial therapy because of the potential for relapse and dissemination. Treatment may be terminated when CD4 counts exceed 200 for more than 1 yr.
- Disseminated cases have been reported with the use of TNF-alpha inhibitors.

Squamous Cell Carcinoma ALG PTG

BASIC INFORMATION

DEFINITION

Squamous cell carcinoma (SCC) is a malignant neoplasm of keratinocytes.

SYNONYMS

SCC
Skin cancer

ICD-10CM CODES

C44.5	Malignant neoplasm of skin of trunk
C44.4	Malignant neoplasm of skin of scalp and neck
D04	Carcinoma in situ of skin
C44.9	Malignant neoplasm of skin, unspecified
C44.0	Malignant neoplasm of skin of lip
C44.2	Malignant neoplasm of skin of ear and external auricular canal
C44.3	Malignant neoplasm of skin of other and unspecified parts of skin
C44.02	Squamous cell carcinoma of skin of lip
C44.121	Squamous cell carcinoma of skin of unspecified eyelid, including canthus
C44.122	Squamous cell carcinoma of skin of right eyelid, including canthus
C44.129	Squamous cell carcinoma of skin of left eyelid, including canthus
C44.221	Squamous cell carcinoma of skin of unspecified ear and external auricular canal
C44.222	Squamous cell carcinoma of skin of right ear and external auricular canal
C44.229	Squamous cell carcinoma of skin of left ear and external auricular canal
C44.320	Squamous cell carcinoma of skin of unspecified parts of face
C44.321	Squamous cell carcinoma of skin of nose
C44.329	Squamous cell carcinoma of skin of other parts of face
C44.42	Squamous cell carcinoma of skin of scalp and neck
C44.520	Squamous cell carcinoma of anal skin
C44.521	Squamous cell carcinoma of skin of breast
C44.529	Squamous cell carcinoma of skin of other part of trunk
C44.621	Squamous cell carcinoma of skin of unspecified upper limb, including shoulder
C44.622	Squamous cell carcinoma of skin of right upper limb, including shoulder
C44.629	Squamous cell carcinoma of skin of left upper limb, including shoulder
C44.721	Squamous cell carcinoma of skin of unspecified lower limb, including hip
C44.722	Squamous cell carcinoma of skin of right lower limb, including hip
C44.729	Squamous cell carcinoma of skin of left lower limb, including hip
C44.82	Squamous cell carcinoma of overlapping sites of skin

EPIDEMIOLOGY & DEMOGRAPHICS

- SCC is the second most common cutaneous malignancy, comprising 20% of all cases of nonmelanoma skin cancer.
- Incidence is highest in lower latitudes (e.g., southern U.S., Australia).
- Male:female ratio is 2:1.
- Incidence increases with age and sun exposure.
- In black patients, SCC are 20% more common than basal cell carcinomas (BCC).
- Average age at diagnosis is 66 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- SCC frequently begins at the site of actinic keratosis and commonly affects the scalp, neck region, back of hands (Fig. E1), superior surface of the pinna, and the lip (Fig. E2). On the lower lip, SCC often develops on actinic cheilitis. A history of smoking is a significant predisposing factor.
- Bowen disease refers to SCC in situ (Fig. E3).
- SCC lesions may have a scaly, erythematous macule or plaque (Fig. E4).
- Telangiectasia, central ulceration may also be present. The ulcer may be superficial and hidden by a crust. Removal of the crust may reveal a well-defined papillary base.
- Most SCCs present as exophytic lesions that grow over a period of mo.
- Although most SCCs are relatively slow growing and nonaggressive, some (2% to 5%) can exhibit rapid growth and metastases. Aggressive tumors are more common in immunocompromised patients and when arising from scars, burns, or prior injury (Marjolin ulcer). Presence of SCC on ears, lips, or size >2 cm are high-risk features of SCC.

ETIOLOGY

Risk factors include ultraviolet B radiation, immunosuppression (kidney transplant recipients have a significantly increased risk), arsenic exposure, HPV infection, medications (azathioprine, sorafenib, tumor necrosis factor [TNF] inhibitors), discoid LE, erosive lichen planus, chronic ulcers, prior radiation exposure, and tobacco abuse.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Keratoacanthomas
- Actinic keratosis
- Amelanotic melanoma
- Basal cell carcinoma
- Benign tumors
- Healing traumatic wounds
- Spindle cell tumors
- Warts

WORKUP

Diagnosis is made by full-thickness skin biopsy (incisional or excisional).

TREATMENT

ACUTE GENERAL Rx

- Electrodesiccation and curettage for small SCCs (<2 mm in diameter), superficial tumors, and lesions located in extremity and trunk.
- Tumors thinner than 4 mm can be managed by simple local removal.
- Lesions 4 to 8 mm thick or those with deep dermal invasion should be excised.
- Tumors penetrating the dermis can be treated with several modalities, including excision and Mohs surgery, radiation therapy, and chemotherapy. Mohs surgery is commonly used for lesions on the face.
- Metastatic SCC can be treated with cryotherapy and combination of chemotherapy using 13-*cis*-retinoic acid and interferon-alpha 2A.
- A treatment algorithm for squamous cell carcinoma is illustrated in Fig. 5.
- In a recent phase 1 study of PD-1 blockade with cemiplimab among patients with advanced cutaneous squamous cell carcinoma, cemiplimab induced a response in approximately half the patients.[1]

DISPOSITION

- Survival is related to size, location, degree of differentiation, immunologic status of the patient, depth of invasion, and presence of metastases. Risk factors for metastasis include lesions on the lip or ear, increasing lesion depth, and poor cell differentiation. Table 1 summarizes risk factors for metastasis of invasive squamous cell carcinoma.
- Patients whose tumors penetrate through the dermis or exceed 8 mm in thickness are at risk of tumor recurrence.
- The most common metastatic locations are regional lymph nodes, liver, and lung.
- Tumors on the scalp, forehead, ears, nose, and lips also carry a higher risk.
- The rate of SCC metastasis from all skin sites ranges from 0.5% to 5.2%.
- SCCs originating in the lip and pinna metastasize in 10% to 20% of cases.
- 5-yr survival for metastatic SCC is 34%.

REFERRAL

Oncology referral for metastatic SCC

PEARLS & CONSIDERATIONS

COMMENTS

- SCC arising in areas of prior radiation, thermal injury, and areas of chronic ulcers or chronic draining sinuses are more aggressive and have a higher frequency of metastasis than those originating in actinic damaged skin.

[1] Migden MR et al: PD-1 blockade with cemiplimab in advanced cutaneous squamous-cell carcinoma, *N Engl J Med* 379:341-51, 2018.

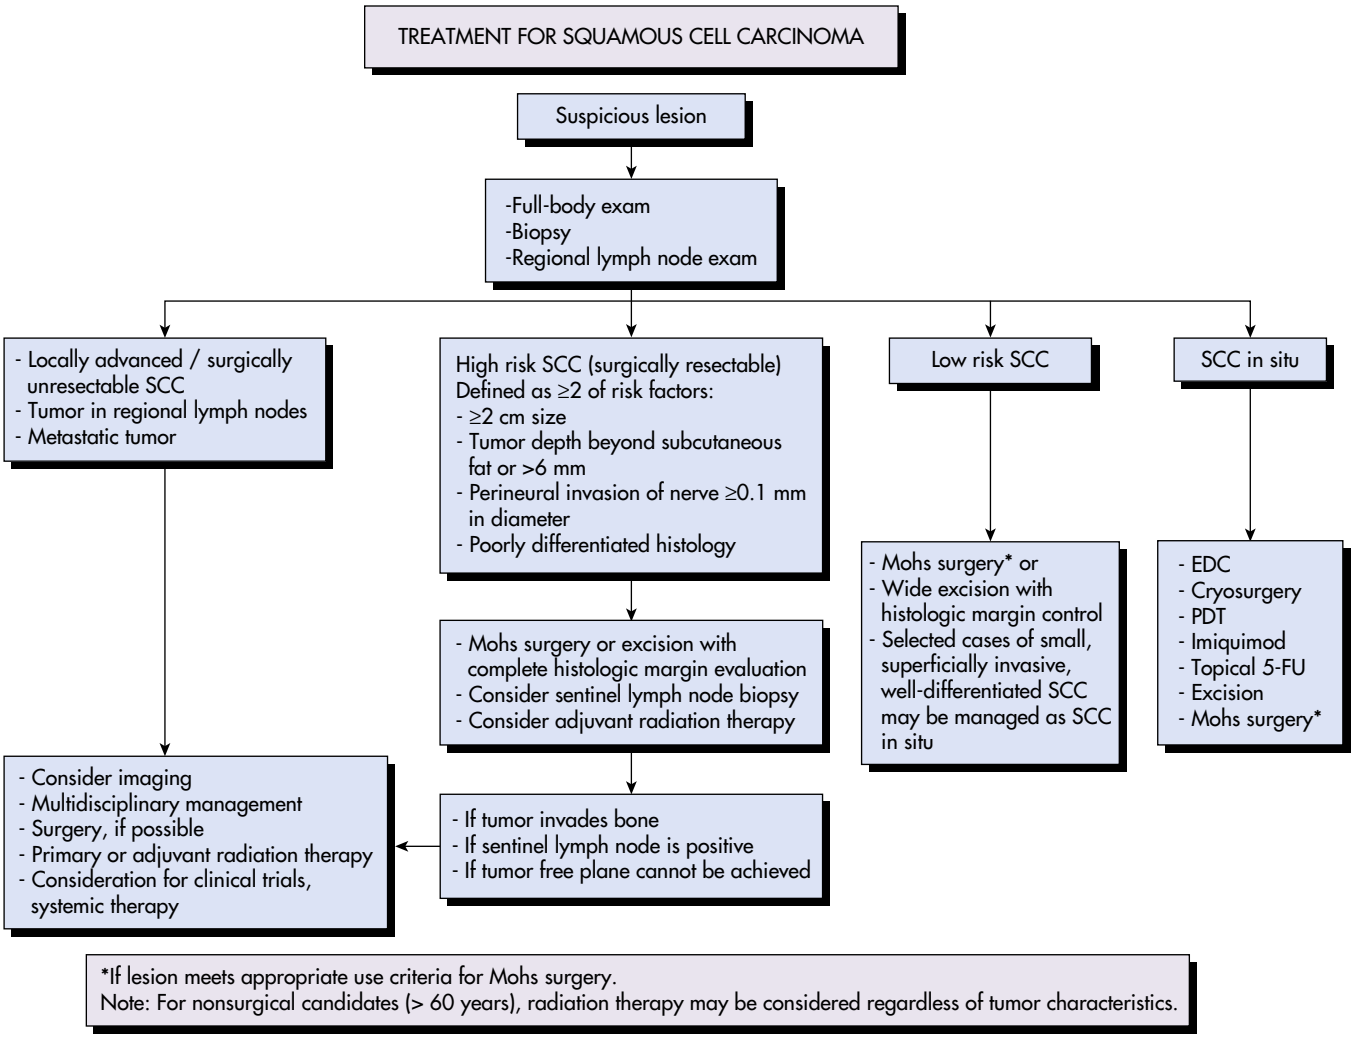

FIG. 5 Treatment algorithm for squamous cell carcinoma *(SCC).* *EDC,* Electrodesiccation and curettage; *5-FU,* 5-fluorouracil; *PDT,* photodynamic therapy. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

TABLE 1 Risk Factors for Metastasis of Invasive Squamous Cell Carcinoma

Tumor thickness: >2 mm (high risk: tumor thickness >6 mm)
Diameter: >2 cm
Location: Ear, lips, and mucosae, including tongue, vulva, and penis (perineural growth may be an additional risk factor in these locations)
Arising within a scar (e.g., burn, radiation)
Histopathologic features: Poorly differentiated or undifferentiated, acantholytic,* developing within Bowen disease
Immunosuppression

*Recently questioned Ogawa T et al: Acantholytic squamous cell carcinoma is usually associated with hair follicles, not acantholytic actinic keratosis, and is not "high risk": diagnosis, management, and clinical outcomes in a series of 115 cases, *J Am Acad Dermatol* 76:327-333, 2017.

Based in part on Brantsch KD et al: Analysis of risk factors determining prognosis of cutaneous squamous-cell carcinoma: a prospective study, *Lancet Oncol* 9:713-720, 2008.

- Oral retinoids may be useful as a preventive strategy in patients with immunosuppression.
- Nicotinamide (500 mg bid, available over the counter) mitigates some of the deleterious effects of UV radiation and has been reported to lower the incidence of nonmelanoma skin cancer (NMSC0) by 23%.[2]

FIG. E1 Squamous cell carcinoma. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

FIG. E2 Squamous cell carcinoma of the lip. The lower lip **(A)** is a relatively commonly affected site. Smoking is a risk factor for this site, and the prognosis is poorer compared to similar-sized lesions at other sun-exposed sites. Treatment is usually by wedge excision or with radiotherapy. By contrast, the upper lip margin **(B)** is a relatively uncommon site. The chronic trauma from the patient's only three teeth may have been relevant. (From White GM, Cox NH [eds]: *Diseases of the skin, a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

FIG. E3 Squamous cell carcinomas *in situ,* Bowen disease type. A, Scaly red plaque on the chest with skip areas and background photodamage. **B,** Larger broken-up pink plaque with scale-crust in the pubic region, a sun-protected site. This type of lesion often is misdiagnosed as dermatitis or psoriasis and treated with topical corticosteroids. **C,** Bright red, well-demarcated plaque on the proximal nail fold with associated horizontal nail ridging; the possibility of HPV infection needs to be considered. **D,** Dermoscopic findings of tiny dotted vessels in the upper half of the lesion combined with superficial scales. **E,** Extensive involvement of the finger that was misdiagnosed clinically as an inflammatory dermatosis and treated for yrs with corticosteroid creams. (From Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier. **B,** Courtesy Kalman Watsky, MD; **D,** Courtesy, Iris Zalaudek, MD)

FIG. E4 Squamous cell carcinoma *in situ,* erythroplasia of Queyrat type. Large, eroded erythematous plaque with well-demarcated borders. The lesion began on the shaft of the penis. (From Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.)

Statin-Induced Muscle Syndromes

BASIC INFORMATION

DEFINITION

Statin-induced muscle syndromes (SIMS) include myopathy, myalgia, myositis, and rhabdomyolysis. Definitions for these syndromes are inconsistent in the medical literature.

- Myopathy: A general term defined as any disease of muscles.
- Myalgia: Muscle weakness or pain without serum creatinine kinase elevation.
- Myositis: Muscle weakness or pain with an increased serum creatinine kinase level.
- Rhabdomyolysis: Muscle weakness or pain and a marked serum creatinine kinase level usually greater than 10× the upper limit of normal and serum creatinine elevation as well as signs of brown urine and elevated urine myoglobin. A rare **immune-mediated necrotizing myopathy (IMNM),** also known as **statin-associated autoimmune myopathy,** has also been associated with the use of statins with symptoms persisting after discontinuation of the drug. This condition presents with symmetric proximal arm and leg weakness and severe elevations of muscle enzymes.

SYNONYMS

SIMS
Statin-induced myopathies
Statin-induced myositis
Statin-induced myalgias
Statin-induced rhabdomyolysis
Statin-associated autoimmune myopathy

ICD-10CM CODES

M60.9	Myositis, unspecified
M62.82	Rhabdomyolysis
G72.2	Myopathy due to other toxic agents
G72.9	Myopathy, unspecified
G72.81	Critical illness myopathy
G72.89	Other specified myopathies
M60.89	Other myositis, multiple sites

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Risk of statin-induced rhabdomyolysis is 1.2 per 10,000 persons/yr. Rhabdomyolysis risk of death is 0.15 deaths per 1 million prescriptions. SIMS most commonly occur in people aged 51 to 75, which may reflect the pattern of statin use. Statin-associated autoimmune myopathy occurs in an estimated 2 or 3 of every 100,000 patients treated with statins.

PEAK INCIDENCE: Patients on high-dose statins have a 0.9% incidence of statin-induced rhabdomyolysis.

PREVALENCE: The prevalence of statin-induced myalgias is about 1% to 5%, similar to placebo in clinical trials, although observational studies have suggested a prevalence of 10% or higher. Statins may cause elevated transaminases (ALT, AST) at a prevalence of 0.5% to 2.0% and rhabdomyolysis ~0.08%.

PREDOMINANT SEX AND AGE: The mean age of hospitalized patients with statin-induced myopathy or rhabdomyolysis was 64 yr old and was slightly more common in women (56%).

GENETICS: Interpatient variability exists in the activity of the *CYP3A4* gene for the metabolism of simvastatin, atorvastatin, and lovastatin. Homozygous carriers of *CYP2D6* (poor metabolizers) had a higher rate of discontinuation of simvastatin due to muscle syndromes compared with the *CYP2D6* wild-type genotype; patients taking atorvastatin and having a muscle event were more likely to have the CYP2D6*4 allele. *SLCO1B1* polymorphisms encode for the organic anion transport of statins into the liver cells. The variant C allele may increase the risk of the *SLCO1B1* statin–induced myopathy. Simvastatin-induced myopathy is more likely to be associated with *SLO1B1* genotype and not *ABCB1* genotype. However, a statin-associated autoimmune myopathy has shown a link to class II HLA allele DRB1*11:01 in the development of anti-HMG CoA reductase antibodies, leading to an increase in expression of the antibodies in the muscles of patients exposed to statins. Deficiencies in ubiquinone (coenzyme Q10) may exist in patients with a mutation in the *COQ2* gene. The *EYS* gene can affect neuromuscular tissue and may have a role. In addition, *RYR1* and *CACNA1S* genetic variants may be associated with statin-induced muscle syndromes and elevated CK levels.

RISK FACTORS: Small body frame; age over 80 yr; women, particularly frail elderly women; patients taking multiple drugs, especially gemfibrozil, niacin, cyclosporine, itraconazole, ketoconazole, erythromycin, clarithromycin, verapamil, amiodarone; renal or liver impairment; pharmacogenetic variability; hypothyroidism; excessive alcohol intake; vigorous exercise; severe infections; excessive grapefruit juice ingestion; low vitamin D levels; inherited defects of muscle metabolism such as carnitine palmityl transferase II deficiency, McArdle disease, and myoadenylate deaminase deficiency; acquired myopathies such as postpoliomyelitis syndrome; lipophilic statins (simvastatin, atorvastatin, lovastatin); multiple conditions such as diabetes; renal impairment, and prior elevated CK; and drugs of abuse (amphetamines, heroin, cocaine, phencyclidine).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Myopathy can occur at any time, although it is more common within the first 4 wk of therapy; statin-associated necrotizing myopathy may occur after mos of using statins
- Proximal generalized muscle aches, body aches, and pains, and may be mild or severe
- Dark-colored urine
- Muscle cramps, spasms, tenderness, or stiffness
- Unusually tired or weak
- Nocturnal cramping
- Tendon pain

ETIOLOGY

- History of current statin use.
- May be explained by one of three deficiencies of end products of the 3-hydroxy-3-methylglutaryl-coA reductase pathway: cell signaling and apoptosis, mitochondrial function and ubiquinone concentrations, and cholesterol concentrations and cell membrane integrity.
- The risk may be enhanced by drug interactions that interfere with hepatic metabolism and gut wall transport of interacting medications and by pharmacodynamic effects.
- Underlying metabolic muscle disorder may predispose a patient to develop myopathy.
- Patients with statin-associated autoimmune myopathy have been found to have anti-HMG-CoA reductase antibodies even prior to exposure to statin therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Bursitis, tendinitis, radiculopathy, osteoarthritis, muscle strain, myofascial pain, hypothyroidism, proton pump inhibitor–induced polymyositis, viral illness, polymyositis, idiopathic inflammatory myositis, and polymyalgia rheumatica

WORKUP

Workup consists of a thorough history, including exercise history, urine color, medication history, and physical exam to palpate tenderness and obtain blood tests to evaluate muscle and kidney damage.

LABORATORY TESTS

If severe myopathy or rhabdomyolysis is suspected:

- Elevated CPK, positive serum myoglobin, elevated BUN, serum creatinine, AST, ALT, LDH, and potassium
- Urine creatinine, positive casts, and hemoglobin in urine with absence of red blood cells
- Anti-3-hydroxy-3-methylglutaryl-conenzyme A (anti-HMG-CoA) antibody
- Consider electrocardiogram and assessment of calcium, phosphate, and uric acid

If mild to moderate myopathy is suspected:

- Monitor TSH and CPK levels; CPK may only be elevated when sudden severe myopathy occurs.
- If the patient has brown or dark urine or elevated CPK, monitor BUN and serum creatinine.
- In statin-associated autoimmune myopathy, the creatine kinase level is usually ≥10 times the upper limit of normal. In these patients, muscle biopsy specimens will be positive for autoantibodies against HMG-CoA reductase and may have necrosis.

IMAGING STUDIES

- Not recommended.
- In statin-associated autoimmune myopathy, electromyography shows small-amplitude motor-unit potentials with increased spontaneous activity characteristic of an active myopathic process. Muscle edema is evident on MRI.[1]
- Statin Intolerance Tool:
  1. The American College of Cardiology has created a tool to assess statin muscle symptoms and to guide clinicians that can be of value: http://tools.acc.org/statinintolerance/#!/

[1]Mammen AL: Statin-associated autoimmune myopathy, *N Engl J Med* 374:664-669, 2016.

TREATMENT

NONPHARMACOLOGIC THERAPY

Treatment of rhabdomyolysis is generally supportive in nature (see "Rhabdomyolysis" topic).

ACUTE GENERAL Rx

- Stop statin therapy immediately if muscle symptoms occur. Check history, potential drug-drug interactions, CPK, TSH, renal function, hepatic function, and urinalysis.
- If patients have suspected rhabdomyolysis, they should be hospitalized and treated with supportive therapy and monitoring of complications.
- If CPK <10× the upper limit of normal without symptoms, continue statin therapy at the same or lower dosage.
- If CPK <10× the upper limit of normal with intolerable symptoms, discontinue statin.
- If CPK >10× the upper limit of normal, discontinue statin.

Box E1 describes recommendations of the National Lipid Association Statin Safety Assessment Task Force regarding statin and muscle safety.

CHRONIC Rx

- After stopping the statin and symptom or CPK resolution, which may take up to 4 mo, consider the same statin at a lower dosage or a different statin at an equivalent or lower dosage.
- When restarting therapy, consider statins such as low-dose rosuvastatin; pravastatin; and alternate-day dosing of rosuvastatin or atorvastatin.
- If patient had rhabdomyolysis secondary to statin therapy, consider nonstatin treatments.
- If the patient develops myopathy after a second trial of therapy, statin treatment should be permanently discontinued and nonstatin cholesterol-lowering therapy initiated.
- For IMNM (statin-associated autoimmune myopathy and idiopathic inflammatory myositis), immunosuppressive therapy with prednisone (1 mg per kg of body weight per day) and at least one agent (methotrexate, azathioprine, or mycophenolate mofetil) have been used. In resistant cases, IV immune globulin or another agent such as rituximab may be added.

INTEGRATIVE MEDICINE

- The effect of coenzyme Q10 on reducing or preventing SIMS remains controversial; although it may be effective in reducing muscle pain, weakness, cramps, and tiredness, it has no effect on lowering CK levels. Given its safety, coenzyme Q10 can be recommended if the actions listed under "Chronic Rx" are insufficient to continue the use of the statin and if the muscle symptoms have been limited to myalgias. Use coenzyme Q10 with caution in patients taking warfarin, as its anticoagulant effect may be decreased.
- A 2015 meta-analysis of observational studies reported that vitamin D levels were lower in patients with statin-induced myalgias than in individuals who did not have these symptoms.
- In a study of 282 patients with vitamin D levels less than 32 ng/ml and with myalgia-myositis from statins, vitamin D supplementation (median 50,000 IU D_3/wk) for 6 mo improved symptoms and statin tolerance in 74% to 85% of patients; another study showed that replacement of vitamin D in patients with low-serum vitamin D may be able to maintain or restart previously failed statin therapy.

DISPOSITION

- Usually resolves within 1 wk up to 4 mo after discontinuing statin therapy.
- Once the patient has a full recovery, an alternative statin can be tried.
- Statins should not be restarted in IMNM or idiopathic inflammatory myositis.

REFERRAL

If rhabdomyolysis is suspected, immediate referral for hospitalization is suggested.

PEARLS & CONSIDERATIONS

COMMENTS

SIMS are usually mild and will resolve within a few wk after discontinuing statin therapy. However, such syndromes may progress to rhabdomyolysis.

PREVENTION

- Follow the 2013 AHA/ACC treatment guidelines and the 2017 ACC focused update on nonstatin therapies for LDL cholesterol and limit the concomitant use of fibrates with statins.
- Discontinue statin therapy prior to and during surgical procedures.
- If patient requires a short-term therapy with an interacting medication such as an azole antifungal, temporarily discontinue statin therapy until interacting therapy is completed.
- If statin–fibric acid therapy is warranted, fenofibrate is preferred over gemfibrozil to decrease risk of myopathy.
- Baseline liver function testing before initiation of statin therapy and only if clinically indicated thereafter.

PATIENT & FAMILY EDUCATION

- Inform patients to promptly report muscle weakness, unexpected muscle pain, or brownish urine.
- Ensure that the pharmacist and/or primary care physician checks for drug-drug interactions with every new prescription, including those from dentists and physicians from other specialties.
- Coenzyme Q10 may lessen milder muscle symptoms from statins, but patients should inform their physician and pharmacist if they decide to use this supplement.
- A recent clinical trial comparing lipid-lowering efficacy for two nonstatin therapies, ezetimibe and evolocumab, among patients with statin intolerance revealed that evolocumab resulted in a significantly greater reduction in LDL-C levels after 24 wk. Further studies are needed to assess long-term efficacy and safety.

BOX E1 Recommendations to Health Care Professionals Regarding Statin and Muscle Safety

- Whenever muscle symptoms or an increased CK level is encountered in patients receiving statin therapy, health professionals should attempt to rule out other causes, because these are most likely to explain the findings. Other common causes include increased physical activity, trauma, falls, accidents, seizure, shaking chills, hypothyroidism, infections, carbon monoxide poisoning, polymyositis, dermatomyositis, alcohol abuse, and drug abuse (cocaine, amphetamines, heroin, or PCP).
- Obtaining a pretreatment, baseline CK level can be considered in patients who are at high risk of experiencing muscle toxicity (e.g., older patients or those combining a statin with an agent known to increase myotoxicity), but this is not routinely necessary in other patients.
- It is unnecessary to measure CK levels in asymptomatic patients during the course of statin therapy, because marked, clinically important CK elevations are rare and are usually related to physical exertion or other causes.
- Patients receiving statin therapy should be counseled about the increased risk of muscle symptoms, particularly if initiation of vigorous, sustained endurance exercise or a surgical operation is being contemplated; they should be advised to report such muscle symptoms to a health professional.
- Creatine kinase measurements should be obtained in symptomatic patients to help gauge the severity of muscle damage and facilitate decision of whether to continue therapy or alter doses.
- In patients who develop intolerable muscle symptoms with or without CK elevation and for whom other etiologies have been ruled out, the statin should be discontinued. Once symptoms disappear, the same or different statin at the same or a lower dose can be restarted to test the reproducibility of symptoms. Recurrence of symptoms with multiple statins and doses requires initiation of other lipid-altering therapy.
- In patients who develop tolerable muscle symptoms or have no symptoms but have a CK level <10× ULN, statin therapy may be continued at the same or reduced doses and symptoms may be used as the clinical guide to stop or continue therapy.
- In patients who have positive anti-HMG-CoA antibodies and statin-associated necrotizing autoimmune myopathy, more aggressive immunosuppressant treatments may be necessary.
- In patients who develop rhabdomyolysis (CK >10,000 IU/L or >10× ULN with an elevation in serum creatinine or need for intravenous hydration therapy), statin therapy should be stopped. Intravenous hydration therapy in a hospital should be instituted if indicated for patients experiencing rhabdomyolysis. Once patients recover, risk versus benefit of statin therapy should be carefully reconsidered.

CK, Creatine kinase; PCP, phencyclidine; ULN, upper limit of normal.
From McKenney JM et al: Final conclusions and recommendations of the National Lipid Association Statin Safety Assessment Task Force, *Am J Cardiol* 97(suppl 8A):89C-94C, 2006.

Status Epilepticus

BASIC INFORMATION

DEFINITION

Status epilepticus is a medical neurologic emergency. It is historically defined as 30 min of continuous seizure activity or two or more seizures without full recovery of consciousness between seizures. However, in practice a continuous seizure that lasts >5 min is treated as status epilepticus.

SYNONYMS

Convulsive status epilepticus
Nonconvulsive status epilepticus

ICD-10CM CODES

G41	Status epilepticus
G40.301	Generalized idiopathic epilepsy and epileptic syndromes, not intractable, with status epilepticus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 40 to 100 cases per 100,000 persons
PEAK INCIDENCE: It is most common among children younger than 1 yr and adults older than 60 yr.
PREDOMINANT SEX AND AGE: No gender preference

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients can present with repetitive tonic-clonic movements of the body (convulsive status epilepticus); other patients are comatose and nonresponsive (nonconvulsive status epilepticus).
- Patients may also present with lethargy, intermittent confusion, and involuntary movements.

ETIOLOGY

- Status epilepticus can be the result of an acute neurologic injury, such as stroke, meningitis, brain tumor, etc. Table 1 summarizes causes of status epilepticus in adults presenting in the community.
- In patients with epilepsy, abrupt discontinuation of antiepileptic drugs can result in status epilepticus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Convulsive syncope
- Encephalopathies: Metabolic, infectious, toxic, etc.
- Nonepileptic spells

WORKUP

- ABCs
- ICU admission
- Emergent electroencephalogram (EEG)
- Continuous video EEG in refractory cases
- Table 2 describes a suggested timetable for emergency diagnosis and treatment of status epilepticus. A treatment approach is summarized in Table 3 and Fig. 1.

LABORATORY TESTS

- Routine blood workup (CBC, CMP, glucose, electrolytes)

TABLE 1 Causes of Status Epilepticus in Adults Presenting from the Community

Previous Seizures	No Previous Seizures
Common	
Subtherapeutic anticonvulsant	Ethanol-related
Ethanol-related	Drug toxicity
Intractable epilepsy	CNS infection
	Head trauma
	CNS tumor
Less Common	
CNS infection	Metabolic aberration
Metabolic aberration	Stroke
Drug toxicity	
Stroke	
CNS tumor	
Head trauma	

CNS, Central nervous system.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

- Urine drug screen
- Lumbar puncture and CSF analysis in patients with suspected infectious meningitis or encephalitis or suspected autoimmune or paraneoplastic encephalitis

IMAGING STUDIES

- Immediate CT scan of the head.
- MRI of the brain with and without contrast should be performed once the patient is in a stable condition.

TREATMENT

- Patients with continuous seizure activity over 3 min need intravenous lorazepam 0.1 mg/kg at 2 mg/min (or diazepam 0.2 mg/kg at 5 mg/min only when lorazepam is not available).
- In the absence of intravenous access, intramuscular administration of midazolam 10 mg in an adult is a superior alternative.
- Failure of response to lorazepam or midazolam is referred to as established status epilepticus and should be followed by second-line therapy of intravenous fosphenytoin 20 mg/kg (PE) at a rate not greater than 150 mg/min, phenytoin 20 mg/kg IV at up to 50 mg/min as tolerated, intravenous valproic acid 40 mg/kg IV, or intravenous levetiracetam 60 mg/kg IV. Vital signs should be monitored during the infusion.
- If seizures continue, an additional infusion of intravenous valproate, levetiracetam, lacosamide, or brivaracetam or continuous

TABLE 2 Suggested Timetable for Emergency Diagnosis and Treatment of Status Epilepticus

Time	Exam/Intervention	Testing
Initial presentation: 0 min	Airway, breathing, circulation, IV access, monitoring	Glucose, oxygenation via pulse oximetry ± blood gas analysis
Primary survey: 5 min	Neurologic exam Administer antiepileptic drugs Lorazepam, 0.1 mg/kg IV Phenobarbital, 20 mg/kg IV Normal saline maintenance IV Reduce fever	Electrolytes, renal and liver function, ammonia, anticonvulsant levels, toxicology, complete blood cell count, urinalysis
Secondary survey: 15-30 min	Evaluate treatment results Second-line antiepileptic drug if seizure persists Fosphenytoin, 20 mg/kg IV, or phenytoin, 20 mg/kg IV	Patient-specific: Cranial imaging (CT vs. MRI), lumbar puncture, EEG, ECG
Status epilepticus: >30 min	Intubation and mechanical ventilation	
Refractory status epilepticus: >60 min	Titrate antiepileptic drug to burst suppression Pentobarbital, 10 mg/kg IV given over 30 min, then 5 mg/kg every hour for 3 doses, then 1 mg/kg/h; titrate to effect Midazolam, 0.15 mg/kg IV, then 1-2 μg/kg/min, titrate to effect Phenobarbital, 5-10 mg/kg IV every 20 minutes to achieve burst suppression, then every 12 hours Evaluate need for vasopressors	Continuous EEG Neurologic consultation Consider anesthesia consultation for treatment with inhaled anesthetic

CT, Computed tomography; *ECG,* electrocardiogram; *EEG,* electroencephalogram; *IV,* intravenous; *MRI,* magnetic resonance imaging.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

TABLE 3 Treatment Approach to Status Epilepticus

1. Appropriate critical care treatment should be provided as soon as possible and simultaneously with emergent initial therapy for seizures. Treatment should be escalated quickly until seizures are controlled.
   1a. Critical care treatment (dictated by clinical circumstances):
   a. Intubation for airway protection and mechanical ventilation
   b. Vital sign monitoring
   c. Peripheral IV access
   d. Treatment of hypotension with vasopressors
   e. Finger stick blood glucose
   f. Nutrient resuscitation (thiamine before dextrose)
   g. Hypertension may be related to ongoing seizure activity, and termination of status epilepticus often substantially corrects it. Additionally, many agents used to terminate status epilepticus can produce hypotension.
   1b. Emergent initial therapy with benzodiazepines:
   a. Lorazepam 0.1 mg/kg up to 4 mg per dose, may repeat after 5-10 min
   b. Midazolam 0.2 mg/kg IM/IV up to 10 mg
   c. Diazepam 0.15 mg/kg up to 10 mg per dose, may repeat after 5 min
2. Urgent control therapy—antiseizure drugs available in IV formulations:
   a. Fosphenytoin/phenytoin 20 mg PE/kg IV, may repeat bolus of 5 mg/kg IV:
   b. Valproic acid 20-40 mg/kg IV, may repeat bolus of 20 mg/kg IV
   c. Levetiracetam 1000-3000 mg IV
   d. Phenobarbital 20 mg/kg IV, may repeat bolus of 5-10 mg/kg
   e. Lacosamide 200-400 mg IV
   f. Midazolam bolus 0.2 mg/kg IV, followed by 0.05-2 mg/kg/h continuous infusion
3. Refractory therapy–continuous infusion of antiseizure drugs, titrated to either seizure cessation, suppression-burst, or complete suppression on EEG:
   a. Midazolam bolus 0.2 mg/kg IV, followed by 0.05-2 mg/kg/h continuous infusion
   b. Propofol bolus 1-2 mg/kg, followed by 20 mcg/kg/min continuous infusion, titrate up to 30-200 mcg/kg/min
   c. Pentobarbital 5-15 mg/kg, may repeat bolus of 5-10 mg/kg, followed by 0.5-5 mg/kg/h continuous infusion
4. Treat complications.
5. Complications of status epilepticus are numerous and can involve multiple organ systems. In particular, convulsive status epilepticus is associated with cardiac complications such as hypertension and tachycardia, as well as rhabdomyolysis and hyperthermia. Respiratory complications, including respiratory failure, hypoxia, and neurogenic pulmonary edema, may be seen. Status epilepticus is associated with neuronal damage and cerebral edema with increased intracranial pressure, which may require intracranial pressure monitoring and aggressive treatment with hypertonic agents.

From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

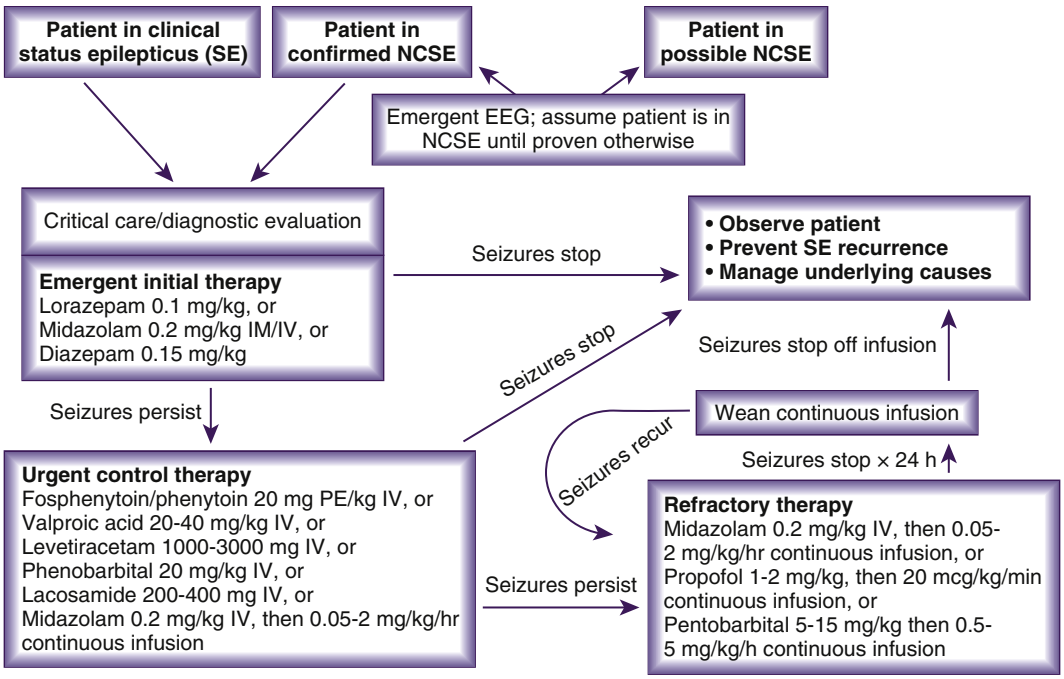

FIG. 1 Management algorithm for status epilepticus. *EEG,* Electroencephalogram; *IM,* intramuscular; *IV,* intravenous; *NCSE,* nonconvulsive status epilepticus; *SE,* status epilepticus. (From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.)

TABLE 4 Treatment Alternatives for Refractory and Super-Refractory Status Epilepticus

	Comments	Adverse Events
Thiopental	Metabolized to pentobarbital	Hypotension Respiratory depression Cardiac depression
Ketamine	Mechanism of action particularly well-suited to treat refractory and super-refractory SE (NMDA receptor antagonist)	High intracranial pressure Hypotension Hallucinations
Inhaled anesthetics	High rate of complications Needs closed system (gas recovery)	Hypotension Infection Paralytic ileus
Ketogenic diet	Relatively safe (no respiratory and cardiocirculatory instability) Slow onset of action Requires skilled dietician	Gastroesophageal reflux Constipation Acidosis Hypertriglyceridemia
Lidocaine	Minor respiratory depression compared with other drugs	Cardiocirculatory instability Possible induction of seizures
Hypothermia	Only transitory control (cannot be a prolonged therapy)	Hypotension Cardiovascular instability Impaired coagulation (bleeding risks)
Resective surgery	Long-term treatment of seizures Not all patients are eligible	Surgical risks

NMDA, N-methyl-D-aspartate; *SE,* status epilepticus.
From Swaiman KF et al: *Swaiman's pediatric neurology, principles and practice,* ed 6, Philadelphia, 2017, Elsevier. See original table for references.

infusions of phenobarbital, midazolam, and propofol are alternatives. Many of these drugs remain under investigation, and superiority of any one agent is not established. Treatment alternatives for refractory and super-refractory status epilepticus are summarized in Table 4.

NONPHARMACOLOGIC THERAPY

None

GENERAL Rx

It is important to find out the etiology of the status epilepticus (e.g., metabolic disturbance, infection). The appropriate treatment/understanding of the underlying cause of the status epilepticus will impact successful treatment.

CHRONIC Rx

- Chronic treatment of status epilepticus depends on underlying etiology.
- Patient with status epilepticus due to epilepsy will need chronic treatment.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Not applicable

DISPOSITION

- Response to treatment depends on the etiology of the status epilepticus.
- When there is no CNS injury as a cause or result of the status epilepticus, the prognosis is good.
- No driving until seizure freedom in accordance with local laws and regulations.

REFERRAL

Status epilepticus is a neurologic emergency; therefore immediate inpatient neurologic consultation is warranted.

PEARLS & CONSIDERATIONS

COMMENTS

- Status epilepticus is a medical emergency that carries a high risk of mortality. Mortality among patients who present in status epilepticus is 15% to 22%. Among those who survive, functional ability will decline in 25% of cases.
- Continuous video EEG is crucial in the treatment of these patients because some of them may not be clinically seizing (convulsing) but electrographically they may still have subclinical repetitive seizures or subclinical status epilepticus.
- In the context of benzodiazepine-refractory convulsive status epilepticus, the anticonvulsant drugs levetiracetam, fosphenytoin, and valproate each led to seizure cessation and improved alertness by 60 min in approximately half the patients, and the three drugs were associated with similar incidences of adverse events.[1]

PREVENTION

Medication compliance is crucial in patients with epilepsy.

PATIENT & FAMILY EDUCATION

- Patients with epilepsy have normal lives.
- The goal of treatment is no seizures and no side effects to medications.
- Patient education and information can be obtained at the Epilepsy Foundation: www.epilepsyfoundation.org
- Pregnant women with epilepsy should visit the Antiepileptic Drug Pregnancy Registry website for information and assistance: www.aedpregnancyregistry.org
- Patients with ongoing seizures are forbidden from driving; check state regulations and laws regarding driving and epilepsy.

BASIC INFORMATION

DEFINITION

Stevens-Johnson syndrome (SJS) is a rare, severe vesiculobullous form of erythema multiforme (EM) affecting the skin, mouth, eyes, and genitalia. SJS is defined as affecting <10% of body surface area (BSA). When it affects 10% to 30% of BSA, it is known as SJS-toxic epidermal necrolysis (TEN) overlap syndrome. TEN affects >30% of BSA. Table E1 provides a classification of SJS and TEN.

SYNONYMS

SJS
Herpes iris
Febrile mucocutaneous syndrome

ICD-10CM CODE
L51.1 Stevens-Johnson syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- SJS affects predominantly children and young adults.
- Male:female ratio is 2:1.
- Prevalence: 1:100,000 for SJS and 1:1,000,000 for TEN

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The cutaneous eruption generally occurs within 4 wk of drug initiation and is generally preceded by vague, nonspecific symptoms of low-grade fever and fatigue (influenza-like symptoms) occurring 1 to 14 days before the skin lesions. Cough is often present. Fever may be high during the active stages. The acute phase of the disease lasts 1 to 2 wk.
- Enlarging red-purple macules (Fig. E1) or papules and bullae generally occur on the conjunctiva, mucous membranes of the mouth (Fig. E2), nares, and genital regions. Lesions rapidly spread to their maximum extent usually within 2 days.
- Corneal ulcerations may result in blindness.
- Ulcerative stomatitis results in hemorrhagic crusting (Fig. E3).
- Nikolsky sign (shearing off of epidermis with pressure on skin) can be present.
- Flat, atypical target lesions or purpuric maculae may be distributed on the trunk or be widespread.
- The pain from oral lesions may compromise fluid intake and result in dehydration.
- Thick, mucopurulent sputum and oral lesions may interfere with breathing.
- Box E1 summarizes features of SJS and TEN.

ETIOLOGY

- Drugs (see Box E2). Upper respiratory tract infections (e.g., *Mycoplasma pneumoniae*) and HSV infections have also been implicated.
- Increased rash of SJS with *HLA-B*1502* and *HLA-B*5801,* HIV, kidney disease, and unconfirmed autoimmune diseases.

TABLE E1 Classification of Stevens-Johnson Syndrome, Toxic Epidermal Necrolysis, and Stevens-Johnson Syndrome–Toxic Epidermal Necrolysis Overlap

	SJS	SJS-Ten	Ten
Lesional morphology	Targetoid lesions, dusky red macules, bullae	Targetoid lesions, dusky red macules, bullae	Targetoid lesions, dusky erythematous macules and plaques; detachment of epidermis
Localization of skin lesions	May be scattered and isolated; may be confluent, especially on the trunk and face	May be scattered and isolated; often confluent	Usually extensive involvement with widespread confluence
Involved skin	<10%	10%-30%	>30%
Biopsy features	More interface dermatitis	Significant interface dermatitis + necrolysis	Predominantly necrolysis
Mucosal changes	Prominent	Prominent	May be less than in SJS
Systemic involvement	Often present	Always present	Always present

SJS, Stevens-Johnson syndrome; *TEN,* toxic epidermal necrolysis.
From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.

FIG. E1 Stevens-Johnson syndrome (SJS). Intensely erythematous macules are nearly confluent on the palms of this boy with SJS from carbamazepine. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E2 Stevens-Johnson syndrome. Purpuric macules became bullous. Note the inflammation of the conjunctivae and lips. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

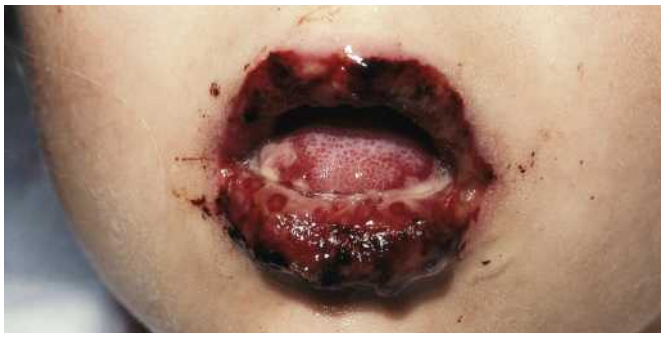

FIG. E3 Stevens-Johnson syndrome. Mucous membrane involvement with severe swelling and hemorrhagic crusting of the lips. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

BOX E1 Features of Stevens-Johnson Syndrome and Toxic Epidermal Necrolysis

- Constitutional
  - Fever
  - Dehydration
- Mucocutaneous
  - Stomatitis with hemorrhagic crusts
  - Oral and genital erosions
  - Dysphagia
  - Purulent conjunctivitis with photophobia
  - Occasionally esophageal and pulmonary mucosal sloughing
  - Dusky erythematous macules, targetoid lesions, bullae, and skin sloughing
- Visceral
  - Lymphadenopathy
  - Hepatosplenomegaly with hepatitis
  - Uncommonly: Pneumonitis, arthritis, myocarditis, and nephritis
- Laboratory abnormalities
  - Increased erythrocyte sedimentation rate (100%)
  - Leukocytosis (60%)
  - Eosinophilia (20%)
  - Anemia (15%)
  - Elevated hepatic transaminase levels (15%)
  - Leukopenia (10%)
  - Proteinuria, microscopic hematuria (5%)

From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.

BOX E2 Most Common Pharmacologic Triggers of Stevens-Johnson Syndrome and Toxic Epidermal Necrolysis

- Allopurinol
- Barbiturates
- Carbamazepine
- Lamotrigine
- NSAIDs
- Penicillins
- Phenytoin
- Sulfonamides

NSAIDs, Nonsteroidal antiinflammatory drugs.
From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxic erythema (drugs or infection)
- Pemphigus
- Pemphigoid
- Urticaria
- Hemorrhagic fevers
- Serum sickness
- *Staphylococcus* scalded-skin syndrome
- Behçet syndrome

WORKUP

- Diagnosis is generally based on clinical presentation and characteristic appearance of the lesions.
- Skin biopsy is generally reserved for when classic lesions are absent and diagnosis is uncertain. Biopsy reveals epidermal necrolysis but cannot distinguish between SJS, TEN, and EM.

LABORATORY TESTS

CBC with differential, cultures in cases of suspected infection

IMAGING STUDIES

Chest x-rays may show patchy changes in patients with pulmonary involvement.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Withdrawal of any potential drug precipitants
- Careful skin nursing to prevent secondary infection

ACUTE GENERAL Rx

- Treatment of associated conditions (e.g., acyclovir for HSV infection, azithromycin for *Mycoplasma* infection)
- Antihistamines for pruritus
- Treatment of the cutaneous blisters with cool, wet Burow compresses
- Relief of oral symptoms by frequent rinsing with lidocaine (Xylocaine Viscous)
- Liquid or soft diet with plenty of fluids to ensure proper hydration
- Treatment of secondary infections with antibiotics
- Corticosteroids: Use remains controversial and there is a clear risk of sepsis; they should be used only in severe cases early in the disease; when used, prednisone 20 to 30 mg bid until new lesions no longer appear, then rapidly tapered
- Topical steroids: May use to treat papules and plaques; however, should not be applied to eroded areas
- Vitamin A: May be used for lacrimal hyposecretion
- Consider IVIG in severe cases

DISPOSITION

- Prognosis varies with severity of disease. It is generally good in patients with limited disease; however, mortality rate may approach 10% in patients with extensive involvement. A severity of illness score known as SCORETEN that incorporates increased glucose level (>252 mg/dl), increased BUN (>28 mg/dl), electrolytes (serum bicarbonate <20 mEq/L), age (>40 yr), immunosuppression (presence of cancer), involvement >10% of BSA, and increased heart rate (>120 beats/min) can be used to calculate mortality risk.
- Oral lesions may continue for several mo.
- Scarring and corneal abnormalities may occur in 20% of patients.

REFERRAL

- Management of SIS is similar to those with extensive burns. Hospital admission in a unit used for burn care is recommended in severe cases.
- Urethral involvement may necessitate catheterization.
- Ocular involvement should be monitored by an ophthalmologist.

SUGGESTED READING

Wetter DA, Camilleri MJ: Clinical, etiologic, and histopathologic features of Stevens-Johnson during an 8-year period at Mayo Clinic, *Mayo Clin Proc* 85(2):131-138, 2010.

BASIC INFORMATION

DEFINITION

Stomatitis is inflammation involving the oral mucous membranes. Mucositis is inflammation and ulceration of the mucous membranes. It is most commonly seen in the mouth but can occur anywhere in the GI, genitourinary (GU), or respiratory tract. It is most often due to side effects of chemotherapy or radiation therapy (Fig. E1) in cancer patients.

SYNONYM

Heterogeneous grouping of unrelated illnesses, each with its own designation(s)

ICD-10CM CODES

A69.0	Necrotizing ulcerative stomatitis
B08.4	Enteroviral vesicular stomatitis with exanthem
B08.61	Bovine stomatitis
B37.0	Candidal stomatitis
K12	Stomatitis and related lesions
K12.0	Recurrent oral aphthae
K12.1	Other forms of stomatitis
K12.30	Oral mucositis (ulcerative), unspecified
K12.31	Oral mucositis (ulcerative) due to antineoplastic therapy
K12.32	Oral mucositis (ulcerative) due to other drugs
K12.33	Oral mucositis (ulcerative) due to radiation
K12.39	Other oral mucositis (ulcerative)
K13.0	Other and unspecified lesions of oral mucosa

PHYSICAL FINDINGS & CLINICAL PRESENTATION

WHITE LESIONS:

- Candidiasis (thrush)
  1. Caused by yeast infection *(Candida albicans)*
  2. Examination: White, curdlike material (Fig. E2) that, when wiped off, leaves a raw, bleeding surface
  3. Epidemiology: Seen in the very young and the very old, those with immunodeficiency (AIDS, cancer), persons with diabetes, and patients treated with antibacterial agents
- Other:
  1. Leukoedema: Filmy opalescent-appearing mucosa, which can be reverted to normal appearance by stretching. This condition is benign.
  2. White sponge nevus: Thick, white corrugated folds involving the buccal mucosa. Appears in childhood as an autosomal dominant trait. Benign condition.
  3. Darier disease (keratosis follicularis): White papules on the gingivae, alveolar mucosa, and dorsal tongue. Skin lesions also present (erythematous papules). Inherited as an autosomal dominant trait.
  4. Chemical injury: White sloughing mucosa.
  5. Nicotine stomatitis: Whitened palate with red papules.
  6. Lichen planus: Linear, reticular, slightly raised striae on buccal mucosa. Skin is involved by pruritic violaceous papules on forearms and inner thighs.
  7. Discoid lupus erythematosus: Lesion resembles lichen planus.
  8. Leukoplakia: White lesions that cannot be scraped off; 20% are premalignant epithelial dysplasia or squamous cell carcinoma.
  9. Hairy leukoplakia: Shaggy white surface that cannot be wiped off; seen in HIV infection, caused by Epstein-Barr virus.

RED LESIONS:

- Candidiasis may present with red lesions instead of the more frequent white. Median rhomboid glossitis is a chronic variant.
- Benign migratory glossitis (geographic tongue): Area of atrophic depapillated mucosa surrounded by a keratotic border. Benign lesion, no treatment required.
- Hemangiomas.
- Histoplasmosis: Ill-defined, irregular patch with a granulomatous surface, sometimes ulcerated.
- Allergy.
- Anemia: Atrophic reddened glossal mucosa seen with pernicious anemia.
- Erythroplakia: Red patch usually caused by epithelial dysplasia or squamous cell carcinoma.
- Burning tongue (glossopyrosis): Normal examination; sometimes associated with denture trauma, anemia, diabetes, vitamin B_{12} deficiency, psychogenic problems.

DARK LESIONS (BROWN, BLUE, BLACK):

- Coated tongue: Accumulation of keratin; harmless condition that can be treated by scraping
- Melanotic lesions: Freckles, lentigines, lentigo, melanoma, Peutz-Jeghers syndrome, Addison disease
- Varices
- Kaposi sarcoma: Red or purple macules that enlarge to form tumors; seen in patients with AIDS

RAISED LESIONS:

- Papilloma
- Verruca vulgaris
- Condyloma acuminatum
- Fibroma
- Epulis
- Pyogenic granuloma
- Mucocele
- Retention cyst

BLISTERS:

- Primary herpetic gingivostomatitis (Fig. E3)
  1. Caused by herpes simplex virus type 1 or, less frequently, type 2
  2. Typical course of herpetic gingivostomatitis: Day 1: Malaise, fever, headache, sore throat, cervical lymphadenopathy; days 2 and 3: appearance of vesicles that develop into painful ulcers of 2 to 4 mm in diameter; duration of up to 2 wk
  3. Recurrent intraoral herpes: Rare; recurrences typically involve only the keratinized epithelium (lips). Table E1 summarizes distinctions between aphthous and herpetic oral ulcers
- Pemphigus and pemphigoid
- Hand-foot-mouth disease: Caused by coxsackievirus group A
- Erythema multiforme
- Herpangina: Caused by echovirus
- Traumatic ulcer
- Primary syphilis
- Perlèche (or angular cheilitis)
- Recurrent aphthous stomatitis (canker sores): Most common oral mucosa lesion; may be associated with many systemic diseases
- Behçet syndrome (aphthous ulcers, uveitis, genital ulcerations, arthritis, and aseptic meningitis)
- Reiter syndrome (conjunctivitis, urethritis, and arthritis with occasional oral ulcerations)
  1. Unknown cause
  2. Solitary or multiple painful ulcers may develop simultaneously and heal over 10 to 14 days. The size of the lesions and the frequency of recurrences are variable.

FIG. E1 Oral mucositis caused by radiation therapy. (From Keefe ZDM, Logan R: Oral complications of cancer and its treatment. In Walsh TD et al [eds]: *Palliative medicine,* Philadelphia, 2008, WB Saunders.)

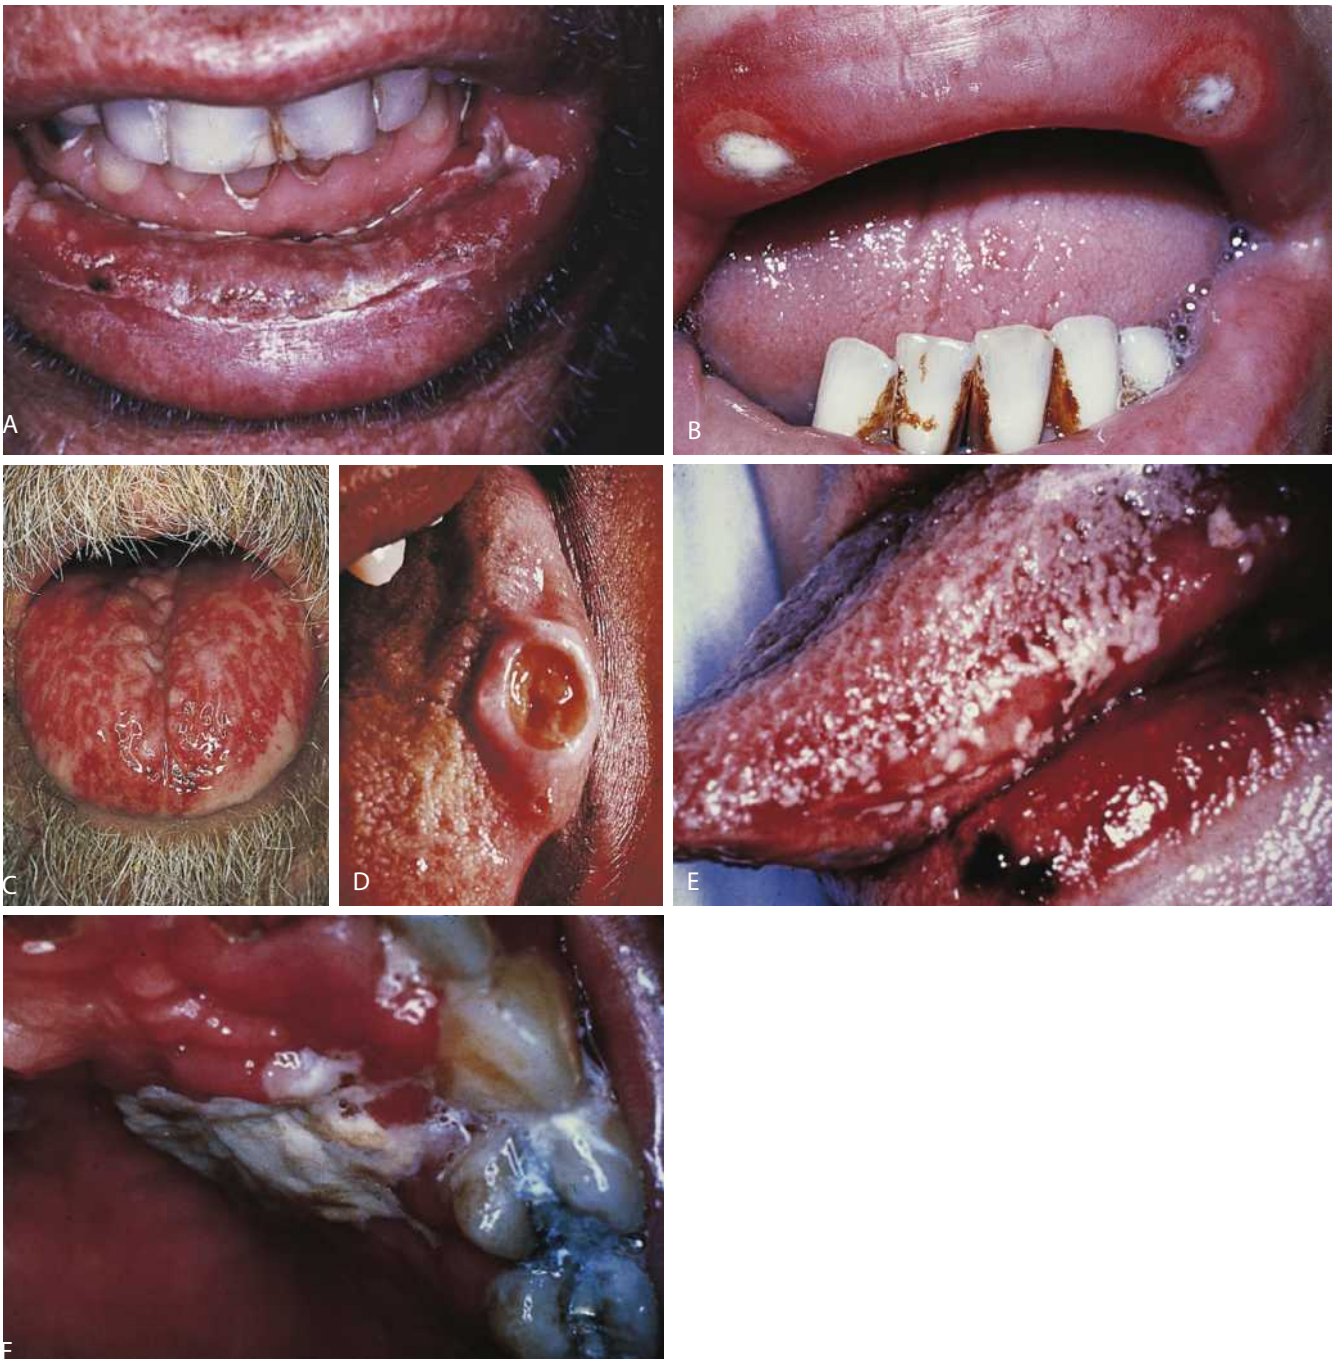

FIG. E2 Stomatitis and mucositis. A, Marked stomatitis in a patient receiving methotrexate. **B,** Aphthous stomatitis related to severe granulocytopenia after chemotherapy. The ulcers may be due to herpes simplex or other infection. **C,** Mucositis in a patient receiving combination chemotherapy for head and neck cancer. **D,** Marked ulcer of the tongue in a 32-yr-old man receiving induction chemotherapy for acute leukemia. **E,** Mucositis of the tongue due to *Monilia* infection (thrush) in a patient receiving corticosteroids for brain metastases. **F,** Marked oral mucositis due to mixed infection in a patient receiving chemotherapy for acute leukemia. (From Skarin AT: *Atlas of diagnostic oncology,* 4 ed, St Louis, 2010, Mosby.)

FIG. E3 Herpetic gingivostomatitis, extensive erosions of the oral mucosa. (James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, WB Saunders.)

TABLE E1 Distinctions between Aphthous and Herpetic Oral Ulcers

Condition	Mucosa	Location
Aphthous ulcers	Unkeratinized	Lateral tongue, floor of the mouth, labial and buccal mucosa, soft palate, pharynx
Herpetic ulcers	Keratinized	Gingiva, hard palate, dorsal tongue

From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

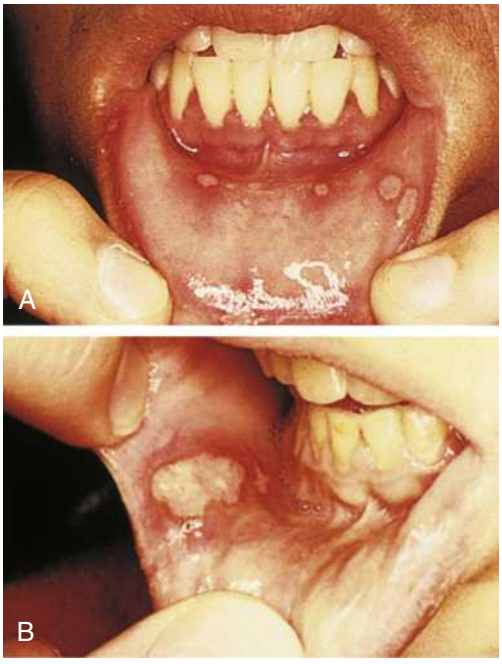

FIG. E4 A, Multiple minor aphthous ulcers. **B,** A major aphthous ulcer. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

DX DIAGNOSIS

WORKUP

- White lesions: Candidiasis (thrush) diagnosis—ovoid yeast and hyphae seen in scrapings treated with KOH culture
- Blisters:
  1. Exfoliative cytology
  2. Viral culture
  3. Immunofluorescence for herpes antigen

RX TREATMENT

White lesions: Candidiasis (thrush) treatment:
- Topical with nystatin or clotrimazole
- Systemic with ketoconazole or fluconazole

Blisters:
- Supportive
- Consider acyclovir

Recurrent intraoral herpes/aphthous ulcerations (Fig. E4): Topical corticosteroids (dexamethasone ointment applied to the identified ulcer tid) or systemic steroids for severe cases.

RELATED CONTENT

Stomatitis (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

Strabismus PTG

BASIC INFORMATION

DEFINITION

Strabismus is a condition of the eyes in which the visual axes of the eyes are not aligned. The misalignment may be constant or intermittent, and it may vary depending on the gaze direction (comitant or incomitant).

SYNONYMS

Esotropia
Exotropia
Heterotropia
Hypertropia
Hypotropia
Restrictive eye movement
Crossed eyes
Walleye
Squint
Lazy eye
Floating eye

ICD-10CM CODES

H50.0	Convergent concomitant strabismus
H50.1	Divergent concomitant strabismus
H50.2	Vertical strabismus
H50.3	Intermittent heterotropia
H50.4	Other and unspecified heterotropia
H50.5	Heterophoria
H50.6	Mechanical strabismus
H50.8	Other specified strabismus
H50.9	Strabismus, unspecified
H51.9	Unspecified disorder of binocular movement

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 2% of the population
PEAK INCIDENCE: Childhood
PREDOMINANT SEX: None
PREDOMINANT AGE: Variable depending on type, but more common in childhood
GENETICS: Most childhood forms suggest polygenic inheritance patterns with variable penetrance, although certain types (i.e., accommodative esotropia, intermittent exotropia) show a definite hereditary predisposition.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Conjugate gaze loss with the eyes fixing independently
- Diplopia in acquired adult-onset strabismus
- Decreased range of eye movements in paralytic and restrictive forms
- Compensatory head posture
- Amblyopia (a decrease in best-corrected visual acuity in an otherwise structurally healthy eye) may occur with untreated strabismus with a childhood onset

ETIOLOGY

- Often obscure in childhood strabismus.
- Many cases of esotropia are infantile, or present in first yr of life
- Accommodative esotropia occurs later, with the peak incidence between 2 and 4 yr of age
- Higher risk with neurologic disease, vision loss, or severe refractive errors
- Orbital or ocular trauma and/or surgery
- Thyroid disorders or other orbital inflammatory disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Evaluation of eye position and movement
- Vision testing
- Refractive errors
- Central nervous system (CNS) tumors
- Orbital tumors
- Brain and CNS dysfunction
- Thyroid disease
- Myasthenia gravis

WORKUP

- Eye examination: Fig. E1 illustrates diagnostic tests that help differentiate between common causes of strabismus. Strabismus is classified according to the type and magnitude of misalignment. Esotropia refers to an inward deviation of the nonfixing eye and exotropia to the outward deviation of the nonfixing eye. Hypertropia is a vertical deviation in which the nonfixing eye is higher, and hypotropia is a vertical deviation in which the nonfixing eye is lower.
- Measurement of deviation: The Hirschberg test (Fig. E2) gives a rough estimate of the angle of a manifest strabismus and is especially useful in young or uncooperative patients or when fixation in the deviating eye is poor.
- Visual field testing.
- MRI or CT to rule out tumors or other intracranial pathology in paralytic strabismus.
- Thyroid function tests in acquired restrictive strabismus.
- Myasthenia gravis workup in acquired, unstable strabismus.

LABORATORY TESTS

- Generally not needed, except in suspected myasthenia gravis where blood testing for acetylcholine receptor antibodies may be helpful, or thyroid function tests in suspected thyroid related eye disease.
- Single-fiber EMG in suspected myasthenia gravis.

IMAGING STUDIES

Necessary only if other neurologic findings are found.

TREATMENT

THERAPY

- Glasses
- Surgery
- Prisms
- Occlusion to relieve diplopia
- Orthoptic exercises
- Botulinum toxin
- Pharmacologic treatment, i.e., pyridostigmine in myasthenia gravis–induced strabismus

CHRONIC Rx

- Glasses
- Prisms
- Ocular occluding devices for intractable diplopia caused by strabismus
- Botulinum toxin

DISPOSITION

Glasses, prisms, and/or surgery may reestablish normal or improved ocular alignment and recover binocular single vision.

REFERRAL

- Early for full evaluation and rehabilitation of functional and cosmetic ocular alignment
- To an ophthalmologist for management (usually)

BASIC INFORMATION

DEFINITION

Ischemic stroke is the sudden onset of a focal neurologic deficit as a result of cerebral ischemia resulting in cell death. The purpose of this chapter is to help the provider make decisions about the management of the acute stroke patient within the first several hours of symptoms; this is the crucial time for definitive treatment interventions.

SYNONYMS

Stroke
Brain attack
Cerebrovascular accident (this is a nonspecific term and should not be used)

ICD-10CM CODES

I63	Cerebral infarction
I63.3	Cerebral infarction due to thrombosis of cerebral arteries
I63.4	Cerebral infarction due to embolism of cerebral arteries
I63.5	Cerebral infarction due to unspecified occlusion or stenosis of cerebral arteries
I63.6	Cerebral infarction due to cerebral venous thrombosis, nonpyogenic
I63.8	Other cerebral infarction
I63.9	Cerebral infarction, unspecified
I67.89	Other cerebrovascular disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- ~795,000 new or recurrent strokes occur each yr in the U.S.
- Stroke is the number five cause of death (165,000 deaths every yr) and the leading cause of long-term disability in the U.S.

PREVALENCE: There are ~4.5 million stroke survivors in the U.S.

RISK FACTORS: Hypertension, dyslipidemia, diabetes mellitus, and smoking are the four major modifiable risk factors. Other risk factors include age, gender, atrial fibrillation (most common cause of cardioembolic stroke), mechanical heart valve, patent foramen ovale, recent myocardial infarction, metabolic syndrome, carotid artery stenosis, vertebral artery stenosis, intracranial artery stenosis, hypercoagulable states, subclinical atrial tachyarrhythmias without clinical atrial fibrillation, sickle cell disease, and obesity.

GENETICS: Multifactorial

PHYSICAL FINDINGS & CLINICAL PRESENTATION

When a patient presents with an acute ischemic stroke acutely, the most important considerations are determination of the time the patient was last known normal, the etiology (ischemic or hemorrhagic), and the severity, because these aspects will determine acute treatment. The time last known normal was when the patient was last seen normal (by themselves or by someone else). If they awoke with the deficits, the time last seen normal was when they went to bed.

Clinical presentation varies with the artery and region of CNS affected. Clinical presentation cannot reliably distinguish between hemorrhagic and ischemic causes, and so imaging must be done. Below is a noncomprehensive list of common stroke syndrome presentations based on the cerebral vascular territory affected. Please note that this list is not comprehensive and that all findings for a particular syndrome may not be listed here.

- Large- to medium-sized arteries:
  1. Dominant middle cerebral artery (MCA): Dominant face and arm > leg weakness and sensory loss with aphasia (expressive, receptive, or both); possible hemianopia
  2. Nondominant MCA: Nondominant face and arm > leg weakness and sensory loss with hemineglect; possible hemianopia
  3. Anterior cerebral artery (ACA): Contralateral leg weakness and sensory loss
  4. Internal carotid artery: Combination of contralateral MCA and ACA
  5. Basilar artery: Typically an acute loss of consciousness preceded by vertigo, nausea, vomiting, and diplopia; quadriparesis or quadriplegia may be seen, including "locked-in" syndrome
  6. Posterior cerebral artery: Unilateral hemianopia; blindness with anosognosia (Anton syndrome) if bilateral
  7. Posterior inferior cerebellar artery: Lateral medullary (Wallenberg) syndrome—ipsilesional loss of pinprick and temperature on the face and contralateral loss of pinprick and temperature on the body; ipsilesional Horner syndrome and ipsilesional palatal weakness with resulting dysphagia, dysarthria. Also with vertigo, nystagmus, ataxia.
- Small arteries: Lacunar syndromes; no cortical signs are present in lacunar syndromes.
  1. Pure motor hemiparesis: Typically due to an ischemic lesion in either the internal capsule or pons.
  2. Pure hemisensory loss: Typically due to an ischemic lesion of the thalamus.
  3. Ataxic hemiparesis: Ataxia out of proportion to the hemiparesis; typically due to an ischemic lesion of either the internal capsule or pons.
  4. Sensorimotor stroke: Typically due to ischemic lesion involving both the thalamus and internal capsule.
  5. Dysarthria–clumsy hand syndrome: Multiple localizations possible but typically the pons; facial weakness, dysarthria, and mild clumsiness and weakness of the hand.

ETIOLOGY

Etiologies include atherosclerosis, cardioembolism, artery-to-artery embolism, small-vessel lipohyalinosis, arteritis, arterial dissection, and vasospasm.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of acute ischemic stroke includes hemorrhagic stroke (intracerebral hemorrhage), subarachnoid or subdural hemorrhage, seizure with postictal paralysis, migraine with hemiparesis or other aura, syncope, hypoglycemia, hypertensive encephalopathy, and conversion disorder.

BOX 1 Immediate Diagnostic Studies: Evaluation of a Patient with Suspected Acute Ischemic Stroke

All Patients
Noncontrast brain computed tomographic scan (magnetic resonance imaging, if available)
Blood glucose level
Serum electrolyte and renal function tests
Electrocardiography
Markers of cardiac ischemia
Complete blood count, including platelet count
Prothrombin time/international normalized ratio
Activated partial thromboplastin time
Oxygen saturation

Selected Patients
CT angiogram head and neck or MR angiogram head and neck
CT or MR perfusion
Hepatic function tests
Toxicology screen
Blood alcohol level
Pregnancy test
Arterial blood gas tests (if hypoxia is suspected)
Chest radiography (if lung disease is suspected)
Lumbar puncture (if subarachnoid hemorrhage is suspected and computed tomography scan is negative for blood)
Electroencephalogram (if seizures are suspected)

CT, Computed tomography; *MR,* magnetic resonance.
From Christensen H et al: Abnormalities on ECG and telemetry predict stroke outcome at 3 months, *J Neurol Sci* 234:99-103, 2005.

TABLE 1 National Institutes of Health Stroke Scale

1A. Level of Consciousness (LOC)	1B. LOC Questions	1C. LOC Commands
0 = Alert 1 = Not alert, but arousable 2 = Not alert, obtunded 3 = Coma	Ask the month and his/her age. 0 = Answers both correctly 1 = Answers one correctly 2 = Answers neither correctly	Open and close the eyes. Open and close the nonparetic hand. 0 = Performs both tasks correctly 1 = Performs one task correctly 2 = Performs neither task correctly
2. Best Gaze (Horizontal)	**3. Visual Fields**	**4. Facial Palsy**
0 = Normal 1 = Partial gaze palsy 2 = Forced deviation or total gaze paresis	0 = No visual loss 1 = Partial hemianopia 2 = Complete hemianopia 3 = Bilateral hemianopia	0 = Normal 1 = Minor paralysis 2 = Partial paralysis (total or near total paralysis of lower face) 3 = Complete paralysis of upper and lower face
5. Motor Arm	**6. Motor Leg**	**7. Limb Ataxia**
Right Arm extended with palms down 90 degrees (if sitting) or 45 degrees (if supine) for 10 s 0 = No drift 1 = Drift; limb drifts down from position and does not hit bed or support in 10 s 2 = Some effort against gravity 3 = No effort against gravity 4 = No movement **Left**	**Right** Leg extended at 30 degrees, always tested supine for 5 s 0 = No drift 1 = Drift; limb drifts down from position and does not hit bed or support in 5 s 2 = Some effort against gravity 3 = No effort against gravity 4 = No movement **Left**	The finger-nose-finger and heel-shin tests 0 = Absent 1 = Present in one limb 2 = Present in two limbs
8. Sensory	**9. Best Language**	**10. Dysarthria**
To Pinprick or Noxious Stimuli 0 = Normal 1 = Mild to moderate sensory loss 2 = Severe to total sensory loss	0 = No aphasia, normal 1 = Mild-to-moderate aphasia 2 = Severe aphasia 3 = Mute, global aphasia, coma	0 = Normal 1 = Mild-to-moderate 2 = Severe (including mute/anarthric due to aphasia) Do not score if intubated.
11. Extinction and Inattention	**Total Score:**	
0 = No abnormality 1 = Present 2 = Profound (two modalities)		

From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

LABORATORY TESTS

- Immediate (Box 1): Complete blood count, metabolic panel that includes blood glucose and renal function, PT/INR, aPTT, troponin I, and urinalysis. Blood glucose is the only test required before initiation of IV tPA
- National Institutes of Health Stroke Scale (Table 1): A brief, focused neurologic examination aimed at providing a numeric estimate of the severity of stroke; can be performed by any health care provider trained in its use; may increase the likelihood of the correct assessment of stroke
- ECG and telemetry monitoring
- Echocardiogram to look for potential cardiogenic source of embolism, infective endocarditis, and intracardiac shunts

IMAGING STUDIES

- Immediate (Fig. 1): Computed tomography (CT) of the head without contrast to rule out hemorrhage.
- CT angiogram of the head and neck is necessary acutely in selected patients if deficits are severe to assess whether there is a thrombus that is amenable to intervention as well as CT head perfusion to assess for the degree of salvageable tissue (Table 2).
- MRI of the brain with stroke protocol to assess the extent of stroke (because CT typically will not show an ischemic stroke for several hours), but it is rarely needed in the hyperacute setting to determine appropriateness of reperfusion strategy.

Cross reference: See "Transient Ischemic Attack" for general workup, which is identical to that for ischemic stroke.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

GENERAL CONSIDERATIONS:

- Airway and breathing should be maintained.
- Supplemental oxygen should be provided to keep the oxygen saturation at ≥92%.
- Pneumatic compression devices or pharmacologic means should be applied to help prevent deep venous thrombosis.
- Avoid any and all oral intake until swallowing is evaluated and found to be unimpaired; this helps to avoid aspiration pneumonia.
- Early mobilization for rehabilitation is desirable.
- Consider neurosurgical intervention for craniectomy in select cases. Typical cases in which craniectomy may be performed include cerebellar ischemia with compression of the brain stem and/or the fourth ventricle as well as large middle cerebral artery ischemia. Available evidence suggests that it may be better to perform early hemicraniectomy (<48 hr) to achieve better outcomes in malignant hemispheric strokes. Decompressive hemicraniectomy has shown good benefit in terms of mortality but not much benefit in terms of disability and functional outcomes.

ACUTE GENERAL Rx

INTRAVENOUS THROMBOLYSIS:

- IV t-PA, or alteplase, is the only medical therapy approved by the U.S. FDA for the treatment of acute ischemic stroke.
- The time window for administration is generally accepted to be within 4.5 hours of symptom onset, although the FDA indication is still within 3 hours. The American Heart Association/American Stroke Association recommends a t-PA administration window of up to 4.5 hours with certain additional exclusion criteria when compared to the 3-hour administration.
- There are strict criteria for the administration of IV t-PA (see Table 3).
- The protocol is weight based, with 90 mg being the maximum allowable dose.
- The risk of brain hemorrhage with IV t-PA is about 6% in stroke patients. The management of suspected intracranial hemorrhage after use of t-PA is summarized in Box 2.
- Endovascular intervention is useful only for large, accessible thrombi. Therefore if a stroke patient is a candidate for IV t-PA, treatment with IV t-PA should be started and then the patient should be assessed for possible endovascular therapy. Table 4 summarizes AHA recommendations for endovascular therapy in patients with acute ischemic stroke.

IMMEDIATE CATHETER CEREBRAL ANGIOGRAPHY FOR ENDOVASCULAR INTERVENTION

(Figs. E2 and E3): Methods available:

- The American Heart Association/American Stroke Association 2018 guidelines now recommend mechanical thrombectomy with a stent-retriever device for highly selected patients who present with large vessel occlusion (LVO) up to 16 hours after last known normal and suggest that it is reasonable up to 24 hours.
  1. IV tPA should be administered in this group if eligible.
  2. All patients should be assessed with CT angiogram head and neck or MRA head and neck for possible LVO if they have an NIHSS of ≥6 or suspicion of a large vessel stroke.
  3. In selected patients with acute ischemic stroke within 6 to 24 hours of last known normal who have LVO on noninvasive angiogram, obtaining a CT perfusion, DW-MRI, or perfusion is recommended

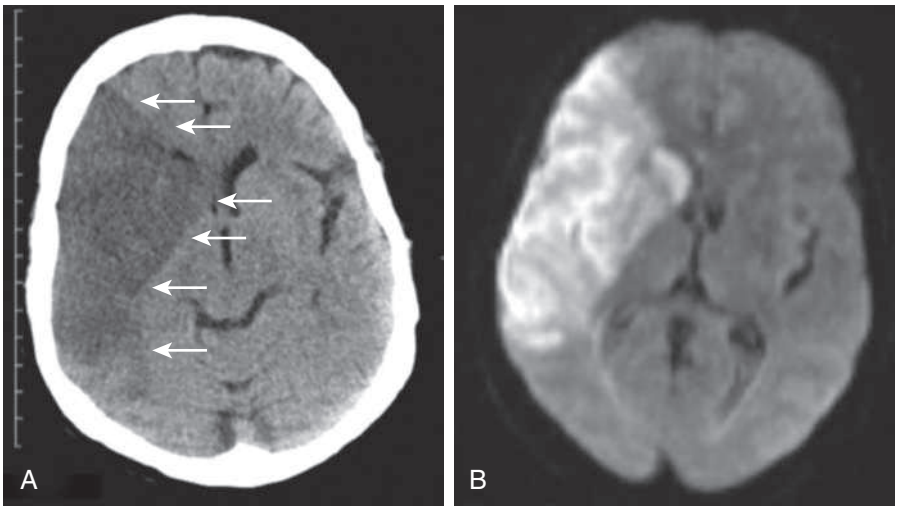

FIG. 1 Large right middle cerebral artery infarct on an unenhanced computed tomographic scan **(A)** and a diffusion-weighted magnetic resonance image **(B).** There is a mass effect, and this patient is at risk for cerebral herniation syndromes.

TABLE 2 Imaging Modalities for Stroke

Imaging Modality	Advantage	Disadvantage
Cerebral catheter angiography	• Allows for the definitive assessment of cerebral circulation (gold standard) • Allows for the deployment of intra-arterial thrombolysis and thrombectomy devices if a thrombus is found • Allows for the assessment of collateral circulation	• Invasive (significant risks) • High cost • Not available at all facilities
Doppler studies	• Noninvasive • May be performed at the patient's bedside	• Can be limited by the patient's body habitus • Operator dependent
Magnetic resonance angiography	• Excellent view of the large arteries of the neck and brain • No contrast material needed	• Cannot be performed in patients who are critically ill, who are unable to tolerate supine positioning, who have a pacemaker or other ferromagnetic hardware, or who are claustrophobic
Magnetic resonance perfusion	• Assesses cerebral hemodynamics • May show ischemic penumbra (i.e., the area of the brain that may be saved by timely intervention)	• Not commonly available • Not well standardized
CT angiography	• Excellent view of the large arteries of the neck and brain • Similar to magnetic resonance angiography with regard to resolution	• Requires intravenous contrast
CT perfusion	• Assesses cerebral hemodynamics • May show ischemic penumbra (i.e., the area of the brain that may be saved by timely intervention)	• Challenging to interpret in some cases • Not routinely available at many facilities • Requires intravenous contrast

CT, Computed tomography.

to aid in patient selection for mechanical thrombectomy.

- Adult patients should receive mechanical thrombectomy with a stent retriever if they present within 6 hours of last known normal with a causative LVO (especially of the internal carotid artery or MCA segment 1 [M1] but reasonable in the setting of a causative MCA segment 2 or 3 [M2/3] or other large vessel cerebral artery) if they were relatively independent before the stroke and have an NIHSS score of ≥6 and an ASPECTS score of ≥6. Treatment needs to be able to be initiated (groin puncture) within 6 hours of symptom onset.
- Patients should receive mechanical thrombectomy with a stent retriever if treatment can be initiated within 16 hours (and possibly up to 24 hours) of last known normal with a large anterior circulation LVO and they meet the DAWN or DEFUSE-3 criteria (a defined mismatch between clinical severity and/or infarct volume compared to the penumbra [tissue at risk]). The number needed to treat to improve functional outcomes is only 2.8, and so patients should be aggressively evaluated for possible treatment.
- Complications can ensue from the endovascular procedure itself, including an intracerebral hemorrhage rate that is similar to that associated with IV t-PA. A recent meta-analysis revealed that among patients with acute ischemic stroke, endovascular therapy with mechanical thrombectomy versus standard medical care with t-PA was associated with improved functional outcomes and higher rates of angiographic revascularization, but no significant difference in symptomatic intracranial hemorrhage or all-cause mortality at 90 days.[1,2]
- Endovascular intervention is typically available only at comprehensive stroke centers.

HYPERTENSION: Elevated blood pressure is common during acute stroke, and it often subsides without specific therapy. In general, hypertension is not treated acutely unless it is extremely high (e.g., >220 mm Hg systolic blood pressure); there is evidence of hypertension-induced organ damage; or thrombolysis is being considered, in which case the blood pressure needs to be reduced (if it can be safely accomplished) to <185/110 mm Hg. It is risky to decrease blood pressure dramatically and quickly in the presence of acute ischemic stroke as it can cause an extension of the infarcted tissue into the ischemic penumbra. A 15% to 25% decrease over the first 24 hours is recommended when more acute lowering is not required.

HYPOTENSION: The presence of systemic hypotension in acute ischemic stroke portends a poor outcome. The cause should be sought, and volume depletion should be corrected with normal saline. Cardiac arrhythmias should be treated. Induced hypertension with vasopressor agents may be useful for select cases with an ischemic penumbra that is at risk, but caution is strongly advised.

HYPOGLYCEMIA: Hypoglycemia can mimic stroke. Prompt assessment of serum glucose level and replacement as necessary are important.

HYPERGLYCEMIA: Hyperglycemia should be treated with sliding scale insulin, taking into consideration the patient's oral intake. The presence of hyperglycemia worsens ischemic stroke outcomes, but recent evidence has not shown that aggressive treatment with an insulin pump improves outcomes.

FEVER: Fever is harmful during acute stroke. Ascertaining and addressing the cause while lowering an elevated temperature is strongly advised.

[1]Only test recommended before initiation of IV rtPA.
[2]Although it is desirable to know the results of these tests before giving a patient tissue plasminogen activator, thrombolytic therapy should not be delayed while awaiting the results unless (1) there is clinical suspicion of a bleeding abnormality or thrombocytopenia; (2) the patient has received heparin or warfarin; or (3) the patient's use of anticoagulants is not known.

TABLE 3 Eligibility Criteria for Acute Thrombolysis in Acute Ischemic Stroke

Eligibility Criteria

- Diagnosis of ischemic stroke causing measurable neurological deficit
- The neurological signs should not be minor and isolated. Caution should be exercised in treating a patient with major deficits
- Onset of symptoms <4.5 hours before beginning treatment
- The neurologic signs should not be clearing spontaneously
- The symptoms of stroke should not be suggestive of subarachnoid hemorrhage
- The patient or family members should understand the potential risks and benefits from treatment

Contraindications for Thrombolysis

- Evidence of intracranial hemorrhage on CT
- Head trauma or prior stroke in previous 3 months
- Myocardial infarction in the previous 3 months
- Gastrointestinal or urinary tract hemorrhage in previous 21 days
- Arterial puncture at a noncompressible site in the previous 7 days
- Major surgery in the previous 14 days
- History of previous intracranial hemorrhage
- Elevated blood pressure (systolic >185 mm Hg and diastolic >110 mm Hg)
- Evidence of active bleeding or acute trauma (fracture) on examination
- Taking an oral anticoagulant or, if taking anticoagulant, INR ≥1.7 is a contraindication
- If receiving heparin in previous 48 hours, aPTT must be in normal range
- Platelet count ≤100,000 mm^3
- Blood glucose concentration ≥50 mg/dl (2.7 mmol/L)
- Seizure with postictal residual neurologic impairments
- CT shows a multilobar infarction (hypodensity >1/3 cerebral hemisphere)

aPTT, Activated partial thromboplastin time; *CT,* computed tomography; *INR,* international normalized ratio.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

BOX 2 Management of Suspected Intracerebral Hemorrhage after Use of Tissue Plasminogen Activator

Discontinue the tPA infusion if it remains in progress.
Obtain noncontrast CT scan of the head stat.
Order PT, PTT, platelet count, fibrinogen level, type and cross-match stat.
In event of hemorrhage, consult hematology and neurosurgery.
Give 6 to 8 units of cryoprecipitate, then 6 to 8 units of platelets.
Administer aminocaproic acid 4 to 5 gm IV over 1 hour, followed by 1 gm PO or IV per hour.
Check fibrinogen every 4 hours and give cryoprecipitate to keep fibrinogen >150 mg/dl.
Monitor blood pressure every 15 min.
Periodically repeat CBC, PT, PTT.
Consider repeat head CT.

CBC, Complete blood cell count; *CT,* computed tomography; *IV,* intravenous; *PO,* oral; *PT,* prothrombin time; *PTT*, partial thromboplastin time; *stat,* immediately; *tPA,* tissue plasminogen activator.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

TABLE 4 AHA Recommendations for Endovascular Therapy in Patients with Acute Ischemic Stroke

Patients should receive endovascular therapy with a stent retriever if they meet all of the following criteria (class I; level of evidence, A):

1. Prestroke modified Rankin score 0 to 1 (functionally independent)
2. Acute ischemic stroke receiving intravenous recombinant tissue plasminogen activator within 4.5 hours of onset according to guidelines from professional medical societies
3. Causative occlusion of the internal carotid artery or proximal middle cerebral artery
4. Age 18 years or older
5. National Institutes of Health Stroke Scale (NIHSS) score of 6 or greater
6. Alberta Stroke Program Early CT Score (ASPECTS) of 6 or greater
7. Treatment can be initiated (groin puncture) within 6 hours of symptom onset

CT, Computed tomography.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

ANTIPLATELET THERAPY: Oral, rectal, or feeding tube administration of aspirin (325 mg/day) within 48 hours of stroke onset is advised to decrease the likelihood of a repeat ischemic stroke. Other oral antiplatelet regimens approved for secondary stroke prophylaxis (e.g., clopidogrel, aspirin plus extended-release dipyridamole) may also be used. Patients who have received t-PA cannot be given antithrombotic or anticoagulant agents within the first 24 hr after administration. In patients with acute ischemic stroke and atrial fibrillation, full dose anticoagulation with heparin infusion or low molecular weight heparin should be avoided in the acute setting, as this could potentially harm the patient by causing symptomatic intracranial hemorrhage, and there is very little evidence to suggest any benefit. However, chronic anticoagulation is indicated after the acute period has passed.

DISPOSITION

Patients with acute ischemic stroke should be cared for in a stroke unit or an intensive care unit. Nurses with skills in stroke care and telemetry monitoring should be routine. Once the patient is stable and the workup is complete, rehabilitation should be arranged.

REFERRAL

Patients with acute ischemic stroke should be transported to a hospital in which providers are skilled in stroke care. Depending on the severity and duration of symptoms, the patient may qualify for immediate endovascular intervention at a comprehensive stroke center, even if he or she is not a candidate for IV tPA. If complications from brain edema develop, further evaluation by a neurosurgeon may be helpful during the acute phase.

PEARLS & CONSIDERATIONS

PREVENTION

- The prevention of acute ischemic stroke depends on the aggressive management of risk factors in individual patients.
- Cross reference: Stroke, secondary prevention.
- Paroxysmal atrial fibrillation is common in patients with cryptogenic stroke. A recent study found that noninvasive ambulatory ECG monitoring for 30 days significantly improved the detection of atrial fibrillation by a factor of >5 and nearly doubled the rate of anticoagulant treatment compared to the standard practice of short-duration ECG monitoring.

PATIENT & FAMILY EDUCATION

Patients and families need to be taught about ways to reduce the risk for recurrent stroke, including lifestyle modifications. Education about rehabilitation goals, when appropriate, should also be accomplished.

The patient was clinically normal. **B,** Thrombi removed from the middle cerebral artery using the Merci clot retrieval system.

BASIC INFORMATION

DEFINITION

Hemorrhagic stroke is the sudden onset of a focal neurologic deficit caused by hemorrhage into or around the brain.

SYNONYMS

Intracerebral hemorrhage (ICH)
Intracranial hemorrhage
Cerebrovascular attack (this is a nonspecific term and should not be used)
The term *subarachnoid hemorrhage* refers to a specific location for hemorrhage, which commonly occurs as a result of a ruptured aneurysm. Please see "Subarachnoid Hemorrhage" for additional information.

ICD-10CM CODES

I61	Intracerebral hemorrhage
I61.0	Intracerebral hemorrhage in hemisphere, subcortical
I61.1	Intracerebral hemorrhage in hemisphere, cortical
I61.2	Intracerebral hemorrhage in hemisphere, unspecified
I61.3	Intracerebral hemorrhage in brainstem
I61.4	Intracerebral hemorrhage in cerebellum
I61.5	Intracerebral hemorrhage, intraventricular
I61.6	Intracerebral hemorrhage, multiple localized
I61.9	Nontraumatic intracerebral hemorrhage, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: There are approximately 795,000 new or recurrent strokes per yr in the U.S., of which approximately 10% are hemorrhagic.[1]

RISK FACTORS:

- Hypertension
- Anticoagulant use
- Thrombolysis
- Alcoholism
- Illicit drug use (e.g., cocaine)
- Cerebral amyloid angiopathy
- Increased age
- African American race
- Low cholesterol, low-density lipoprotein, and triglycerides
- Minuscule increase in absolute risk from antiplatelet therapy
- Questionable effect of chronic kidney disease and selective use of serotonin reuptake inhibitors

GENETICS: Multifactorial

[1]Chatterjee S et al: New oral anticoagulants and the risk of intracranial hemorrhage: traditional and Bayesian meta-analysis and mixed treatment comparison of randomized trials of new oral anticoagulants in atrial fibrillation, *JAMA Neurol* 70(12):1486-1490, 2013.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The presentation varies with the region of the brain that is affected. Table 1 summarizes correlation between levels of brain function and clinical signs. There is no clinical way to distinguish between a primary cerebral hemorrhage and an ischemic stroke; therefore imaging is required. Imaging can also help determine if the diagnosis is ischemic stroke with hemorrhagic conversion versus primary hemorrhage.

The following are common locations for hypertensive hemorrhage:

- Basal ganglia
- Cerebellum
- Pons

Lobar hemorrhage in an older adult is likely due to amyloid angiopathy.

A systematic, detailed examination is necessary when approaching a comatose patient (Box 1). The ICH score is a widely used grading scale to estimate mortality based on CT scan results. Parameters used to calculate the ICH score include Glasgow Coma Scale (GCS) (0 to 2 points) at presentation, patient age ≥80 (1 point), ICH volume ≥30 ml (1 point), presence of intraventricular blood (1 point), and infratentorial origin of blood (1 point). Scores range from 0 to 6, with a score of 0 conferring 0% mortality and a score of 6 with estimated 100% mortality.

ETIOLOGY

- Rupture of vessels
- Aneurysm
- Arteriovenous malformation
- Brain tumor
- Amyloid angiopathy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ischemic stroke
- Seizure with postictal paralysis
- Syncope
- Migraine with hemiparesis
- Conversion disorder

LABORATORY TESTS

- Complete blood count, metabolic panel including blood glucose and renal function, prothrombin time/international normalized ratio, activated partial thromboplastin time, urinalysis, and toxicology screens
- ECG and telemetry monitoring

IMAGING STUDIES

- Immediate: CT scan of the head without contrast is highly sensitive for hemorrhage (Fig. 1).
- CT or MR angiogram to rule out an underlying vascular malformation. CT spot sign on the CTA has been shown to be a reliable early predictor of hematoma expansion.

TABLE 1 Correlation between Levels of Brain Function and Clinical Signs

Structure	Function	Clinical Sign
Cerebral cortex	Conscious behavior	Speech (including any sounds) Purposeful movement Spontaneous To command To pain
Brainstem activating and sensory pathways (reticular activating system)	Sleep-wake cycle	Eye opening Spontaneous To command To path
Brainstem motor pathways	Reflex limb movements	Flexor posturing (decorticate) Extensor posturing (decerebrate)
Midbrain CN III	Innervation of ciliary muscle and certain extraocular muscles	Pupillary reactivity
Pontomesencephalic MLF	Connects pontine gaze center with CN III nucleus	Internuclear ophthalmoplegia
Upper pons		
CN V	Facial and corneal	Corneal reflex-sensory
CN VIII	Facial muscle innervation	Corneal reflex-motor response Blink Grimace
Lower pons		
CN VIII (vestibular portion) connects by brainstem pathways with CN III, IV, VI	Reflex eye movements	Doll's eyes Caloric responses
Pontomedullary junction pressure	Spontaneous breathing Maintained blood pressure	Breathing and blood pressure do not require mechanical or chemical support
Spinal cord	Primitive protective responses	Deep tendon reflexes Babinski response

CN, Cranial nerve; *MLF,* medial longitudinal fasciculus.

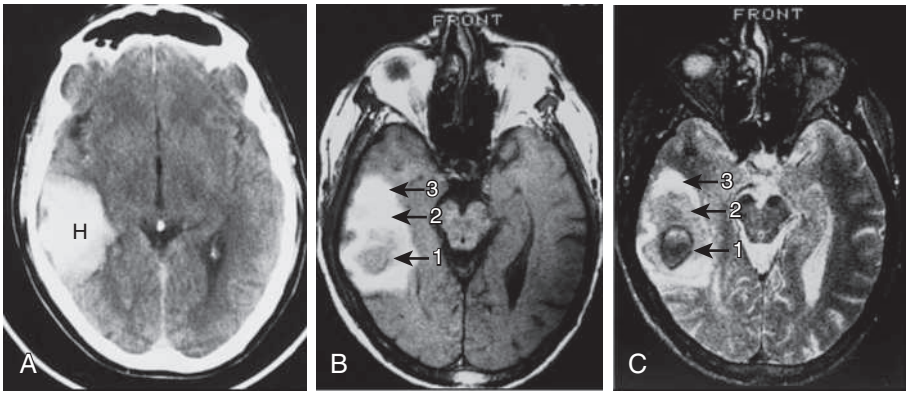

FIG. 1 Hemorrhage. Axial computed tomography image **(A)** demonstrates a large area of acute hemorrhage *(H)* in right temporal lobe. T1-weighted **(B)** and T2-weighted **(C)** magnetic resonance imaging scans demonstrate the hemorrhage in various stages of breakdown. Center of lesion is dark on T1- and T2-weighted images, indicating oxyhemoglobin *(1).* Intermediate zone is bright on T1-weighted image and gray on T2-weighted image, indicating intracellular methemoglobin *(2).* Outer rim is bright on both T1- and T2-weighted images, indicating extracellular methemoglobin *(3).* (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.)

- MRI of the brain with a gradient echo sequence is also highly sensitive for hemorrhage, including intracerebral microhemorrhages that may not be visible with computed tomography scanning. MRI may also help to identify underlying brain tumors or vascular malformations, especially if the bleeding occurs at atypical sites. In the acute setting the MRI may show only the hematoma, but repeat MRI approximately 6 weeks after initial hemorrhage may help exclude these other etiologies.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Urgent neurosurgical evaluation is needed in many cases either for evacuation of the hematoma or for relieving raised intracranial pressure by procedures such as EVD placement or decompressive surgeries.
- Surgery should be performed promptly for cases of cerebellar hemorrhage of >3 cm when the patient is deteriorating clinically, showing brain stem edema or hydrocephalus.
- Surgery for lobar or deep brain clots may be considered for select cases, although the level of evidence for efficacy is not high. Currently, guidelines recommend standard craniotomy for patients with lobar clots >30 ml within 1 cm of the cerebral cortex.
- Recent innovative surgical techniques, such as instillation of thrombolytic agents for intraventricular hemorrhage and minimally invasive surgery for hematoma evacuation, appear to be promising. Clinical trials are currently in progress to assess whether these approaches improve mortality and neurologic outcomes.

ACUTE GENERAL Rx

The cornerstones of medical management of acute intracerebral hemorrhage include:

- Control of hypertension
- Correction of coagulopathy
- Management of elevated intracranial pressure
- Treatment of seizures

HYPERTENSION (BOX 2): Blood pressure should be quickly lowered by 15% and then gradually and safely brought to the individual patient's target range. In theory, this may diminish the expansion of the hematoma. More aggressive control of systolic blood pressure (SBP) to 140 or less in the acute setting has been shown to be safe in clinical trials (INTERACT2 trial) with nonsignificant improvement in outcomes compared to less aggressive BP control (target SBP <180 mm Hg). ATACH 2 studied aggressive blood pressure lowering in patients randomized within 4.5 hr of symptom onset. Patients were randomized to aggressive blood pressure lowering to a target SBP of 110 to 139 mm Hg compared to standard blood pressure lowering to target SBP of 179 to 140 mm Hg. The trial was stopped early because there was no difference in neurological outcome or death, but patients in the aggressive blood pressure lowering arm suffered more kidney injury. Evidence suggests that a more sustained BP control with continuous IV medications might be more beneficial than using intermittent medications resulting in significant BP variability. The most recent guidelines, published in 2015, state that for ICH patients presenting with SBP between 150 and 220 mm Hg and without contraindication to acute BP treatment, acute lowering of SBP to 140 mm Hg is safe and can be effective for improving functional outcome. For ICH patients presenting with SBP >220 mm Hg, it may be reasonable to consider aggressive reduction of BP with a continuous intravenous infusion and frequent BP monitoring.

CORRECTION OF COAGULOPATHY:

- Early hematoma expansion has been associated with poor outcome.
- Protamine sulfate is used to treat cases of heparin-induced intracerebral hemorrhage. Protamine dosage is 1 mg IV for every 100 units of heparin administered in the previous 2 to 3 hours (maximum dose is 50 mg).
- Prothrombin concentrate complex (PCC) is now recommended for reversal of warfarin-associated ICH. FFP may also be used for this purpose, although it carries the disadvantage of administering more volume, potentially leading to complications such as pulmonary edema and slightly longer times to reversal of coagulopathy compared to PCC. Vitamin K should be administered IV along with flash-frozen plasma (FFP)/PCC for sustained effects. Routine use of recombinant factor VII concentrates is not recommended due to insufficient evidence and concern for increased risk of thromboembolic events.
- Idarucizumab (Praxbind) is a humanized monoclonal antibody fragment that can be used for urgent reversal of the anticoagulant effect of the direct thrombin inhibitor dabigatran (Pradaxa).

BOX 2 Suggested Recommended Guidelines for the Treatment of Elevated Blood Pressure in Patients with Spontaneous Intracerebral Hemorrhage

1. SBP of >200 mm Hg or MAP of >150 mm Hg: Consider the aggressive reduction of BP with continuous intravenous infusion, with BP monitoring every 5 min.
2. SBP of >180 mm Hg or MAP of >130 mm Hg with evidence or suspicion of elevated ICP: Consider ICP monitor and reducing BP with intermittent or continuous intravenous medications to keep cerebral perfusion pressure >60 to 80 mm Hg.
3. SBP of >180 mm Hg or MAP of >130 mm Hg without evidence or suspicion of elevated ICP: Consider a modest reduction of BP (e.g., MAP of 110 mm Hg or target blood pressure of 160/90 mm Hg) with intermittent or continuous intravenous medications, and clinically reexamine the patient every 15 min.

BP, Blood pressure; *ICP,* intracranial pressure; *MAP,* mean arterial pressure; *SBP,* systolic blood pressure.
Modified from Broderick J et al: Guidelines for the management of spontaneous intracerebral hemorrhage in adults: 2007 update, *Stroke* 38:2001-2023, 2007.

- Andexanet alfa, a recombinant modified human factor X2 decoy protein, has been effective for reversion of the anticoagulant effect of apixaban (Eliquis), rivaroxaban (Xarelto), and edoxaban (Savaysa).
- Recommendations for thrombolytic-associated intracerebral hemorrhage treatment include the consideration of the infusion of platelets and cryoprecipitate.
- Hemostatic therapy has not been shown convincingly to improve outcomes, despite reducing hematoma expansion. Efforts are under way to identify patients at high risk of early hematoma expansion by using clinical and radiographic information to determine who may benefit from more aggressive hemostatic intervention.
- Platelet transfusion for patients experiencing ICH while on aspirin appears to result in worse outcomes than no platelet transfusion according to the PATCH trial. The odds of death or dependence at 3 mo were significantly higher in the transfused group as compared to the nontransfused group.

ELEVATED INTRACRANIAL PRESSURE: This condition should be treated with a graded approach, which may include the elevation of the head of the bed, analgesia/sedation, hyperventilation, and osmotic therapy. In patients clinically suspected to have elevated ICP or with GCS <8, invasive monitoring of the ICP may be required. If conservative treatment fails to control ICP, external ventricular drain (EVD) placement or other decompressive procedures like craniotomy should be pursued.

SEIZURES: If seizures occur, they should be treated aggressively, including with intravenous medications, if needed. Although widely practiced, routine use of prophylactic antiepileptic medications is not recommended. Continuous EEG monitoring should be employed in patients with suspected seizures or unexplained low levels of consciousness.

SUPPORTIVE TREATMENT:

- Hyperglycemia: A high blood glucose level predicts a worse outcome. Markedly elevated glucose levels should be lowered to <200 mg/dl.
- Antipyretics should be administered for fever in addition to searching for a cause of the fever.
- Care should be taken to avoid hypoxia. Airway and ventilatory management should happen early and concurrently with the primary management of ICH.
- Pneumatic compression devices should be applied to help prevent deep venous thrombosis. Chemical deep venous thrombosis prophylaxis can be started after 48 to 72 hours in most situations once the bleed has been determined to be stable.
- Early mobilization for rehabilitation is desirable.

DISPOSITION

For large hemorrhages or unstable patients, immediate referral to a stroke center

REFERRAL

Patients with hemorrhagic stroke should be transported to a hospital where providers are skilled in the treatment of stroke and cerebrovascular diseases including the availability of neurosurgery services and neurocritical care. Depending on the severity and duration of symptoms, the patient may require neurosurgical intervention.

PEARLS & CONSIDERATIONS

- Outcomes are inversely correlated with hemorrhage size.
- Specific reversal agents may be useful for warfarin-, heparin-, direct oral anticoagulant- (DOAC), or thrombolysis-associated hemorrhage.
- No procoagulant medications have yet been shown to be safe and effective for the mitigation of spontaneous intracerebral hemorrhage in placebo-controlled trials.

PREVENTION

- Prevention depends on the aggressive management of risk factors in individual patients, including hypertension, smoking, alcohol use, and cocaine use.
- DOACs dabigatran, apixaban, rivaroxaban, and edoxaban are uniformly associated with an overall reduced risk of iatrogenic ICH when used for stroke prevention in atrial fibrillation when compared to warfarin. Any of the currently available DOACs can be considered first line for patients at high risk for ICH.

PATIENT & FAMILY EDUCATION

Patients and families need to understand that most patients will not soon achieve functional independence and that rehabilitation will be a long process. Education about avoiding antithrombotic agents should be stressed as appropriate for individual circumstances.

BASIC INFORMATION

DEFINITION

Secondary prevention of stroke involves preventing the recurrence of a cerebral vascular ischemic or hemorrhagic stroke after a primary event (including transient ischemic attack) and early rehabilitation.

SYNONYMS

Brain attack
Stroke
Cerebral thrombosis
Cerebral hemorrhage
Brain infarct

ICD-10CM CODES

I65.2	Occlusion and stenosis of carotid artery
I65.0	Occlusion and stenosis of vertebral artery
I65.9	Occlusion and stenosis of unspecified precerebral artery
I66	Occlusion and stenosis of cerebral artery, not resulting in cerebral infarction
I65.1	Occlusion and stenosis of basilar artery

EPIDEMIOLOGY & DEMOGRAPHICS

Stroke is the fifth leading cause of death in the U.S. and the leading cause of disability. Each yr, there are a total of 795,000 strokes, of which 185,000 are recurrent strokes. Thus, secondary prevention of ischemic stroke remains good treatment strategy. Secondary prevention is specifically targeted toward modifiable risk factors.

RISK FACTORS: Age is the most important nonmodifiable risk factor. Modifiable risk factors include hypertension, hyperlipidemia, cigarette smoking, excessive alcohol consumption, physical inactivity, obesity (i.e., a body mass index of >25 kg/m^2), obstructive sleep apnea, illegal drug use (amphetamines, cocaine), and diabetes mellitus.

GENETICS: Multifactorial and strong family correlation if idiopathic strokes occur in parents <65 yr old.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Stroke can have a varied presentation. Typically, the individual has a sudden definable loss of motor, sensory, visual, or cognitive functions that have a clear time of onset and that are noticed by others or by the individuals themselves.
- Physical findings such as weakness and/or numbness in one limb or on one side of the body, facial droop, visual field loss, or the inability to understand or communicate with others raises one's suspicion of a stroke event.

ETIOLOGY

- Strokes are broadly divided into ischemic or hemorrhagic (i.e., intraparenchymal or subarachnoid hemorrhage). It is impossible to distinguish ischemic from hemorrhagic intracerebral hemorrhage by history alone; therefore imaging is required to confirm stroke subtype.
- Ischemic strokes can be caused by large-vessel atherosclerosis, cardioembolism due to atrial fibrillation or cardiomyopathy, or small vessel disease such as lacunar stroke. Rare causes such as recreational drug use (e.g., cocaine abuse); arterial dissection; and hypercoagulable states need to be considered when ischemic stroke occurs in younger individuals.
- The most common cause of intracerebral hemorrhage is uncontrolled hypertension. Older patients with lobar hemorrhages likely have amyloid angiopathy as the cause of their hemorrhagic stroke. Spontaneous rupture of a brain aneurysm causes subarachnoid hemorrhage.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Seizure and postictal states
- Brain tumor
- Complicated migraine
- Hypoglycemia
- Psychogenic disorder

WORKUP

- Blood glucose level, HBA1c
- Activated partial thromboplastin time, prothrombin time/international normalized ratio complete blood count, and comprehensive metabolic panel
- Fasting lipid panel
- Hypercoagulability tests for young stroke patients with no obvious risk factors

IMAGING STUDIES

- Computed tomography scanning of the head without contrast can differentiate between ischemic and hemorrhagic stroke. MRI of the brain is a more specific and prognostic study.
- Carotid ultrasound and transcranial Doppler are used to detect large-vessel extracranial carotid atherosclerosis but are not useful for visualizing the intracranial vasculature or the posterior circulation. Magnetic resonance angiography (MRA) and computed tomography angiography (CTA) of the head and neck provide imaging of the entire extracranial and intracranial vascular supplying both the anterior and posterior circulations. MRA can be performed without contrast, whereas CTA requires iodinated contrast and may be inappropriate for patients with renal dysfunction.
- Echocardiogram to look for structural abnormalities that could be the source of cardioembolism.
- Heart rhythm monitoring to detect atrial fibrillation. It is rare for an isolated ECG to detect paroxysmal atrial fibrillation that may be the source of the ischemic stroke or transient ischemic attack (TIA). It can even be missed under 24 hr of telemetry in many patients. If a high index of suspicion for a cardioembolic source exists, working with a cardiologist to place a monitoring device should be considered because many cases of paroxysmal atrial fibrillation require more prolonged monitoring for detection.

TREATMENT

The secondary prevention of stroke is targeted toward modifiable risk factors. These include lifestyle modifications such as appropriate diet, exercise, weight loss, and smoking cessation, avoidance of heavy alcohol use, and risk factor modification as listed in the following.

Antiplatelet or Anticoagulant Choice:

All patients with noncardioembolic ischemic stroke or TIA should be on aspirin (50 to 325 mg/day), a combination of aspirin and extended-release dipyridamole, or clopidogrel. Long-term treatment with a combination of clopidogrel and aspirin in secondary stroke prevention when no other pressing medical conditions require their use is no longer recommended due to increased mortality from intracerebral hemorrhage. In some circumstances, short-term treatment with the combination of clopidogrel and aspirin is reasonable in the first 30 to 90 days. Ticagrelor failed to show benefit for secondary stroke prevention compared with aspirin in general, though it may have an improved efficacy in intracranial stenosis. Prasugrel is contraindicated in patients with a history of stroke or TIA. If a patient is already on an antiplatelet drug at the time of stroke or TIA, then consideration of switching to another agent is reasonable, although a holistic approach that includes assessment of compliance with the antiplatelet agent and the extent other risk factors have been controlled is recommended.

PREVENTING STROKE IN SPECIFIC CONDITIONS

- Cardioembolic strokes as a result of nonvalvular atrial fibrillation (AF): All patients with an ischemic stroke secondary to nonvalvular atrial fibrillation would have a CHA2DS2-VASc score of >2, and therefore anticoagulation is recommended. Two first-line drug therapies can be recommended: direct oral anticoagulants (DOACs) such as apixaban, dabigatran, edoxaban, and rivaroxaban; and warfarin with an international normalized ratio (INR) between 2.0 and 3.0. DOACs have been shown to result in a lower rate of intracerebral hemorrhage. Although more expensive than warfarin, DOACs do not require monitoring, do not have the dietary issues associated with warfarin, and have fewer drug-drug interactions. However, patients on enzyme-inducing medications such as phenytoin or HIV patients on protease inhibitors cannot use DOACs. Warfarin is still preferred in patients with marked renal impairment (see specific information available from the FDA about renal impairment and dosing for each DOAC) and in patients with mechanical heart valves or valvular causes of atrial fibrillation. Reversible therapies for some of the DOACs have recently been made available. A patient on a DOAC experiencing a recurrent stroke should only receive tissue plasminogen activator (t-PA) if the patient has been off the medication for at least 48 hr. For patients on warfarin, an INR of less than 1.7 allows for administration of t-PA. There is no evidence that aspirin monotherapy is helpful in reducing cardioembolic events. The Active-A trial suggested that a combination of aspirin and clopidogrel is slightly better than aspirin alone for those unable to tolerate warfarin,

but patients on dual therapy experienced an increased risk of hemorrhagic complications. Because dual-antiplatelet therapy and DOACs have similar rates of bleeding complications but different levels of efficacy for prevention of cardioembolic stroke, the use of aspirin/clopidogrel dual therapy instead of a DOAC is almost never indicated. Furthermore, apixaban and aspirin monotherapies have been shown to have similar rates of bleeding. Thus, patients at risk of bleeding who previously were put on aspirin rather than warfarin could now be prescribed apixaban and experience the same bleeding risk but with actual benefit in terms of stroke risk reduction.

- Cardioembolic strokes as a result of a prosthetic metallic valve: Anticoagulant therapy with warfarin is recommended with a goal INR between 2.5 and 3.5.
- Strokes as a result of large-vessel extracranial atherosclerosis (i.e., symptomatic carotid stenosis): For patients with recent TIA or ischemic stroke and ipsilateral severe (70% to 99%) carotid artery stenosis, carotid endarterectomy (CEA) or carotid stenting is recommended, preferably within 14 days of the event if no contraindication. For patients with recent TIA or ischemic stroke and ipsilateral moderate (50% to 69%) carotid stenosis, intervention is recommended on a case-by-case basis only if the surgeon's perioperative morbidity and mortality rate is <6%.When the degree of stenosis is <50%, there is no indication for CEA. Carotid stenting can be an alternative to CEA in patients with low or average risk of periprocedural complications. In older patients (>70), CEA is associated with better outcomes.
- Symptomatic intracranial atherosclerosis (i.e., cavernous carotid stenosis, basilar stenosis): The symptomatic intracranial artery stenosis stenting trial (SAMMPRIS) demonstrated superiority of aggressive medical management of intracranial atherosclerosis compared with angioplasty and stenting for secondary stroke prevention. Therefore the use of aspirin plus clopidogrel 75 mg daily for 90 days is reasonable in addition to modifiable risk factor management, including high-intensity statin and SBP <140. There is no advantage to using warfarin over aspirin.
- Patent foramen ovale (PFO): The American Academy of Neurology's 2016 guidelines recommend medical therapy with antiplatelets for stroke patients with PFO though recent trials (CLOSE and REDUCE trials) suggest a benefit for PFO closure devices especially in the setting of an atrial septal aneurysm or large interatrial shunt.
- Intracerebral hemorrhage: For immediate management, please refer to the chapter on intracerebral hemorrhage. Anticoagulation or antiplatelet agents should be held for 3 to 4 weeks and can be restarted if there is a compelling indication such as nonvalvular atrial fibrillation. The American Stroke Association/American Heart Association 2014 guideline recommends avoiding long-term anticoagulation (e.g., warfarin, heparin) after spontaneous lobar intracerebral hemorrhage, but antiplatelet therapy (e.g., aspirin, clopidogrel, Aggrenox) may be considered in all cases of intracerebral hemorrhage where there is a definite indication. Consider a neurology consultation in these cases.
- Antiplatelet therapy is recommended in cases of cryptogenic strokes. A consultation with a neurologist should be considered for young stroke patients and for patients with no obvious cause or with stroke from unusual causes (e.g., hypercoagulable states, dissections).

PREVENTING LONG-TERM COMPLICATIONS AFTER A STROKE

- Evaluation by a physical, occupational, and speech therapist will reduce the long-term disability that can follow a stroke event. The American Stroke Association 2014 guideline recommends a multidisciplinary approach to rehabilitation. Studies have shown an improved survival and recovery. Home-based rehabilitation can be considered after discussion with the rehabilitation specialist.
- Depression rates are high after an ischemic stroke, and patients should be screened.

RISK FACTOR MODIFICATION

- Hypertension: Antihypertensive treatment is recommended for both the prevention of recurrent stroke and the prevention of other vascular events in persons who have had an ischemic stroke or a TIA. Absolute target blood pressure level and reduction should be individualized, but a target of <140/90 is reasonable. Blood pressure should be lowered gradually over the first several days after an ischemic stroke to prevent cerebral hypoperfusion and extension of stroke. After a hemorrhagic stroke, blood pressure should be lowered quickly. Lifestyle modifications as listed previously should be included as part of a comprehensive antihypertension treatment plan.
- Diabetes: Uncontrolled hyperglycemia can lead to acceleration of both intracranial and extracranial arteriosclerosis. The goal for the hemoglobin A_{1c} level should be <7%.
  1. In a recent trial involving patients with a history of ischemic stroke or TIA, the risk of stroke or MI was lower among patients who received pioglitazone than among those who received placebo. Pioglitazone was also associated with a lower risk of diabetes but with a higher risk of weight gain, edema, and fracture.
- Hyperlipidemia: For patients with ischemic stroke or TIA with elevated cholesterol levels, statin agents are recommended with a goal low-density lipoprotein <70 mg/dl. The SPARCL study demonstrated that, compared with patients taking placebo, patients taking atorvastatin 80 mg daily experienced a statistically significant reduction in the risk of experiencing a recurrent ischemic stroke.
- Cigarette smoking: Absolute cessation is required. Try to offer pharmacologic therapy or counseling services to the patient. Secondhand tobacco exposure is just as dangerous, so inquire about secondhand exposure.
- Obesity: Weight reduction may be considered for all overweight ischemic stroke and TIA patients to maintain the goal of a body mass index of between 18.5 and 24.9 kg/m^2 and a waist circumference of <35 in for women and <40 in for men.
- Excessive alcohol consumption: Patients with ischemic stroke or TIA who are heavy drinkers should eliminate or reduce their consumption of alcohol. Light to moderate levels of no more than two drinks per day for men and one drink per day for nonpregnant women may be considered.
- Obstructive sleep apnea: A sleep study should be considered due to high prevalence of obstructive sleep apnea in this population and improvement in outcomes.

DISPOSITION

Secondary stroke prevention is a multifaceted approach of lifestyle modification and pharmacologic intervention that is aimed at preventing or limiting disability.

REFERRAL

For complicated recurrent strokes, a referral to a neurologist who specializes in stroke is recommended.

PEARLS & CONSIDERATIONS

The modification of risk factors is the best preventive measure for stroke. Lifestyle modification is a very important aspect of secondary stroke prevention. Always consider the patient's ability to afford the therapy and prescribed follow-up tests. Experience teaches us that patients sometimes will not let us know about their ability to afford therapies unless we inquire.

PREVENTION

Prevention is the goal of treatment, and compliance is the most important factor. Review risk factor reduction and pharmacologic therapy as previously discussed.

Sturge-Weber Syndrome

BASIC INFORMATION

DEFINITION

Sturge-Weber syndrome (SWS) is a sporadic congenital disorder characterized by a dermal capillary malformation (port-wine stain) occurring in association with vascular malformations of the leptomeninges and the eye.

Sturge first described a patient with epilepsy, a facial capillary malformation, and buphthalmos in 1879. Parkes Weber better characterized the pattern and distribution of the characteristic intracranial calcifications. The complete syndrome generally includes the triad of facial dermal capillary malformation (port-wine stain), ipsilateral central nervous system (CNS) vascular malformation (leptomeningeal angiomatosis), and vascular malformation of the choroid of the eye associated with glaucoma. Partial forms have been reported.

SYNONYMS

Sturge (-Weber) (-Dimitri) disease or syndrome
Encephalocutaneous angiomatosis
SWS

ICD-10CM CODE

Q85.8 Other phakomatoses, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

SWS is not a heritable disorder; thus, recurrence is unlikely.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

SWS is characterized by a facial angioma (port-wine stain) and an associated leptomeningeal angioma. These vascular malformations are associated with specific ocular and neurologic abnormalities.

CUTANEOUS MANIFESTATIONS:

- Cutaneous port-wine stain is the most common type of vascular malformation, occurring in 0.3% of newborns. However, only a small number of children with port-wine stains have SWS.
- In SWS, the port-wine stain typically is present on the forehead and upper eyelid (Fig. E1), primarily in the distribution of the first or second division of the trigeminal nerve. Extension of the skin lesion to both sides of the face and the trunk and extremities is common.
- The distribution of the cutaneous angioma influences the risk of an associated leptomeningeal angioma. Leptomeningeal angioma occurs in approximately 90% of cases when the port-wine stain involves both the upper and lower eyelids, compared with 10% when only one eyelid is affected.
- The skin lesion usually is obvious at birth. However, its appearance changes with age and its size increases as the patient grows. In the newborn, the lesion is flat and usually light pink in color. It typically darkens with age to a deep red, port-wine appearance and vascular ectasias develop. The vascular ectasias produce nodularity and superficial blebbing, which lead to overgrowth of the underlying soft tissues and sometimes the bone.
- It may extend to mucosal surfaces with concomitant gingival hypertrophy, which may be even further accentuated in patients being treated with phenytoin for seizures. Some patients exhibit accelerated eruption of teeth.

LEPTOMENINGEAL ANGIOMA:

- Leptomeningeal angioma occurs in 10% to 20% of cases when a typical facial lesion is present. The intracerebral lesion usually occurs on the same side as the port-wine stain. Leptomeningeal angiomatosis seldom occurs without an accompanying facial angioma.
- The parietal and occipital areas are affected most commonly, although any portion of the cerebrum can be involved.
- The pathologic appearance of the leptomeninges includes thickening and discoloration caused by the increased vascularity. The angiomatous tissue typically fills the subarachnoid space in the sulci, and large, tortuous venous structures drain superficially or into the deep venous system. The underlying parenchyma may be atrophic and contain multiple calcific granular deposits. The intraparenchymal calcification may result from chronic tissue hypoxia caused by venous stasis.

OCULAR MANIFESTATIONS:

- Ocular features of SWS include glaucoma and vascular malformations of the conjunctiva, episclera, choroid, and retina.
- The predominant ocular abnormality is glaucoma (increased intraocular pressure), which occurs in 30% to 70% of affected patients. The risk of glaucoma is highest in the first decade. Congenital glaucoma is seen in approximately one half of patients with SWS and presents in newborns with enlargement of the globe *(buphthalmos).* Patients occasionally develop glaucoma as adults. Thus, continued vigilance is needed, even in patients with initially normal intraocular pressure.
- Angioma of the choroid occurs in 30% to 40% of patients with SWS and can lead to increased intraocular pressure. These lesions may be diffuse or localized within the retina.
- Episcleral and conjunctival lesions include anomalous vessels or true angiomata. These may be caused by increased venous pressure in the eye.
- Weber originally noted heterochromia of the iris. The more deeply pigmented iris usually is ipsilateral to the facial angioma. The pigmentation is caused by aggregated melanocytic hamartomata on the anterior surface of the iris.

FIG. E1 A unilateral port-wine stain is present in this man with Sturge-Weber syndrome. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

NEUROLOGIC FEATURES:

- The neurologic features of SWS are progressive and include seizures, focal neurologic deficits, and mental retardation. These disorders occur with variable severity. A small proportion of patients have no neurologic abnormalities.
- The reasons for neurologic progression are uncertain. A possible mechanism is hypoxic-ischemic injury to tissue adjacent to the leptomeningeal angioma. Other proposed mechanisms are venous occlusion and increased venous pressure.

SEIZURES:

- Seizures occur in 80% of patients with SWS and are more common with bilateral than unilateral port-wine stains. Seizures may develop at any age, although they usually start in early childhood.
- Seizures are often the first symptom to appear. Initially, seizures are typically focal but often become generalized tonic clonic. Less often, infantile spasms or myoclonic or atonic seizures are seen. The occurrence of seizures, the age at onset, and the response to treatment affect prognosis. Onset before age 1 yr and poor response to anticonvulsant therapy are associated with a greater likelihood of cognitive impairment.
  1. Hemiparesis: Often develops acutely in conjunction with the onset of seizures. The deficit occurs contralateral to the facial and intracranial lesions. The affected extremity usually does not grow at a normal rate, resulting in hemiatrophy. Some affected children have progressive loss of motor function or have a series of strokelike events.
  2. Intellectual disability: Children with SWS typically develop normally for several months after birth, then manifest developmental delay. However, impairment can be obvious soon after birth, especially in infants with extensive brain involvement. Cognitive function is poorest in patients

with bilateral intracerebral lesions. In one report, only 8% of patients with bilateral leptomeningeal angiomata were intellectually normal.

3. Behavior problems: Are more common in SWS patients than in their unaffected siblings. Higher risk for psychological problems is associated with poorer cognitive function and frequent seizures. However, behavior problems can occur in patients with normal intelligence.
4. Other deficits: Many patients have visual field defects, typically homonymous hemianopia. This is from the involvement of the leptomeningeal angioma with one or both occipital lobes or optic tracts. Hydrocephalus also may occur. This disorder is believed to result from increased venous pressure caused by thrombosis of the deep venous channels or extensive arteriovenous anastomoses.

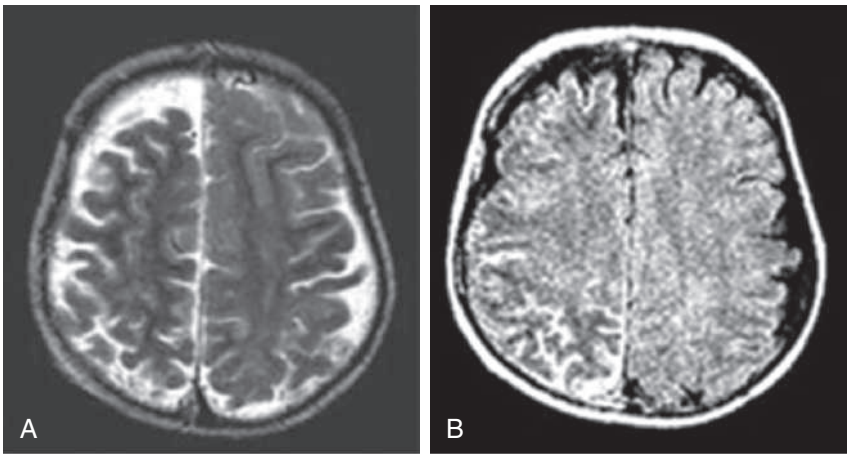

FIG. E2 Axial magnetic resonance image of child with Sturge-Weber syndrome demonstrating atrophy of the left hemisphere and contrast enhancement of the surface of the left hemisphere particularly prominent over the occipital lobe.

ETIOLOGY

The Sturge-Weber syndrome and port-wine stains are caused by a somatic activating mutation in *GNAQ*.[1]

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Klippel-Trenaunay-Weber syndrome (extensive capillary angiomata associated with dysplastic veins involving the limbs and trunk, often with hypertrophy of the affected extremity)
- Von Hippel-Lindau disease (associated with capillary retinal angiomata in contrast to cavernous angiomata seen in SWS)

WORKUP

SWS should be suspected in all patients with facial capillary malformations involving the trigeminal dermatome. At-risk infants should undergo careful physical examination to determine the extent of the malformation.

IMAGING STUDIES

- Most children with facial port-wine stains without an intracranial lesion would be expected to develop normally. Therefore performing neuroimaging studies is helpful to provide prognostic information.
- Plain radiographs of the skull may detect intracranial calcifications, revealing the classic "tram line" appearance, but calcifications are often not present before age 2 yr. Newer radiographic techniques have made plain films obsolete.
- The preferred technique is MRI with gadolinium contrast, which demonstrates the presence of the leptomeningeal angioma and the extent of involvement with brain structures (Fig. E2).
- If MRI is not readily available, cranial CT reliably identifies brain calcification and provides some anatomic information.
- In some cases leptomeningeal involvement may not be detected by neuroimaging during infancy and only becomes apparent later. There is no absolute way to exclude intracerebral lesions during the first yr after birth.

Rx TREATMENT

No specific treatment exists for SWS. The cutaneous, ocular, and neurologic manifestations are treated with mixed success.

ACUTE GENERAL & CHRONIC Rx

Port-wine stain:

- Port-wine stains can be treated by selective photothermolysis with a pulsed-dye laser. Treatment can be further optimized for individual patients so that blanching of the lesion can be accomplished in the fewest possible sessions.
- The response of facial port-wine stains to laser treatment depends on the location and size of the lesion and the patient's age. The greatest decrease in size occurs in the smallest lesions and in the youngest children (<1 yr). The greater success in the youngest patients may reflect treatment before the development of ectasias.
- Complications of laser therapy include scarring and transient hyperpigmentation. Retinal injury can occur if the eyes are not shielded properly.

Glaucoma:

- The development of new medications has improved the medical management of glaucoma in SWS. However, topical treatment often is ineffective in normalizing intraocular pressure. In these cases, the surgical treatment depends on the etiology of the glaucoma.

Seizures:

- Management of seizures in SWS often is difficult. The success of controlling seizures with anticonvulsant medication is variable and unpredictable. Carbamazepine is the recommended antiepileptic of choice. In refractory cases, hemispherectomy or more limited surgical resection of epileptogenic tissue may be beneficial, although risks often outweigh benefits.

REFERRAL

- Initial ophthalmologic evaluation should be performed in the neonatal period because of the risk of congenital glaucoma.
- If the first complete ophthalmologic evaluation is normal, it should be repeated frequently (some authors have suggested quarterly evaluations) for the first 2 yr of life.
- If the examination results remain normal, the vision should be reevaluated at least annually throughout the patient's lifetime.
- Periodic evaluation by a pediatric neurologist is an essential component of the management of SWS.

! PEARLS & CONSIDERATIONS

COMMENTS

- The prognosis for SWS depends on the extent of the leptomeningeal angioma and its effect on the perfusion of the cerebral cortex as well as the severity of ocular involvement.
- Prognosis also is affected by the age of onset of seizures and whether they can be controlled.
- Neurologic function may deteriorate with age. As a result, approximately half of affected adults are impaired, including those who initially were normal.

PATIENT & FAMILY EDUCATION

The Sturge-Weber Foundation is an active support group for patients and families (www.sturge-weber.org).

Stuttering

BASIC INFORMATION

DEFINITION

Stuttering is a neurodevelopmental communication disorder characterized by disruptions in the flow of speech, otherwise known as dysfluencies. Dysfluencies include repetitions of part and whole words, prolongations of sounds, and blocks. Dysfluencies can also be accompanied by physical tension of the speech muscles, secondary characteristics, and feelings and attitudes associated to the stutter.

SYNONYM

Childhood-onset fluency disorder

ICD-10CM CODE
F80.81 Stuttering
DSM-5 CODE
315-35

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Approximately 2% of adults stutter and 5% of children exhibit stuttering. The prevalence of stuttering in the teenage and adult populations is approximately 1% worldwide.
PREDOMINANT SEX AND AGE: During childhood, twice as many boys stutter as girls. More girls than boys recover from stuttering, approximately 80% of those children recover either with or without treatment. Male-to-female ratio is 3:1 in older children and adults, and 1.5:1 in very young children (30 to 48 months). Stuttering is three to four times more common in males than in females. Stuttering begins around 18 mo and puberty but mostly between 2 and 5 yr of age.
GENETICS: Studies show higher rates of stuttering within families of those who stutter and a higher concordance for stuttering in identical twins compared to fraternal twins; 30% to 60% of individuals who stutter have a family history of stuttering.
RISK FACTORS: Presence of other speech or language disorders, family history of stuttering, onset after 3.5 yr of age, male sex, and stuttering over 6 months in duration. Adult onset may occur after head injury, neurological disorder, or intense fear.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Stuttering usually presents between the ages of 2 and 5, when normal language development begins and children are transitioning from using simple phrases to more complex sentences. Characteristics of stuttered speech include repetitions of part or whole words (e.g., I I I like to go go go shopping), prolongations (e.g., I lllllike to go shopping), and interjections (e.g., I like to, um, go shopping).
- Stuttering is often accompanied by behaviors and feelings that can lead to significant impairment in academic, social, and occupational spheres. Affected individuals show fear and embarrassment around speech and may avoid speaking in some situations. People who stutter develop secondary behaviors that can be broken into two categories: escape behaviors and avoidance behaviors.
- Differentiating stuttering from normal developmental dysfluency is important. Normal dysfluency occurs in many children, is self-limited, and does not need treatment. It is characterized by occasional stuttering events (6-8/100 words and 2/100 syllable and word repetitions) and brief stuttering events (<0.5 second). The child does not seem concerned about the dysfluency, the disrupted speech tends to come and go based on whether the child is tired, excited, or talking about new or complex topics, and speech is typically tension-free with no secondary behaviors. Stuttering, in contrast, occurs in more speaking situations (15/100 words and 9/100 syllable and word repetitions), the stuttering event is of longer duration (>0.5 s), there are signs and symptoms or tension and secondary behaviors, and there is an emerging awareness of difficulties.

ETIOLOGY

- Findings in twin studies consistently demonstrate strong phenotype inheritance in identical twins compared with fraternal twins.
- Researchers at present are utilizing genome-wide association study (GWAS) and functional genome-wide association study (fGWAS) techniques to better understand specific genetic variations that are associated with stuttering. Genes on chromosomes 9, 10, 12, 13, and 18 have been associated with stuttering, although the functions of these candidate genes have not been reliably determined.
- Stuttering might be related to abnormal elevations of cerebral dopamine activity.
- Brain imaging studies show distinct differences in sensorimotor integration centers in the brains of those who stutter compared to controls. It is unclear whether observed brain differences are part of the pathophysiology of stuttering or arise as an adaptation to prolonged stuttering.
- Although parents do not cause their child's stuttering, a critical, impatient, or interrupting speech environment can lead to worsening stuttered speech. Early emotional trauma and other parenting behaviors can also be substantial factors to onset and worsening of stuttering in children.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Stuttering is classified as developmental, neurogenic, or psychogenic.
- Normal fluency development is different from stuttered speech and occurs between 2 and 6 yr of age. Examples of normal dysfluencies include whole-word and phrase repetitions, revising sentences, pauses filled with "filler words" (e.g., um, ah, uh), silent pauses such as hesitations, and infrequent, single, part-word repetitions.
- Developmental stuttering, known simply as stuttering, is the most common form of speech dysfluency and usually presents in the preschool yrs.
- Neurogenic stuttering, by contrast, is much less common and can be caused or exacerbated by a traumatic brain injury, infection, or cerebrovascular accident and is typically acquired after childhood. Neurogenic stuttering may be an early diagnostic sign of a neurological problem.
- Psychogenic stuttering, like neurogenic, is much less common than developmental stuttering. It is a later-onset disorder and has an identifiable precipitant, which most often takes the form of an emotional stressor/injury as opposed to a physical injury.
- Psychogenic stuttering can be differentiated from developmental stuttering because those affected with it are usually not overly concerned about their dysfluency. Additionally, unlike developmental stuttering, psychogenic stuttering does not improve when the affected individual sings or recites something in a chorus, or when the auditory processing of his own voice is blocked, i.e., with ear plugs or when music is played in headphones.
- Differentiating neurogenic stuttering from developmental and psychogenic stuttering can be more challenging, especially in cases where no clear history exists or no visual evidence is available. Similar to individuals with psychogenic stuttering, some with neurogenic stuttering do not notice their stuttered speech and thus can appear unconcerned about it. Other times, affected individuals do notice their speech dysfluency and are troubled by it, as is the case in developmental stuttering.
- History of developmental stuttering is a risk factor for the emergence of neurogenic stuttering; that is, successfully treated developmental stuttering can reemerge after a brain injury.

WORKUP

- Diagnostic information should include a client interview, review of developmental and family history, assessment of speech fluency (context, quality, frequency, duration, and presence of secondary behaviors), and assessment of the emotional, cognitive, and attitudinal impact of stuttering on academic, social, or occupational spheres. Formalized assessments can also be used to assess the frequency and duration of stuttered speech, physical concomitants associated with dysfluencies, and the naturalness of the individual's speech.
- A parent or caregiver interview should be completed to assess the parental response to the child's stuttering (intrusive/critical/anxious vs. accepting/patient/calm).
- A full physical exam should be conducted with special attention to the mental status exam and neurologic exam.
- No laboratory tests or imaging studies are indicated unless neurogenic stuttering is suspected.

- Evaluation by an audiologist for a formal hearing assessment to rule out hearing loss or discrimination disorder may be beneficial in some cases.
- The use of a cognitive neuroscience approach to understanding the relationships between language processing and stuttering has utilized electrophysiological measures of time-locked brain activity–event related potentials.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Typically, provided by a speech language pathologist. Medications are not first-line treatment.
- Requires a synergistic approach of speech and language, attitudinal, and environmental factors. Speech and language factors include fluency-shaping mechanisms, stuttering modification tools, delayed auditory feedback devices, message therapy (primarily for preschoolers), and the Lidcombe approach (parental use of operant conditioning techniques for children under the age of 6 yr). Attitudinal factors include treatment of self-esteem, locus of control, and assertiveness as they are related to the stutter. Lastly, treatment of environmental factors include any stimuli, events, or ongoing characteristics that have an impact on the person's fluency level, cultural factors, and the family component.
- The above therapies help the person who stutters reduce fear about stuttering and produce speech more easily. Treatment focuses on helping the child speak slower and decreasing physical tension and struggle. Families are encouraged to create an atmosphere of acceptance and calm for their child to speak, including providing the children full attention when they are speaking, turn taking, decreased demands to speak, repetition of utterances, and modeling of slow speech.

ACUTE GENERAL Rx

- Clinical trials have not resulted in effective, practical medication options for the treatment of stuttering. Smaller-scale trials and case studies have been conducted with a variety of agents, including clonidine, antipsychotics, and GABA-A partial agonists. Clonidine was found to be ineffective in reducing speech dysfluency. A recent double-blind, randomized, placebo-controlled study of the GABA-A partial agonist pagoclone showed a significant reduction in speech dysfluency. A phase III trial of this medication not been conducted.
- Case reports of deep brain stimulation of the ventral intermediate nucleus of the thalamus have shown some reduction in speech dysfluency in adults with severe stuttering.

DISPOSITION

Research suggests that as many as 70% of children who stutter will outgrow it without therapy; however, if a child has been stuttering for more than 1 yr, the likelihood of outgrowing it without therapy is reduced.

REFERRAL

Children with severe stuttering should be referred immediately to a speech-language pathologist for further evaluation and treatment. Those presenting with a mild stutter should be referred if stuttering continues for longer than 6 to 8 wk or if there is significant concern by the parent or child.

Stye (Hordeolum) PTG

BASIC INFORMATION

DEFINITION

A hordeolum is an acute inflammatory process affecting the eyelid and arising from the meibomian (posterior) or Zeis (anterior) glands. It is most often infectious and usually caused by *Staphylococcus aureus*. When infection involves the meibomian glands, it is called meibomianitis.

SYNONYMS

Hordeolum
Meibomianitis

ICD-10CM CODES

H00.011	Hordeolum externum right upper eyelid
H00.012	Hordeolum externum right lower eyelid
H00.013	Hordeolum externum right eye, unspecified eyelid
H00.014	Hordeolum externum left upper eyelid
H00.015	Hordeolum externum left lower eyelid
H00.016	Hordeolum externum left eye, unspecified eyelid
H00.019	Hordeolum externum unspecified eye, unspecified eyelid
H00.021	Hordeolum internum right upper eyelid
H00.022	Hordeolum internum right lower eyelid
H00.023	Hordeolum internum right eye, unspecified eyelid
H00.024	Hordeolum internum left upper eyelid
H00.025	Hordeolum internum left lower eyelid
H00.026	Hordeolum internum left eye, unspecified eyelid
H00.029	Hordeolum internum unspecified eye, unspecified eyelid

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Unknown
PREVALENCE (IN U.S.): Unknown
PREDOMINANT SEX: No gender predilection
PREDOMINANT AGE: May occur at any age
NEONATAL INFECTION: Rare in the neonatal period
PEAK INCIDENCE: May occur at any age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Abrupt onset with pain and erythema of the eyelid
- Localized, tender mass in the eyelid (Fig. E1)
- May be associated with blepharitis
- External hordeolum: Points toward the skin surface of the lid and may spontaneously drain
- Internal hordeolum: Can point toward the conjunctival side of the lid and may cause conjunctival inflammation

ETIOLOGY

- 75% to 95% of cases are caused by *S. aureus*, which includes MRSA strains.
- Occasional cases are caused by *Streptococcus pneumoniae*, other streptococci, gram-negative enteric organisms, or mixed bacterial flora.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Eyelid abscess
- Chalazion
- Allergy or contact dermatitis with conjunctival edema
- Acute dacryocystitis
- Herpes simplex infection
- Cellulitis of the eyelid

LABORATORY TESTS

- Generally, none are necessary.
- If incision and drainage are performed, specimens should be sent for bacterial culture.

TREATMENT

NONPHARMACOLOGIC THERAPY

External stye (eyelash follicle): Usually responds to warm compresses and will drain spontaneously.

ACUTE GENERAL Rx

- Systemic antibiotics generally not necessary for an external stye.
- For internal stye, use hot packs *plus* oral dicloxacillin 500 mg qid × 7 days. If suspecting methicillin-resistant *Staphylococcus aureus* (MRSA), use trimethoprim-sulfamethoxazole DS bid in place of dicloxacillin. In patients with hospital-acquired infection, consider linezolid 600 mg PO bid.
- For external stye, topical erythromycin ophthalmic ointment applied to the lid margins two to four times daily until resolution may be helpful in some cases.
- Incision and drainage: Rarely needed but should be considered for progressive infections.

DISPOSITION

- Usually sporadic occurrence
- Possible relapse if resolution is not complete

REFERRAL

- For evaluation by an ophthalmologist if visual acuity or ocular movement is affected or if the diagnosis is in doubt
- For surgical drainage if necessary

PEARLS & CONSIDERATIONS

COMMENTS

Seborrheic dermatitis may coexist with hordeolum.

Subarachnoid Hemorrhage PTG

BASIC INFORMATION

DEFINITION

Subarachnoid hemorrhage (SAH) is defined as hemorrhage into the subarachnoid space surrounding the brain. This can be either nontraumatic (typically due to cerebral aneurysm rupture) or traumatic in nature. Here we will focus upon nontraumatic subarachnoid hemorrhage. Box 1 describes the Hunt and Hess clinical classification of patients presenting with aneurysmal SAH.

SYNONYMS

Subarachnoid bleed
SAH

ICD-10CM CODES

I60	Subarachnoid hemorrhage
I60.1	Subarachnoid hemorrhage from middle cerebral artery
I60.2	Subarachnoid hemorrhage from anterior communicating artery
I60.3	Subarachnoid hemorrhage from posterior communicating artery
I60.4	Subarachnoid hemorrhage from basilar artery
I60.5	Subarachnoid hemorrhage from vertebral artery
I60.7	Subarachnoid hemorrhage from intracranial artery, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Nontraumatic: 6 to 8 cases/100,000 persons per yr.

PREDOMINANT SEX: Women aged >55 yr were found to have a 25% greater risk of developing SAH compared with men of the same age.

PREDOMINANT AGE: The mean age at onset is 55 yr.

PEAK INCIDENCE: Most aneurysmal SAH occurs in people who are between the ages of 55 and 60 yr.

GENETICS:

- First-degree relatives have a 5 to 12 times greater risk of developing SAH compared with the general population.
- Autosomal dominant polycystic kidney disease is known to be associated with cerebral aneurysms in 8% of cases; screening is recommended in families with this condition. in which one family member has experienced a ruptured aneurysm.
- Collagen vascular diseases such as Marfan syndrome, Ehler Danlos syndrome have also been implicated in the formation of aneurysms.

RISK FACTORS: Although genetics seem to play a factor in SAH, lifestyle factors are more important for determining overall risk. These risk factors include smoking, hypertension, oral contraception, pregnancy, and amphetamine/cocaine use.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The primary symptom is a sudden, severe headache in >90% of cases. About 50% have a headache that is classically described as the "worst headache of my life" and reaches maximal intensity within 1 min—the so-called thunderclap headache. This headache may be associated with nausea/vomiting, neck pain, seizure, or complete loss of consciousness.
- 30% to 60% of patients report a history of headaches during the weeks preceding the actual hemorrhage event. These are most likely sentinel bleeds that represent microhemorrhages.
- Altered mental status and coma may result from the direct effect (hemorrhagic mass effect), but more likely is the result of acutely increased intracranial pressure.
- A posterior communicating artery aneurysm may present as oculomotor (cranial nerve III) palsy, typically involving the pupillary fibers, even in a nonruptured setting.
- Table 1 describes the World Federation of Neurologic Surgeons clinical classification of SAH.

ETIOLOGY

- A ruptured saccular (berry) aneurysm is the most common cause of spontaneous SAH (75% to 80% of spontaneous SAH).
- Idiopathic SAH, also known as angiogram-negative SAH, accounts for 5% to 20% of spontaneous SAH. In these cases, no angiographic cause of the hemorrhage is found. This entity is also known as benign perimesencephalic SAH and is thought to occur due to rupture of venous plexus in the cisterns surrounding the brain stem.
- Other causes of spontaneous SAH include arteriovenous malformations, bleeding into preexisting tumors, vasculitis, and rarely reversible cerebral vasoconstriction syndrome, cerebral venous sinus thrombosis, or intracranial cerebral artery dissection.
- Cocaine abuse, sickle cell anemia, coagulopathies, and pituitary apoplexy can also result in SAH.
- Trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intracerebral hemorrhage as a result of spontaneous rupture of intracerebral arteries or arterioles (rather than arteries passing through the subarachnoid space) due to hypertension or amyloid angiopathy, as well as trauma, intratumoral bleed, ischemic stroke with hemorrhagic conversion, cerebral venous sinus hemorrhage associated with venous sinus thrombosis, mycotic aneurysm rupture.
- Other headache syndromes: Thunderclap headaches due to reversible cerebral vasoconstriction syndrome (often with recurrent thunderclap headaches), migraine headache, sexual headache, cough headache, exertional headache, secondary causes including, but not limited to, pituitary apoplexy or acute hydrocephalus.

WORKUP

IMAGING STUDIES:

- Computed tomography (CT) of the head (Fig. E1) shows hemorrhage in more than 95% of cases, especially during the acute phase (i.e., 24 to 48 hr) after the onset of bleeding. Box 2 describes the Fisher grade of SAH on initial CT (Fisher III being associated with highest risk of vasospasm). About 3% to 5% of SAH may be missed on initial CT of the head. MRI brain, specifically FLAIR sequence, is helpful in detecting subarachnoid blood if clinically suspected.
- Lumbar puncture should be performed in all cases of suspected SAH with "normal CT of the head" between 6 and 12 hours after the onset of the headache for highest yield. The following suggest SAH:
  1. An RBC count of more than 100,000/m^3 in tubes 1 AND 4. This is to differentiate

BOX 1 Hunt and Hess Clinical Classification of Subarachnoid Hemorrhage

I	Asymptomatic or mild headache and neck stiffness
II	Moderate to severe headache and neck stiffness ± cranial nerve palsy
III	Mild focal deficit, lethargy, or confusion
IV	Stupor, moderate to severe hemiparesis
V	Deep coma, extensor posturing

From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.

TABLE 1 World Federation of Neurologic Surgeons Clinical Classification of Subarachnoid Hemorrhage

Grade	Glasgow Coma Scale	Motor Deficits
I	15	Absent
II	13-14	Absent
III	13-14	Present
IV	7-12	Present or absent
V	3-6	Present or absent

BOX 2 Fisher Grade of Subarachnoid Hemorrhage on Initial Computed Tomography

1	No blood detected
2	Diffuse or vertical layers <1 mm thick
3	Localized subarachnoid clot and/or vertical layers ≥1 mm thick
4	Intraparenchymal or intraventricular clot with diffuse or no SAH
Modified Fisher CT Rating Scale	
1	Minimal or diffuse thin SAH without IVH
2	Minimal or thin SAH with IVH
3	Thick cisternal clot without IVH
4	Thick cisternal clot with IVH

CT, Computed tomography; *IVH,* intraventricular hemorrhage; *SAH,* subarachnoid hemorrhage.
From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.

from a traumatic tap in which there will be a drop in RBC count from tube 1 to 4.
2. Presence of xanthochromia or bilirubin in the cerebrospinal fluid.
3. SAH can also be excluded by the following two criteria: CSF RBC count <2000 × 10^6/L and no xanthochromia.

- CT angiogram of the brain (Fig. E2).
- Digital subtraction angiography with 3D processing when indicated is the gold standard for diagnosis of etiology in subarachnoid hemorrhage.

LABORATORY TESTS

- Basic laboratory values, including CBC, chemistry panel, prothrombin time, partial thromboplastin time, and platelet count.
- Serum troponin to evaluate for severe cardiac stress; elevated troponins indicate cardiac ischemia secondary to catecholamine surge and is associated with poor outcome.
- Patients with SAH are prone to developing cerebral salt wasting, resulting in hyponatremia. Sodium levels should be monitored frequently.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Airway, breathing, and circulation
- Once stabilized, good neurologic exam
- Cerebrospinal fluid (CSF) drainage may be required for patients who develop hydrocephalus and increased intracranial pressure. It is also recommended for patients with Hunt and Hess grade 3 or higher.

ACUTE GENERAL Rx

- Critical care management: Initial management strategies are geared toward stabilizing the patient and preventing re-hemorrhage and hydrocephalus. Re-hemorrhage occurs within 72 hours in up to 23% and is associated with very high mortality rates.
- Blood pressure control: Tight blood pressure control is paramount before securing the aneurysm to protect against re-rupture. Blood pressure control can be achieved with the use of antihypertensive infusions such as intravenous nicardipine. A systolic blood pressure of less than 140 mm Hg is recommended. Placement of arterial line is recommended. After securing of the aneurysm, liberalization of blood pressure parameters is the standard.
- Intracranial pressure control: Raised intracranial pressure occurs in more than 50% of patients with subarachnoid hemorrhage secondary to hydrocephalus, cerebral edema, cerebral infarction or other causes. Insertion of a ventricular catheter to treat acute hydrocephalus and maintain intracranial pressure <20 mm Hg can be lifesaving. Patients who are unable to be weaned may require permanent CSF diversion.
- In cases of aneurysmal SAH, treatment focuses on occlusion/exclusion of the aneurysm to prevent rebleeding. The most common treatment methods are:
  1. Microsurgical clipping: Performed through a craniotomy by placing a clip around the neck of the aneurysm
  2. Endovascular coiling (Fig. E3): Performed via digital subtraction angiography; it consists of deploying platinum coils inside the aneurysm or stents in the parent artery to cause thrombosis of the aneurysmal sac. Most aneurysms currently are treated endovascularly.
- Vasospasm: Cerebral vasospasm is a morbid complication leading to cerebral ischemia, disability, and death after SAH. It typically develops between day 4 and 14 (but may occur up to day 21) after the hemorrhage, and it reaches a peak on day 6 to 8. Treatment strategies include:
  1. Current medical therapy for vasospasm focuses upon hypertension, with typical mean arterial pressure goals of 90 to 100 (after aneurysm is secured) and with euvolemia instead of hypervolemia, as the latter was found to lead to significant cardiopulmonary and hemodynamic complications. "Triple H" therapy—*H*ypertension, *H*ypervolemia, and *H*emodilution—was originally employed to maintain cerebral perfusion, but it has fallen out of favor due to its many complications.
  2. Nimodipine (60 mg q4h or 30 mg q2h if blood pressure is low) has been shown to improve outcomes if it is administered between days 4 and 21 after the hemorrhage, even if it does not significantly reduce the amount of vasospasm detected on angiography.
  3. Intraarterial therapies such as intraarterial calcium channel blockers and balloon angioplasty may be employed as needed.
- Seizures occur in about 3% of patients during the acute phase; use of prophylactic antiepileptics is controversial and not recommended, but patients presenting with seizures should be treated appropriately with anticonvulsants.
- Pain control: Use short-acting and less-sedating medications (e.g., codeine, low-dose morphine).
- Monitor and treat for cerebral salt wasting and any other electrolyte abnormalities or anemia.
- Maintain normothermia.

CHRONIC Rx

- Management of reversible risk factors mentioned above (smoking, hypertension, drug use)
- Management of neurologic disability through physical therapy and rehabilitation

DISPOSITION

- SAH is often associated with a poor outcome with a death rate between 30% and 40%; 10% to 15% of patients die before they reach the hospital though outcomes have been improving over the past two decades.
- Almost half of those who survive hospitalization have cognitive impairments or disability that affect their lifestyles.

REFERRAL

Patients should be managed in a cerebrovascular center that maintains capacity to perform open surgical and endovascular procedures, with a critical care unit experienced in caring for neurosurgical patients.

PEARLS & CONSIDERATIONS

COMMENTS

- "Thunderclap" headaches should be considered SAH until proven otherwise and evaluated by CT of the head with/without LP. MRI FLAIR sequence is also a helpful modality.
- All SAH should be managed in a critical care setting (preferably neurocritical care unit) with neurosurgical care available.
- Measures to prevent rebleeding include adequate control of blood pressure and aneurysm treatment with the use of coiling or clipping.

PREVENTION

Controlling some of the modifiable risk factors, especially smoking and blood pressure, may help to decrease the risk of aneurysmal rupture.

PATIENT & FAMILY EDUCATION

- SAH is a devastating condition, with most survivors developing significant neurologic or cognitive deficits. A good support system and an adequate physical and cognitive rehabilitation program may prove useful to survivors.
- Screening may be useful for patients with two or three first-degree relatives with SAH.

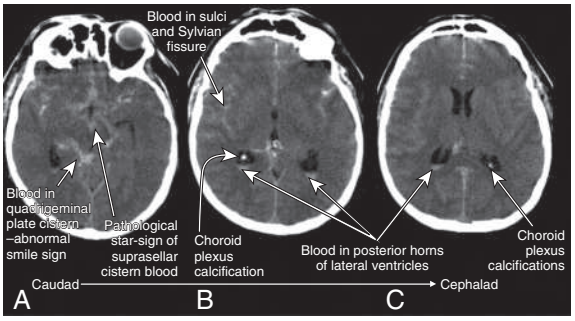

FIG. E1 Subarachnoid hemorrhage (SAH), noncontrast computed tomography (CT), brain windows. Acute SAH appears white on noncontrast CT brain windows. **A** through **C,** nonconsecutive axial slices, progressing from caudad to cephalad. In this case of diffuse SAH, note the presence of subarachnoid blood filling the sulci, as well as extending into the cisterns, Sylvian fissures, and even lateral ventricles. In **A,** blood *(white)* fills the suprasellar cistern. This star-shaped structure is normally filled with cerebrospinal fluid (CSF) *(black).* The quadrigeminal plate cistern is normally a smile-shaped black crescent, filled with CSF, but in this case is filled with blood. Extremely bright calcifications in the choroid plexus of the posterior horns of the lateral ventricles are common, normal findings—do not mistake these for hemorrhage. Note their similarity in density to bone of the calvarium. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

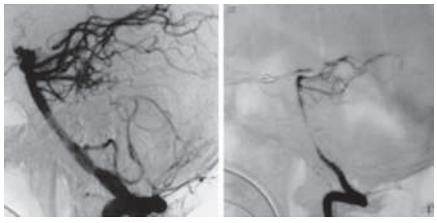

FIG. E2 Baseline angiogram obtained shortly after subarachnoid hemorrhage (*left*) and repeat angiogram obtained 7 days later (*right*) showing severe vasospasm of basilar artery, with reduced distal flow. (From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.)

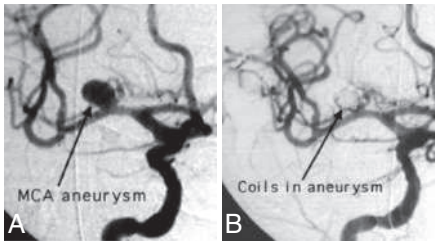

FIG. E3 Angiogram demonstrating middle cerebral artery aneurysm before **(A)** and after placement of detachable coils to thrombose the aneurysm **(B).** (From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.)

Subclavian Steal Syndrome

BASIC INFORMATION

DEFINITION

Subclavian steal syndrome is an occlusion or severe stenosis of the proximal subclavian artery leading to decreased antegrade flow or retrograde flow in the ipsilateral vertebral artery and neurologic symptoms referable to the posterior circulation.

SYNONYM

Proximal subclavian (or innominate) artery stenosis or occlusion

ICD-10CM CODE

G45.8 Other transient cerebral ischemic attacks and related syndromes

EPIDEMIOLOGY & DEMOGRAPHICS

- Similar to that of other manifestations of atherosclerosis (coronary artery disease, cerebrovascular disease, or peripheral vascular disease)
- Affects middle-aged persons (men somewhat younger than women on average) with arteriosclerotic risk factors, including family history, smoking, diabetes mellitus, hyperlipidemia, hypertension, and sedentary lifestyle

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms:

- Many patients are asymptomatic.
- Upper-extremity ischemic symptoms: Fatigue, exercise-related aching, coolness, numbness of the involved upper extremity.
- Neurologic symptoms are reported by 25% of patients with known unilateral subclavian steal. These include brief spells of:
  1. Vertigo
  2. Diplopia
  3. Decreased vision
  4. Oscillopsia
  5. Gait unsteadiness

These spells are only occasionally provoked by exercising the ischemic upper extremity (classic subclavian steal). Left subclavian steal is more common than right, but the latter is more serious.

- Posterior circulation stroke related to subclavian steal is rare.
- Innominate artery stenosis can cause decreased right carotid artery flow and cerebrovascular symptoms of the anterior cerebral circulation, but this is uncommon.

Physical findings:

- Delayed and smaller volume pulse (wrist or antecubital) in the affected upper extremity
- Lower blood pressure in the affected upper extremity
- Supraclavicular bruit

NOTE: Inflating a blood pressure cuff will increase the bruit if it originates from a vertebral artery stenosis and decrease the bruit if it originates from a subclavian artery stenosis.

ETIOLOGY & PATHOGENESIS

Etiology:

- Atherosclerosis
- Arteritis (Takayasu disease and temporal arteritis)
- Embolism to the subclavian or innominate artery
- Cervical rib
- Long-term use of a crutch
- Occupational (baseball pitchers and cricket bowlers)

Pathogenesis: The vertebral artery originates from the subclavian artery. For subclavian steal to occur, the occlusion must be proximal to the takeoff of the vertebral artery. On the right side, only a small distance separates the bifurcation of the innominate artery and the takeoff of the vertebral artery, explaining why the condition occurs less commonly on the right side. Occlusion of the innominate artery must affect right carotid artery flow.

DIAGNOSIS

The carotid arteries should be evaluated at least noninvasively in all cases.

DIFFERENTIAL DIAGNOSIS

- Posterior circulation transient ischemic attack or stroke
- Upper-extremity ischemia:
  1. Distal subclavian artery stenosis or occlusion
  2. Raynaud phenomenon
  3. Thoracic outlet syndrome

WORKUP

- Noninvasive upper-extremity arterial flow studies
- Doppler sonography of the vertebral, subclavian, and innominate arteries
- Arteriography, magnetic resonance arteriogram (Fig. 1)

TREATMENT

- In most patients the disease is benign and requires no treatment other than atherosclerosis risk factor modification and aspirin. Symptoms tend to improve over time as collateral circulation develops.
- Vascular surgical reconstruction requires a thoracotomy; it may be indicated in innominate artery stenosis or when upper-extremity ischemia is incapacitating.

AUTHOR: **Fred F. Ferri, MD**

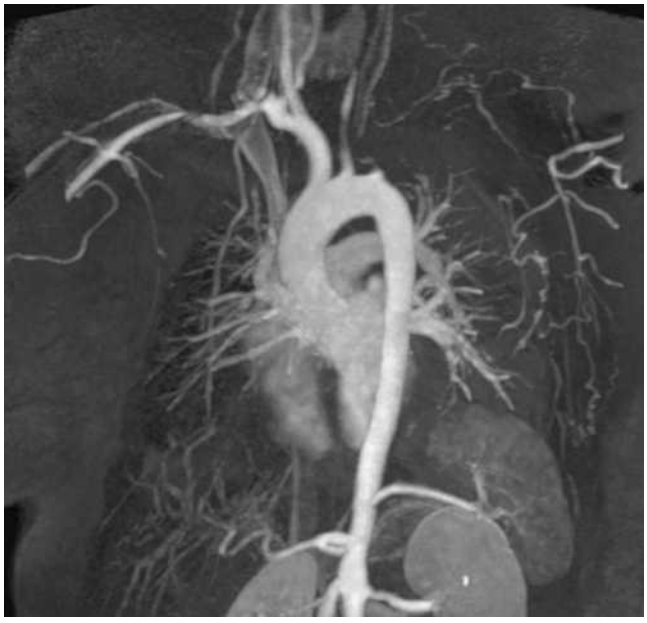

FIG. 1 Magnetic resonance arteriogram demonstrating diffuse moderate stenosis of the proximal left common carotid and proximal occlusion of the left subclavian artery coming off the aortic arch with development of an extensive collateral network. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

BASIC INFORMATION

DEFINITION

Subclinical brain infarct (SBI) is defined as the presence of infarcted brain tissue without a history of transient neurologic or strokelike symptoms. It was initially identified in clinicopathological studies. The advent of neuroimaging has made it easier to detect and characterize. On a CT scan, it often is described as areas of hypodensity resembling cerebrospinal fluid (CSF). On a brain MRI, it is defined as well circumscribed, usually circular lesions greater than 3 mm, iso to hypointense on T1 and hyperintense on T2 weighted images.

SYNONYMS

SBI
Silent brain infarction
Covert brain infarction

ICD 10-CM CODE
I63.9 Cerebral infarction, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Annual incidence 2% to 4% per year over the age of 50 with incidence rates increasing with age
PEAK INCIDENCE: Peak incidence occurs in the aging population and those with prior history of a stroke or a transient ischemic attack (TIA). The incidence of SBIs can be as high as 19% annually in people with prior history of transient ischemic attacks and as high as 23% in those undergoing carotid endarterectomies.
PREVALENCE: The overall prevalence of SBIs ranges from 8% to 62% depending on the population being studied. It increases with age and cardiovascular risk factors.
GENETICS: Genetic polymorphisms of endothelial nitric oxide synthase (eNOS), vascular endothelial growth factor (VEGF), methylenetetrahydrofolate reductase (MTHFR), and protein kinase Cη (PRKCH) have been associated with increased risk of SBIs.
RISK FACTORS: Age, hypertension, metabolic syndrome, carotid artery disease, chronic kidney disease, coronary artery disease, heart failure, hyperhomocysteinemia, obstructive sleep apnea and other cardiovascular risk factors

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- By definition, a subclinical brain infarct is silent or asymptomatic when it occurs in isolation. It tends to occur in multiples in at-risk populations, and the effect is clinically apparent when episodes accumulate.
- The condition is associated most significantly with cognitive decline, and it increases the risk of dementia as well as functional decline.
- The presence of SBIs also doubles the risk of ischemic stroke or TIA, and multiple SBIs are associated with more severe, subsequent ischemic stroke.

ETIOLOGY

The etiology of an SBI is very similar to any other infarct. That is, it occurs due to cessation of blood supply to a particular area of the brain. SBIs are subclinical and asymptomatic likely due to the fact that they occur in noneloquent areas of the brain or are small enough to allow neural plasticity to take over.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dilated perivascular spaces
Chronic symptomatic infarction
Chronic cerebral microvascular disease

WORKUP

- CT scan though the sensitivity is low
- SBIs can be readily identified on MRI using T1 and T2 sequences.

LABORATORY TESTS

There are no laboratory tests to detect SBIs, but elevated low-density lipoprotein and c-reactive protein are associated.

IMAGING STUDIES

Brain CT scan or MRI

TREATMENT

Aggressive control of vascular risk factors to reduce subsequent risk of stroke, cardiovascular disease, and dementia

PEARLS & CONSIDERATIONS

COMMENTS

- A subclinical brain infarct in isolation has no clinical manifestations, but accumulation of these lesions can lead to cognitive decline and increase the risk of dementia.
- SBIs increase subsequent risk of stroke more than 50%. Hence, when these are detected in asymptomatic individuals, they may point toward unidentified vascular risk factors. Identification and modification of these risk factors may have significant benefit.

PATIENT & FAMILY EDUCATION

None

BASIC INFORMATION

DEFINITION

A subdural hematoma (SDH) is a collection of blood or blood products between the brain and dura mater. Subdural hematomas can be acute (ASDH) or chronic (CSDH) and vary significantly in presentation and treatment.

SYNONYM

Subdural hemorrhage

ICD-10CM CODES

I62.01 Acute subdural hematoma
I62.03 Chronic subdural hematoma
S06.5 Traumatic subdural hemorrhage

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- The exact incidence of ASDH is unknown, but it is commonly seen in patients with head injury.
- CSDH is most common in the elderly with an estimated incidence of 1.72 to 13.1 per 100,000.

PREVALENCE: Unknown

PREDOMINANT AGE AND SEX:

- Peak incidence of CSDH is in the eighth decade and is notably higher in males.
- ASDHs usually present in the trauma setting and can happen in all age groups. In particular, shaken baby syndrome can be associated with SDH in the infant population.

RISK FACTORS:

- Trauma and antithrombotic therapy are the most common risk factors for ASDH and CSDH.
- Brain atrophy secondary to advanced age and alcoholism are common risk factors, especially with the coagulopathy/thrombocytopenia seen in chronic alcoholics.
- Intracranial hypotension associated with CSF shunts or leaks is uncommon but can result in acute or chronic SDH.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms vary on the basis of acuity, size, and location. Acute traumatic SDHs are often seen in traumatic brain injury patients, and their Glasgow Coma Scale may vary according to the extent of brain injury, size of hematoma, and associated compression. When associated with a midline shift (i.e., >5 mm), they can cause signs of cerebral herniation (e.g., ipsilateral pupil dilation, contralateral weakness) requiring prompt surgical evacuation.
- Patients with CSDH may present with diverse nonspecific symptoms such as headaches, confusion, gait disturbance, incontinence, aphasia, hemiparesis, transient ischemic attack-like symptoms, and seizures.

ETIOLOGY

SDH is usually the result of shearing and tearing of a bridging vein between the brain parenchyma and the dura mater. Other causes of bleeding into the subdural space include contusion, extension of parenchymal hemorrhage. In the setting of spontaneous SDH, other vascular abnormalities, such as arteriovenous (AV) malformation, aneurysm, and dural AV fistula, should be kept in mind.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cerebrospinal fluid (CSF) hygromas, abscesses, and tumor infiltrations

WORKUP

- Clinical assessment: Patient history, including medications, specifically anticoagulants/antiplatelets; alcohol abuse; recent trauma; cancer; and recent bacterial infections
- Neurologic examination: Glasgow Coma Scale, cranial nerves, motor/sensory exam CT head

LABORATORY TESTS

Assessment of the patient's coagulation status including CBC with platelet count, prothrombin time, partial thromboplastin time, and liver function test (especially with a history of alcoholism or liver failure)

IMAGING STUDIES

CT head (Fig. 1): Demonstrates the classic crescentic collection between the brain and inner table. For comatose and trauma patients, include a cervical spine CT scan. ASDH is usually hyperdense, whereas a CSDH is usually hypodense on noncontrast CT. Contrast is only needed if there are concerns about tumor or infection.

TREATMENT

- Correction of underlying coagulopathy, if present (e.g., warfarin/ASA/clopidogrel reversal).
- Admission for monitoring in the setting of acute SDH.
- The majority of SDH can be managed without surgery in awake patients with normal neurologic examinations.

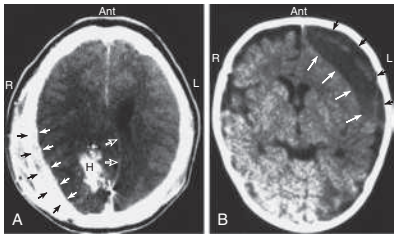

FIG. 1 A, Noncontrast computed tomography scan of an acute subdural hematoma shows a crescentic area of increased density in the right posterior parietal region between the brain and the skull *(black and white arrows).* An area of intraparenchymal hemorrhage *(H)* is also seen. **B,** A chronic subdural hematoma for a different patient is shown. There is an area of decreased density in the left frontoparietal region *(arrows)* that effaces the sulci, compresses the anterior horn of the left lateral ventricle, and shifts the midline somewhat to the right. (From Mettler FA [ed]: *Primary care radiology,* Philadelphia, 2000, WB Saunders.)

- Medical management of CSDH using antifibrinolytic therapy with tranexamic acid 650 mg per day has shown promising results, although a small, randomized, placebo-controlled trial showed no statistically significant difference.
- Seizure prophylaxis with phenytoin or levetiracetam for seven days should be considered in almost all cases, as there is underlying injury to the brain tissue associated with acute subdural hematoma. The irritative effects of blood products on the brain can also contribute to seizures, in both acute and chronic subdural hematomas. If seizures do occur, video EEG monitoring should be instituted and aggressive treatment undertaken.

NONPHARMACOLOGIC THERAPY

Surgical treatment is indicated in:

- ASDHs measuring >10 mm in thickness with a midline shift >5 mm on CT scan and a compromised neurologic status (Glasgow Coma Scale <9, pupillary asymmetry or fixation) should be immediately evacuated.
- In CSDH with a mass effect, a clear change in the neurologic examination from baseline, and/or enlargement of the hematoma size, evacuation via craniotomy or burr hole should be considered.

DISPOSITION

Depending on the size and location of the SDH and the examination of the patient, observation can range from the ICU to outpatient management. When observation of the patient is considered, clinical examinations should be serially performed. Patient baseline and follow-up clinical examinations are more important than CT scan findings.

REFERRAL

Neurosurgical and operative consultation should be made available.

PEARLS & CONSIDERATIONS

COMMENTS

- Many elderly patients have small CSDHs or hygromas. Unless these are associated with seizures or clinical or radiographic progression, they are usually not emergent and usually do not require neurosurgical intervention. Recurrence after surgical management for CSDH is common.
- SDHs in elderly patients can have a mixed hyperdense and hypodense appearance on noncontrast CT scan; this finding is suggestive of subdural membranes and chronic components.

PATIENT & FAMILY EDUCATION

Individuals with SDHs are at higher risk for seizure, so surveillance is important.

RELATED CONTENT

Subdural Hematoma (Patient Information)

AUTHORS: **Farhan A. Mirza, MD,** and **Justin F. Fraser, MD**

BASIC INFORMATION

DEFINITION

A localized accumulation of infected fluid, often encapsulated, located under the diaphragm and may also involve the liver and spleen

SYNONYMS

Subdiaphragmatic abscess
Infradiaphragmatic abscess

ICD-10CM CODES

K65.1 Peritoneal abscess
K68.11 Postprocedural retroperitoneal abscess

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Not well known but intraabdominal abscess occurs in 1% to 2% of all cases of abdominal surgery. It increases to 10% to 30% in cases with preoperative perforation of a hollow viscus, spillage of fecal material into peritoneum, or intestinal ischemia.

RISK FACTORS:

- Abdominal surgery, especially with accidental viscus perforation
- Peptic ulcer perforation
- Appendiceal perforation
- Diverticulitis with perforation
- Mesenteric ischemia with bowel infarction
- Abdominal trauma especially penetrating trauma
- Foreign body ingestion with subsequent viscus perforation

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Constitutional symptoms include:
  1. Fever, malaise, or chills
  2. Cough, increased respiratory rate with shallow or grunting respiration
  3. Shoulder-tip pain on affected side (referred pain)
- Physical findings can include:
  1. Dullness to percussion on affected side
  2. Diminished or absent breath sounds on affected side
  3. Tenderness over the eighth to eleventh ribs

ETIOLOGY

Infection is usually polymicrobial: Aerobic gram-negative rods, most commonly *Escherichia coli, Klebsiella* species, *Enterobacter* species, and *Pseudomonas aeruginosa,* and gram-positive cocci: *Streptococcus viridians,* enterococci and *Staphylococcus aureus,* and anaerobes (found in 60% to 70% of cases) such as *Bacteroides fragilis* and *Clostridia* species.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Liver abscess
- Subhepatic abscess
- Lesser sac abscess
- Empyema of the lung
- Diaphragmatic hernia

WORKUP

Should be started in patients with recent abdominal surgery (weeks to months) with the constitutional symptoms and physical findings mentioned above

LABORATORY TESTS

- Complete blood count with differential may show an elevated white blood count with left shift
- Blood cultures may be positive in up to 50% of the cases
- Gram stain and culture, aerobically and anaerobically, of any aspiration procedure

IMAGING STUDIES

- Plain x-ray films can suggest the location of the abscess in about 50% of the cases and can demonstrate elevation of the hemidiaphragm and/or subphrenic air-fluid level
- Ultrasonography and CT (Fig. 1) are more sensitive
- Other options include leukocyte tagged with gallium 67 and indium 111 scans and MRI

TREATMENT

Includes source control with either percutaneous drainage or surgery and intravenous antibiotics:

- Percutaneous drainage via interventional radiology:
  1. Percutaneous drainage with catheter placement remains the preferred treatment despite the fact that the subphrenic location can be problematic for imaging-guided percutaneous drainage.
  2. Approaches include subcostal approach or intercostal approach. The intercostal approach is associated with a higher risk for pleural complications, but these tend to be minor.
  3. Radiographic modalities used include ultrasonography, CT, and fluoroscopy.
  4. Complications of drainage procedures can include pleural effusion, pneumothorax, or empyema.
- Surgery: May be required in recurrence of abscess or due to multiple abscesses not amenable to percutaneous drainage procedure
- Antibiotics: Broad-spectrum antibiotics should be used to cover Gram-negative rods, Gram-positive bacteria, and anaerobes until cultures are resulted and should be continued at least 4 to 7 days after adequate drainage procedure. Examples include:
  1. Piperacillin/tazobactam 3.375 g IV q6h or 4.5 g IV q8h
  2. Meropenem 1 g IV q8h or imipenem 0.5 to 1 g IV q6h
  3. Ciprofloxacin IV 400 mg IV q12h plus IV metronidazole 500 mg IV q8h for penicillin allergic patients

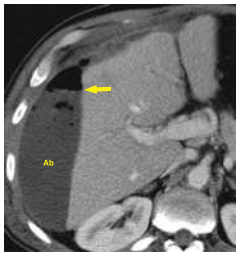

FIG. 1 Subphrenic abscess. A postoperative abscess *(Ab)* is seen as a fluid collection between the diaphragm and the liver. Mass impression on the liver is evidence of fluid loculation. An air–fluid level *(arrow)* is evident, caused by gas-producing *Escherichia coli.* This abscess was successfully treated using percutaneous catheter drainage guided by computed tomography. (From Webb WR et al: *Fundamentals of body CT,* ed 4, Philadelphia, 2015, Saunders.)

REFERRAL

- Interventional radiology
- General surgery
- Infectious diseases

PEARLS & CONSIDERATIONS

COMMENTS

Success of percutaneous drainage procedures is greater than 85%, and recurrence rates are about 1% to 10%.

BASIC INFORMATION

DEFINITION

The recurrent use of alcohol and/or drugs that causes clinically and functionally significant impairment, such as health problems, disability, and failure to meet major responsibilities at work, school, or home. The recent opiate crisis has resulted in high morbidity and mortality rates, highlighting its importance as a public health problem. The issue has been magnified by recent abuse of the highly potent synthetic opioid fentanyl and other agents.

SYNONYMS

Drug use
Addiction
Substance abuse

ICD-10CM CODE
F10-F19 Defined by specific substance
DSM-5
Depends on specific substance of abuse

EPIDEMIOLOGY & DEMOGRAPHICS

Genetic factors have a major influence on progression of substance use to dependence, whereas environmental factors unique to the individual play an important role in exposure and initial use of substances.

INCIDENCE: Peak period of both alcohol and illicit drug use disorders occurs in late adolescence and early adulthood, with a substantial reduction in substance use disorders after age 26 yr.

PREVALENCE: The lifetime prevalence of alcohol use disorders is approximately 8%, and prevalence of illicit drug use disorders is 2% to 3%.

PREDOMINANT SEX AND AGE: Substance abuse in general is more common among males than among females (1.3 times more).

GENETICS: Multiple biological mechanisms are involved in tolerance, craving, anxiety, dysphoria, executive cognitive function, and reward. Genome's role in neuroadaptation to drugs and the ways in which genetic variations and environmental exposures cause vulnerability to addictions are still under investigation. Addictive drugs induce adaptive changes in gene expression in brain reward regions, causing tolerance and habit formation with craving and negative affect. A specific effect of the μ-opioid receptor polymorphism (*OPRM1*; Asn40Asp) Asp40 to predict favorable naltrexone treatment response in alcoholism was recently replicated.

RISK FACTORS: Offspring of substance abusers were at twofold increased risk for any substance use disorder and a threefold risk for alcohol and marijuana abuse or dependence compared with offspring of control parents. Individuals who develop substance use disorders in adolescence are more likely to have those symptoms persist into adulthood.

Common risk factors are:

- Family history of addiction
- Being male
- Having another mental health disorder
- Peer pressure
- Lack of family involvement
- Taking a highly addictive drug

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical and behavioral symptoms are helpful to determine drug use. Bloodshot or glazed eyes, dilated or constricted pupils (7 or 8 mm pupil size may suggest the influence of cocaine, crack, meth, hallucinogens, or other stimulant; 1 or 2 mm pupil size may indicate the influence of heroin, opiates, or other depressant), abrupt weight changes, bruises, infections, and track marks are common physical signs. Behavioral changes occur as individual becomes more dependent on the drug. Increased aggression or irritability, sudden changes in social network, dramatic changes in habits and/or priorities, involvement in criminal activity, and financial problems are commonly observed.

ETIOLOGY

Theories are categorized into three main subgroups: social, psychological, and biological. There has been an emphasis on the role of personality, age of starting drug abuse, and hereditary and genetic factors. Some studies identified family as the most important and crucial risk factor for drug abuse in youth (lack of a safe and warm environment at home, insecure attachment between children and the parents, role modeling of the parents, loss of a parent, and lack of supervision). Peer pressure is also a strong risk factor. Although there is no general agreement on the gateway effect of drugs such as cannabis, poverty, neighborhood, living in poor and polluted suburbs, and low level of leisure facilities have been identified as impacting factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Use a motivational interviewing (MI) style and evidence-based interventions; identify and treat co-occurring medical and psychiatric conditions. Open-ended questions, affirmation, reflective listening, and summary reflections (OARS) are basic MI techniques.

WORKUP

Screening and assessment tools are available. CAGE (Cutdown, Guilty, Annoyed, Eyeopener) and AUDIT (Alcohol Use Disorders Identification Test) are commonly used for alcohol use disorder, and DAST (Drug Abuse Screening Test) is for drugs. CIWA-Ar (revised Clinical Institute Withdrawal Assessment for Alcohol scale assessment) and COWS (Clinical Opiate Withdrawal Scale) are used to assess the severity of alcohol and opioid withdrawal symptoms consequently.

LABORATORY TESTS

Blood alcohol levels, breathalyzer test results, urine drug screens, and, less commonly, hair and saliva analysis can be used to assess patients for possible alcohol and other drug use. Chemicals and their metabolites can be detected in the samples for limited times. Therefore, tests should be chosen and timed carefully.

IMAGING STUDIES

Imaging techniques such as positron emission tomography (PET), functional magnetic resonance imaging (fMRI), and electroencephalography (EEG) have been used to investigate these behaviors in drug-addicted human populations. However, there is no current therapeutic use or monitoring the outcome.

TREATMENT

Multiple treatment options for substance use disorders exist that can help individuals reach treatment goals. No single treatment is right for everyone. Treatment options should be discussed with patients and families to help them decide which ones are best for the patients' conditions. The outcomes of self-change efforts and treatment experiences should be reviewed frequently.

NONPHARMACOLOGIC THERAPY

Talk therapy has been shown to teach skills to avoid relapse, to reduce harmful substance use, and to improve health and quality of life. Cognitive behavioral therapy for substance use disorders and 12-step facilitation and motivational enhancement therapy are commonly used techniques. Peer support by Alcoholics Anonymous, Narcotics Anonymous, and SMART Recovery are also helpful.

ACUTE GENERAL Rx

Inpatient medically supervised withdrawal may be necessary for patients with symptoms of at least moderate alcohol withdrawal and patients with histories of severe withdrawal seizures. CIWA-Ar is a symptom-triggered approach to treatment of alcohol withdrawal with benzodiazepines. Diazepam (Valium), lorazepam (Ativan), and chlordiazepoxide (Librium) are the most frequently used benzodiazepines, with treatment often commencing when CIWA-Ar scores reach 8 to 10, with standing or as-needed dosing for scores from 11 to 20. Benzodiazepine use disorder also requires inpatient admission; tapering the drug in outpatient settings should be closely monitored. Comfort medications (clonidine, dicyclomine, loperamide, ibuprofen) are useful in management of opioid withdrawal symptoms. Buprenorphine, which requires a special DEA X license to prescribe, can be used for both withdrawal and long-term maintenance treatment. The *combo* product (Suboxone) contains buprenorphine, a partial mu opiate receptor agonist, and naloxone, a mu receptor antagonist, which is included to prevent dissolving of the buprenorphine for injectable use. Naloxone is not absorbed significantly when sublingually dissolved, while buprenorphine is. However, naloxone is potent when injected, causing acute withdrawal and thus serving as a

deterrent to buprenorphine abuse. Before starting buprenorphine, patients must be tapered off their opiates to avoid the acute withdrawal that comes with use of buprenorphine, which is strongly bound to the mu receptor. When buprenorphine is used for medically supervised opiate withdrawal, patients are required to go through mild to moderate withdrawal (COWS of >12) before the first dose of buprenorphine is given. Antipsychotics (i.e., haloperidol) may be considered for agitation, hallucinations, and other behavioral disturbances.

CHRONIC Rx

Acamprosate, disulfiram, naltrexone (oral or injectable), and topiramate are the medications that are commonly used for alcoholism treatment. Benzodiazepines should be avoided due to their own risk of addiction, and risk of triggering alcohol relapses. Because these are chronic conditions, the length of the treatment will depend on the individual treatment plan and the patient's success in achieving goals. Maintenance programs with methadone and buprenorphine may be continued for years.

COMPLEMENTARY & ALTERNATIVE MEDICINE

The top three therapies—religious/spiritual healing, relaxation techniques, and meditation—are commonly used adjunctive approaches. Neurofeedback and acupuncture are also reported as supportive.

DISPOSITION

Because of the nature of this chronic/relapsing condition, individuals should be referred to and monitored at outpatient drug and/or alcohol treatment centers. Other health conditions and co-occurring psychiatric disorder treatment can be provided at general mental health clinics. Drug rehabilitation may require a controlled environment, such as those in sober houses and long-term recovery clinics. Alcoholics Anonymous (AA) programs are also effective in providing peer support.

REFERRAL

https://findtreatment.samhsa.gov/

PEARLS & CONSIDERATIONS

COMMENTS

Goals of substance use disorder treatment:

- Stop the harmful use of addictive substances.
- Improve health and wellness.
- Live a self-directed life.
- Strive to reach full potential.
- Improve quality of life.

PREVENTION

Efforts typically focus on children and teens. Besides national recognition of substance use prevention, family-based, school-based, and community prevention programs focus on changing community conditions or policies so that the availability of substances is reduced.

PATIENT & FAMILY EDUCATION

Individuals are provided information to understand the many aspects of what substance abuse is; warning signs of addiction; information about how alcohol and specific drugs affect the mind and body; and the consequences of addiction. Family therapy and education play important roles in the change process. It remains to be seen how legalization of cannabis will affect the rate of early-onset psychotic illness, since cannabis is a known risk factor.

BASIC INFORMATION

DEFINITION

The Centers for Disease Control and Prevention (CDC) defines suicide and suicidal behavior as:

- Suicide.
- Death caused by self-directed injurious behavior with intent to die as a result of the behavior.
- Suicide attempt:
  1. A nonfatal self-directed potentially injurious behavior with intent to die as a result of the behavior. A suicide attempt may or may not result in injury.
     a. An estimated 1.3 million adults aged 18 or older (0.6) attempted suicide in the past yr.
     b. There is one suicide for every 25 attempted suicides.
- Suicidal ideation.
- Thinking about, considering, or planning for suicide:
  1. Among adults aged ≥18 yr in the U.S. during 2013.
     a. An estimated 9.3 million adults (3.9% of the adult U.S. population) reported having suicidal thoughts in the past yr (CDC 2015).
     b. An estimated 2.7 million adults (1.1% of the adult U.S. population) made a plan about how they would attempt suicide in the past yr (CDC 2015).
     c. Percentage of adults having serious thoughts about suicide was highest among adults aged 18 to 25 (7.4%), followed by adults aged 26 to 49 (4%) and then by adults aged 50 or older (2.7%).

SYNONYM

Self-murder

ICD-10CM CODES

X64	Intentional self-poisoning by an exposure to other and unspecified drugs, medicaments, and biological substances
X70	Intentional self-harm by hanging, strangulation and suffocation
X71	Intentional self-harm by drowning and submersion
X72	Intentional self-harm by handgun discharge
X75	Intentional self-harm by explosive material
X76	Intentional self-harm by smoke, fire and flames
X78	Intentional self-harm by sharp object
X81	Intentional self-harm by jumping or lying before moving object
X83	Intentional self-harm by other specific means

DSM-5: Categorized by method

EPIDEMIOLOGY & DEMOGRAPHICS

- Suicide was the tenth-leading cause of death for all ages in 2013. There were 41,149 suicides in 2013 in the U.S.—a rate of 12.6 per 100,000, which is equal to 113 suicides each day or 1 every 13 min (CDC 2015).
- CDC researchers wrote in a 2018 report that suicide rates in the U.S. have risen nearly 30% since 1999, and mental health conditions are one of several factors contributing to suicide. In addition, from 1999 to 2015, suicide rates increased among both sexes, all racial/ethnic groups, and all urbanization levels.
- During 2000 to 2016, the suicide rate among U.S. persons ages 16 to 64 yr increased 34%, from 12.9 per 100,000 population to 17.3.

DATA AND STATISTICS: Firearm suicides (CDC 2014):

- Number of deaths: 17,352
- Deaths per 100,000 population: 5.8

Suffocation suicides:

- Number of deaths: 8161
- Deaths per 100,000 population: 2.7

Poisoning suicides:

- Number of deaths: 6358
- Deaths per 100,000 population: 2.1

Suicidal deaths are only part of the problem. More people survive suicide attempts than actually die. They are often seriously injured and need medical and rehabilitative care.

AGE-RELATED DATA:

- Suicide is the third-leading cause of death among persons aged 10 to 14 yr, the second-leading among persons aged 15 to 34, the fourth-leading among persons aged 45 to 54, the eighth-leading among persons aged 55 to 64, and the seventeenth-leading among persons 65 yr and older.
- During 2002 to 2006, the greatest percentage of suicides occurred by firearm among all race/ethnicity groups for persons ages 65 yr and older. Except for Asian/Pacific Islanders, suffocation accounted for the highest percentage of suicides among those 65 yr and older (52.6%).

GENDER DIFFERENCES:

- Women attempt suicide about two to three times as often as men.
- Males succeed at taking their own lives at nearly four times the rate of females and represent 77.9% of all U.S. suicides.
- Suicide is the seventh-leading cause of death for males and the fourteenth-leading cause for females.
- Firearms are the most common method of suicide among males (56.9%).
- Poisoning is the most common method in women (34.8%).

ENVIRONMENTAL FACTORS:

- Suicide rates traditionally decrease in times of war and increase in times of economic crises.
- After adjusting for age, suicide rates are highest in the western and northwestern regions of the U.S.

MARITAL STATUS: Suicide rates are highest among the divorced, separated, and widowed and lowest among the married.

SUBSTANCE USE: CDC data from 16 National Violent Death Reporting System states in 2010: 33.4% of suicide decedents tested positive for alcohol, 23.8% for antidepressants, and 20% for opiates including heroin and prescription painkillers.

FINANCIAL IMPACT OF SUICIDES:

- Suicide results in an estimated $51 billion in combined medical and work lost costs to society (CDC 2015).
- The average suicide costs $1,164,499 (the estimate is based on 2010 CDC data and refers to people aged 10 and above).

SURVIVORS (CDC):

- A survivor of suicide is a family member or friend of a person who died by suicide.
- Surviving the loss of loved one to suicide is a risk factor for suicide.
- Surviving family members and close friends are deeply impacted by each suicide and experience a range of complex grief reactions including guilt, anger, abandonment, denial, helplessness, and shock.
- No exact figure exists, but it is estimated that a median of between 6 and 32 survivors exist for each suicide, depending on the definition used.
- According to another estimate, approximately 7% of the U.S. population knew someone who died of suicide during the past 12 months.

RISK FACTORS (CDC) (TABLE E1):

- Family history of suicide
- Family history of child maltreatment
- Previous suicide attempt(s)
- History of mental disorders, particularly clinical depression
- History of alcohol and substance abuse
- Feelings of hopelessness
- Impulsive or aggressive tendencies
- Cultural and religious beliefs (e.g., belief that suicide is noble resolution of a personal dilemma)
- Local epidemics of suicide
- Isolation, a feeling of being cut off from other people
- Barriers to accessing mental health treatment
- Loss (relational, social, work, or financial)
- Physical illness
- Easy access to lethal methods
- Unwillingness to seek help because of the stigma attached to mental health and substance abuse disorders or to suicidal thoughts
- Rates are higher in developing countries.
- Rates vary by occupation, ethnicity, and employment status.

PROTECTIVE FACTORS (CDC):

- Effective clinical care for mental, physical, and substance abuse disorders
- Easy access to a variety of clinical interventions and support for help seeking
- Family and community support (connectedness)
- Support from ongoing medical and mental health care relationships
- Skills in problem solving, conflict resolution, and nonviolent ways of handling disputes
- Cultural and religious beliefs that discourage suicide and support instincts for self-preservation

SUICIDAL BEHAVIOR:

- All suicidal behavior should be taken seriously, as a failed attempt may lead to a completed suicide in the future.
- Nearly half of suicides are preceded by an attempt that does not end in death.

TABLE E1 Suicide and Risk Factors: A Summary

Primary Diagnosis	Demographics	Personality Factors	Comorbidities	Social Factors	Other Factors
Bipolar	Male	Borderline	Substance abuse	Divorced	Means available
Schizophrenia	Older age	Narcissistic	Panic disorder	Widower	History of child abuse
Major depressive disorder	White race	Antisocial	Anxiety	Lives alone	Few reasons to live
Dysthymia	Homosexuality	Conduct disorder	Axis III dx	Isolated	Many adverse events
Adjustment disorder	History of attempt	Impulsive		Money worries	Change in grades
Conduct disorder	Family history			Other losses	Change in friends
Psychosis	Suicidal ideas			No religion	Giving things away
	Hopeless				Guns in the home
	Helpless				

dx, Diagnosis.
From Sadock BJ et al: *Kaplan & Sadock's comprehensive textbook of psychiatry,* ed 9, Philadelphia, 2009, Wolters Kluwer Health/Lippincott Williams & Wilkins.

- Those with a history of attempts are 23 times more likely to eventually end their own lives than those without.
- A suicidal gesture does not have death as a goal, but can serve as a dramatic way of alerting others to some type of ongoing distress.
- Risky behaviors such as speeding or disregarding traffic laws, or abusing drugs, are considered parasuicide when the person shows total disregard for whether the actions might result in his or her death.
- Unsuccessful suicide attempts may also result from miscalculations in the plan. These people are at high risk for attempting suicide again.

EVALUATION:

- Directly inquire into the presence of suicidal ideation. Approximately one half to two thirds of individuals who commit suicide visit physicians within 1 mo of taking their lives. Key components of the suicide evaluation are summarized in Table E2.
- Emergency evaluation: See https://www.nimh.nih.gov/research/research-conducted-at-nimh/asq-toolkit-materials/emergencydepartment/pdfs/bssa_155388.pdf
- Explicit suicidal intent, hopelessness, and a well-formulated plan indicate high risk. Clinicians can use the mnemonic SAL: Is the method specific? Is it available? Is it lethal? Remember to inquire about gun availability.
- The concurrence of multiple psychiatric problems, substance abuse, and multiple physical problems increases the risk.
- Covert suicidal ideation occurs in patients primarily with multiple vague physical complaints, depression, anxiety, or substance abuse.
- Primary care-feasible screening tools might help to identify some adults at increased risk for suicide but have limited ability to detect suicide risk in adolescents. Psychotherapy may reduce suicide attempts in some high-risk adults, but effective interventions for high-risk adolescents are not yet proven.

TABLE E2 Components of the Suicide Evaluation

- Conduct a thorough psychiatric examination.
  1. Establish initial rapport.
  2. Combine open-ended and direct questions.
  3. Gather information from family, friends, and coworkers.
  4. Conduct a mental status examination.
- Complete a suicide assessment.
  1. Ask specifically about thoughts of suicide and plans to commit suicide.
  2. Examine the details of the suicide plan.
  3. Determine the risk/rescue ratio.
  4. Assess the level of planning and preparation.
  5. Evaluate the degree of hopelessness.
  6. Identify precipitants.
- Establish a psychiatric and/or medical diagnosis.
  1. Obtain history.
  2. Use data from a psychiatric examination.
  3. Incorporate data from prior or current treaters.
- Estimate suicide risk.
  1. Evaluate risk factors.
  2. Evaluate available social supports.

From Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

ACUTE INTERVENTIONS:

- Place patient in a safe environment (usually hospitalization in a psychiatric unit or a medical unit with continuous observation).
- Emergency medical stabilization and clearance as required, related to severity and lethality of attempt, age, comorbid medical issues, and overall clinical presentation.

ACUTE PSYCHOPHARMACOLOGIC INTERVENTIONS:

- Benzodiazepines may be useful in reducing extreme anxiety and dysphoria in an acutely suicidal patient; however, these agents should not be prescribed until the means of the suicidal attempt are known (not a benzodiazepine overdose) and patient is medically stable (i.e., respiratory system, vital signs, cognitive functioning are stable).
- Antipsychotics (typicals or atypicals) can be used if psychosis is present (e.g., voices telling patient to hurt self) and to manage acute agitation.
- If indicated, mood stabilizers and antidepressants can be started in the acute setting but may have up to a 2-wk latency period. However, awareness of increased risk of suicidal thoughts/behavior with these medications in some populations is required.

THERAPY:

- Long-term: Psychotherapy aimed at factors that underlie the decision to pursue suicide or at the risk factors contributing to suicidal behavior. Remember that the basic suffering reflected in suicidality with its hopelessness and despair is often fueled by disconnectedness and loss of attachments.
- Substance abuse treatment (e.g., Alcoholics Anonymous, Narcotics Anonymous) when substance use disorder is present.
- Therapy should be aimed at the underlying condition (e.g., antidepressants for depression, anxiolytics or antidepressants for anxiety, substance abuse treatment, or psychotherapy for chronic low self-esteem, hopelessness).
- In elderly, loneliness and medical disability are major reasons for suicide and therefore major targets for intervention.
- Involvement of family members, spouse, loved one, caregivers if possible for therapy and management.
- A history of adverse childhood experiences increases suicide risk.

Superior Vena Cava Syndrome ALG

BASIC INFORMATION

DEFINITION

Superior vena cava (SVC) syndrome is a set of symptoms that results when a mediastinal mass compresses the SVC or the veins that drain into it, resulting in obstruction of blood flow from the head, neck, upper torso, or extremities to the right atrium.

SYNONYM

SVC

ICD-10CM CODES

I87.1	Compression of vein
S25.20XA	Unspecified injury of superior vena cava, initial encounter
S25.29XA	Other specified injury of superior vena cava, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

- SVC syndrome occurs in 15,000 persons in the U.S. every yr.
- More than 50% of patients present with SVC on presentation of malignancy.
- Mirrors lung cancer (especially small cell carcinoma) and lymphoma.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The pathophysiology of the syndrome involves increased pressure in the venous system draining into the SVC producing edema of the head, neck, and upper extremities. Symptoms develop over a period of 2 weeks in one third of patients and include:

- Shortness of breath
- Chest pain
- Cough
- Dysphagia, hoarseness, stridor
- Headache
- Syncope
- Visual trouble

Signs:

- Chest wall vein distention (Fig. E1)
- Neck vein distention
- Facial edema, facial plethora
- Upper-extremity swelling
- Cyanosis

ETIOLOGY

- Lung cancer (65% of all cases, of which half are small cell lung cancer)
- Lymphoma (15%)
- Thymoma
- Tuberculosis
- Goiter
- Aortic aneurysm (arteriosclerotic or syphilitic)
- SVC thrombosis:
  1. Primary: Associated with a central venous catheter
  2. Secondary: Complication of SVC syndrome associated with one of the above-mentioned causes
- Inflammatory process, fibrosing mediastinitis
- Fig. E2 illustrates the anatomy of superior vena cava syndrome. Table 1 summarizes common malignancies associated with SVC syndrome in adults.

DIAGNOSIS

Diagnostic imaging (Fig. E3 and E4): CT scan of the chest with contrast is the most useful diagnostic study. MRI is usually adequate to establish the diagnosis of SVC obstruction and to assist in the differential diagnosis of probable cause.

DIFFERENTIAL DIAGNOSIS

The syndrome is characteristic enough to exclude other diagnoses. The differential diagnosis concerns the underlying etiologies listed previously.

WORKUP

- Chest radiograph (mediastinal widening, pleural effusion)
- Chest CT with contrast or MRI (in patient who cannot tolerate contrast medium) usually confirms the diagnosis
- Venography: Rarely needed. Warranted only when an intervention (e.g., stent or surgery) is planned
- Percutaneous needle biopsy, endobronchial ultrasound-guided needle biopsy, or

TABLE 1 Malignancies Associated with Superior Vena Cava (SVC) Syndrome in Adults*

Neoplastic Diagnosis	Percentage of SVC	Percentage of Disease-Associated SVC
Lung cancer, stage 3B or 4:	48-81	
Small cell lung cancer		15-45
Squamous cell cancer		20-25
Adenocarcinoma		5-25
Large cell carcinoma		4-30
Lymphoma:	2-21	
Diffuse large cell lymphoma		64
Lymphoblastic lymphoma		33
Breast cancer	11	

*Includes lung cancer, lymphomas, and metastases from other solid tumors. 75% to 85% of patients with SVC have neoplastic disease.
From Zipes DP et al (eds): *Braunwald's heart disease,* ed 7, Philadelphia, 2005, Saunders.

BOX 1 Approach to Patients with Superior Vena Cava Obstruction

The diagnosis is established by physical examination and clinical presentation (see text).

- Respiratory status should be assessed promptly. Only patients in extremis should be treated urgently with radiation therapy or stent placement without a histologic diagnosis. Emergency therapy is necessary in fewer than 5% of all superior vena cava (SVC) obstruction cases.
- Diagnostic evaluation should proceed with the least invasive procedures performed initially followed by more invasive procedures as needed to obtain histologic diagnosis:
  1. Chest radiography
  2. Sputum cytology
  3. Thoracentesis with cytologic evaluation of fluid
  4. Node biopsy if a palpable node is present; avoid fine-needle aspiration if lymphoma is suspected
  5. Fiber-optic bronchoscopy with endobronchial ultrasound
  6. Mediastinoscopy with video-assisted imaging
  7. Thoracostomy with video-assisted imaging
- Evaluation may vary depending on the age and sex of the patient:
  1. In older adults (i.e., ≥50 years), the most common cause of SVC obstruction is lung cancer; lymphoma and metastatic cancer are less common, and benign processes are uncommon.
  2. In young adults (<50 years old), the most common cause of SVC obstruction is lymphoma (usually large cell lymphoma or lymphoblastic lymphoma; rarely Hodgkin disease). Lung cancer and thoracic malignancy are less common. Germ cell cancer (almost never in female patients) and benign causes are uncommon. The preceding evaluation should be modified to include the following studies before more invasive procedures are performed:
     a. Serum tumor markers (i.e., β-human chorionic gonadotropin, α-fetoprotein, and lactate dehydrogenase)
     b. Bone marrow aspiration and biopsy

From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 2 Comparison of Treatment Modalities for Malignancy-Related Superior Vena Cava Obstruction

Modality	Time to Symptom Relief	Percentage with Symptom Response	Potential for Combined Modality Therapy
Radiation therapy	3-30 days	56-96	Yes
Chemotherapy	1-2 weeks	59-77	Yes
Stent placement	0-72 hours	78-95	Yes

From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

mediastinoscopy are usually the initial diagnostic modalities used to establish a histologic diagnosis
- Box 1 summarizes an approach to patients with superior vena cava obstruction.

Rx TREATMENT

- Tissue diagnosis is usually needed before commencing therapy. EBUS is now considered the first step in evaluation. Mediastinoscopy would be considered if EBUS is non-diagnostic or there is high clinical suspicion for lymphoma.
- Management is guided by the severity of the symptoms and the underlying etiology. Table 2 compares treatment modalities for malignancy-related superior vena cava obstruction.
- Most patients with SVC do not require emergency intervention. Emergency empiric radiation is indicated in critical situations such as respiratory failure or central nervous system signs associated with increased intracranial pressure.
- Treatment of the underlying malignancy:
  1. Radiotherapy: The majority of tumors causing SVC syndrome are sensitive to radiotherapy
  2. Systemic chemotherapy
- Anticoagulant or fibrinolytic therapy in patients who do not respond to cancer treatment within a week or if an obstructing thrombus has been documented.
- Loop diuretics are often used, but their effect is limited.
- Upright positioning and fluid restriction until collateral channels develop and allow for clinical regression are useful modalities for SVC syndrome secondary to benign disease.
- Steroids (dexamethasone 4 mg q6h) may be useful in reducing the tumor burden in lymphoma and thymoma after definitive diagnosis is made.
- Percutaneous self-expandable stents that can be placed under local anesthesia with radiologic manipulation are useful in the treatment of SVC syndrome to bypass the obstruction, especially in cases associated with malignant tumors.
- Surgical bypass grafting is infrequently used to treat SVC syndrome.
- Fig. 5 illustrates a management algorithm for superior vena cava obstruction.

REFERRAL

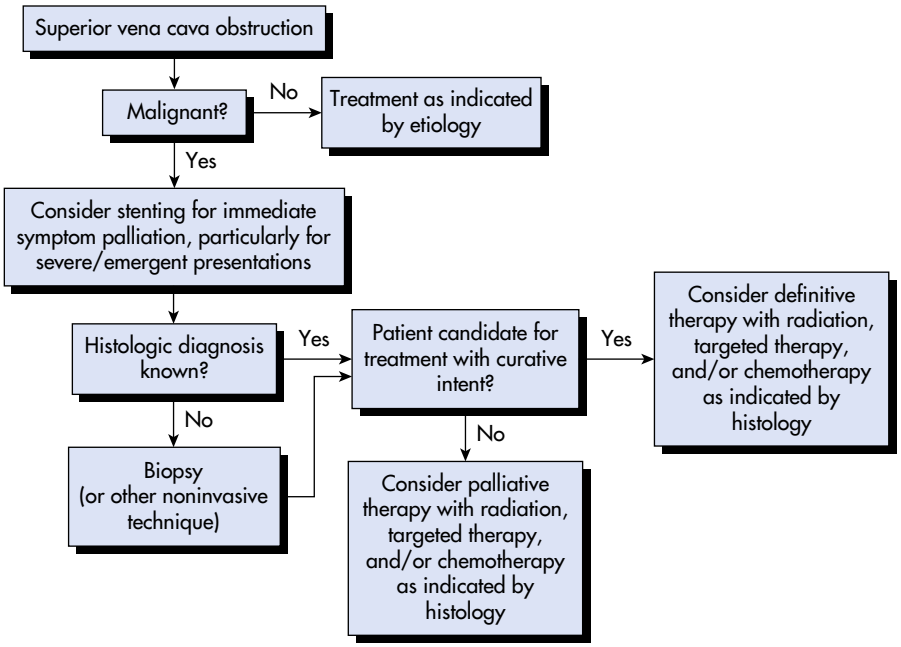

FIG. 5 A management algorithm for superior vena cava obstruction. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

FIG. E1 A patient with characteristic venous dilation and facial edema. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

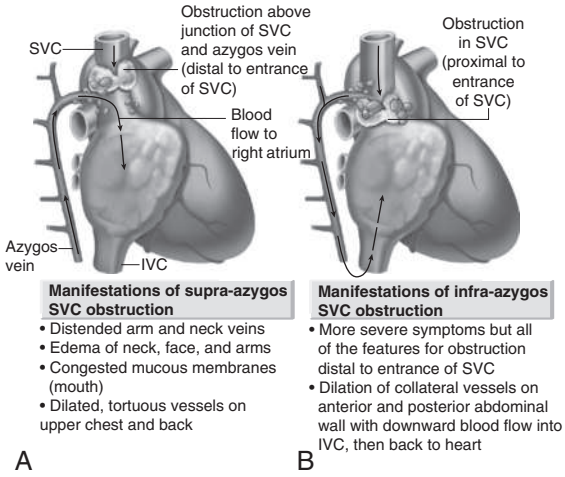

FIG. E2 Superior vena cava (SVC) syndrome secondary to external compression of the SVC by a lung tumor and thrombosis of the SVC. A, Initial venogram showing compression of the superior vena cava and filling defects because of thrombus. **B,** Venogram after 24 hours of catheter-directed thrombolysis with resolution of the thrombus but residual stenosis. **C,** Balloon venoplasty. **D,** Final angiogram after deployment of a self-expanding stent. *RA,* Right atrium. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.)

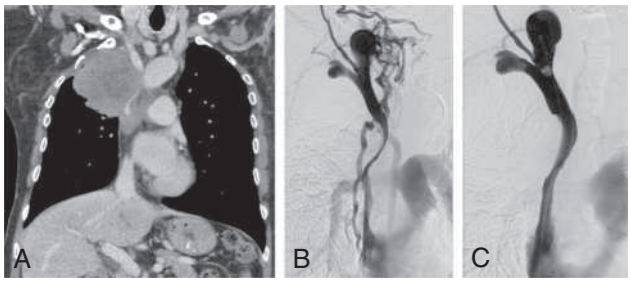

FIG. E3 A 58-year-old man presented with facial edema, bilateral upper extremity swelling and shortness of breath. A coronal reconstruction image **(A)** from a contrast-enhanced computed tomography scan shows a large right upper lobe mass extending into the mediastinum with severe compression of the superior vena cava. Venography **(B)** confirms severe stenosis of the superior vena cava with multiple mediastinal collaterals. The obstruction is inferior to the azygos vein confluence with the superior vena cava. The patient was treated with placement of an intravascular stent (Wall Stent, Boston Scientific, Natick, MA). Post-stent venography **(C)** shows a widely patent superior vena cava and disappearance of collaterals in the thorax. The symptoms improved within 12 hours. Subsequently, a biopsy was performed, which confirmed small cell lung cancer. The patient received radiation therapy. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

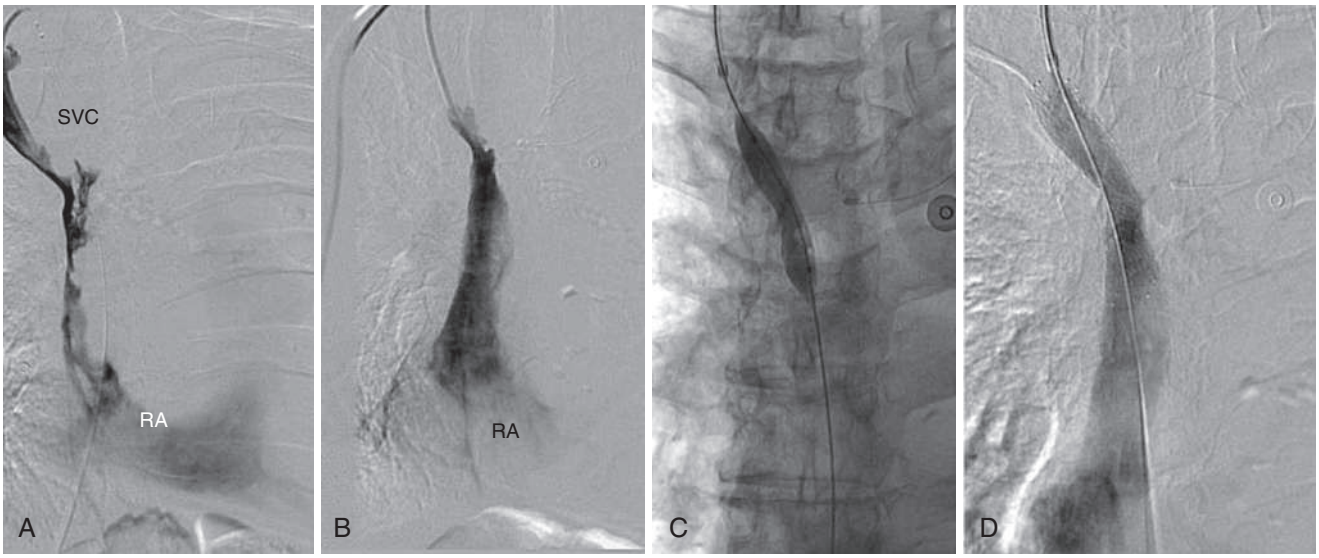

FIG. E4 Anatomy of superior vena cava (SVC) syndrome. Lymph nodes may obstruct blood return above the entrance of the azygos vein **(A),** resulting in edema of the face, neck, and arms and distended veins in the neck and arms and over the upper chest. Obstruction below the return of the azygos vein **(B)** results in retrograde flow through the azygos through collateral veins to the inferior vena cava (IVC), with all the symptoms and signs in **A** plus dilation of the veins over the abdomen as well. (Modified from Skatin AT [ed]: *Atlas of diagnostic oncology,* ed 3, Philadelphia, 2003, Elsevier.)

BASIC INFORMATION

DEFINITION

Supraventricular tachycardia (SVT) is a group of rapid regular tachyarrhythmia. There are three major categories of SVT:

1. Atrial tachycardia (AT): An arrhythmia that originates from the atrium and does not involve the AV node. This is usually a focal arrhythmia. In some cases, the underlying mechanism may be a reentry circuit, either a small circuit (microreentry) or a large circuit (macroreentry)
2. AV nodal reentrant tachycardia (AVNRT)
3. AV reentrant tachycardia (AVRT) (Fig. 1)

The latter two are reentrant arrhythmia that always involve the AV node as part of the circuit (Fig. 1).

Other forms of arrhythmia that involve the atria, such as atrial fibrillation and atrial flutter, have distinct electrocardiographic features and are covered in separate chapters. Rare forms of SVT such as inappropriate sinus tachycardia, sinus mode reentry tachycardia, and junctional tachycardia are beyond the scope of this chapter.

SYNONYMS

SVT
Paroxysmal supraventricular tachycardia
PSVT

ICD-10CM CODE
I47.1 Supraventricular tachycardia

EPIDEMIOLOGY & DEMOGRAPHICS

SVT is most commonly diagnosed between the ages of 12 and 30. SVT occurs most commonly in patients with no prior cardiac conditions. AVNRT is the most common type of SVT in both genders and in all ages. It occurs most commonly in young women. AVRT is the second most common SVT, and it is typically diagnosed in younger patients as compared to the age of patients with AVNRT. AT is more commonly associated with structural heart disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients may be either symptomatic or asymptomatic.
- Patient may be aware of "fast" regular heartbeat (but sometimes complain of irregular heartbeat: palpitations); may complain of weakness, dyspnea, dizziness, chest pain, presyncope or, rarely, syncope.
- Patients with AVNRT may complain of neck pounding during the episode due to simultaneous contraction of the atria and ventricles with closed AV valves causing a sharp increase in atrial and jugular venous pressure.
- In some cases the episodes can be triggered by physical activity or psychological stress, but in others there may not be an obvious trigger. In patients with AVNRT, sometimes the arrhythmia is reproducibly initiated when bending forward to pick up an item from the floor.
- Hemodynamic status during the arrhythmia may vary and depend on the patient's comorbidities and presence of underlying structural heart disease. Usually, patients are hemodynamically stable.
- Physical examination is most commonly normal and unrevealing, except rapid regular heart rate and occasionally hypotension. In patients with AVNRT sharp tall jugular vein A waves may be seen when the right atrium contracts against a closed tricuspid valve.

ETIOLOGY (SEE FIG. 1)

- AVNRT: Dual electrical pathways within the AV node. In typical AVNRT the anterograde limb conducts slowly (slow pathway) and the retrograde limb has fast conduction properties (fast pathway), and vice versa in atypical AVNRT.
- AVRT is accessory pathway mediated, either orthodromic (antegrade through the AV node and retrograde through the accessory pathway) or, much less commonly, antidromic (antegrade through the accessory pathway and retrograde through the AV node). In the case of antidromic tachycardia, the QRS will be wide and fully preexcited. In some patients, the presence of accessory pathway is not evident on the baseline ECG (concealed accessory pathway), while in others it is manifest in the baseline ECG, presenting the typical features of the Wolff-Parkinson-White (WPW) syndrome.
- Paroxysmal atrial tachycardia and multifocal atrial tachycardia: abnormal automaticity of atrial tissue or triggered activity. In some cases (especially in patients who underwent previous cardiac surgery such as valve replacement or ASD closure), the underlying mechanism is macroreentrant AT.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

The diagnosis of SVT relies principally on the 12-lead ECG. Every patient suspected of having an episode of SVT should have a 12-lead ECG done immediately. Typically, patients with SVT will present with a narrow complex QRS tachycardia with a ventricular rate faster than 100 beats per minute (bpm) and typically faster than 130 to 150 bpm.

P wave morphology can be useful in discriminating rhythms. P waves with a similar axis to the sinus node can be atrial tachycardias and sinus tachycardias. P waves with retrograde depolarization of the atria (seen as inverted in the inferior leads) can be seen in AVNRT, AVRT, and atrial tachycardia. Sawtooth P waves are indicative of classical counterclockwise typical type I flutter, and an absence of P waves with irregular R-R intervals points to atrial fibrillation. Variable (>3) morphologies of P wave are suggestive of multifocal atrial tachycardia. Wide QRS complex (>0.12 sec) with initial slurring (delta wave) during sinus rhythm and short PR (<0.12 sec) is characteristic of Wolff-Parkinson-White syndrome.

In typical AVNRT, due to the small size of the circuit within the AV node and the fast retrograde conduction, there is simultaneous depolarization of the ventricles and atria, thus making the P wave "buried" in the QRS and

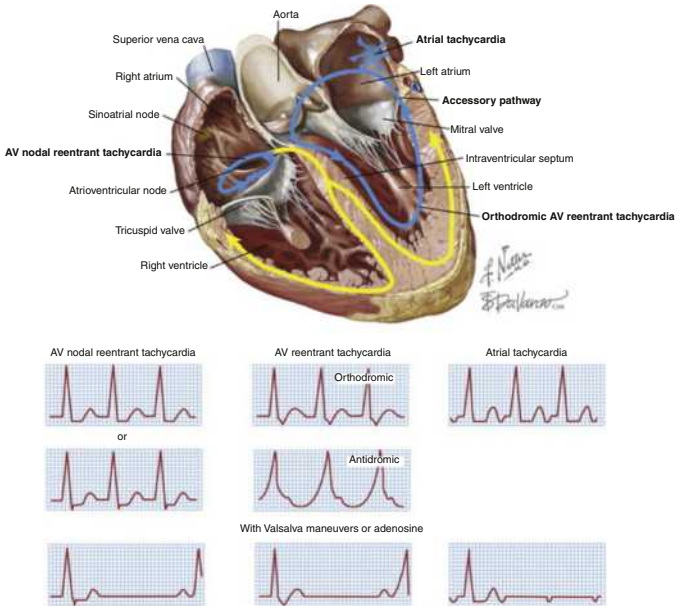

FIG. 1 Typical electrocardiographic recordings and anatomic representation of the common supraventricular tachycardias. *AV,* Atrioventricular. (From Runge MS et al [eds]: *Netter's cardiology,* ed 2, Philadelphia, 2010, Saunders. Adapted from Delacretaz E: Clinical practice: supraventricular tachycardia, *N Engl J Med* 354:1039-1051, 2006.)

therefore not visible or inscribed very close to the QRS at the final part of the QRS complex, and sometimes creating a "pseudo terminal S wave" usually seen in leads II, III, and aVF and "pseudo terminal R waves" at the end of the QRS in V1 and avR (Fig. 1).

In orthodromic AVRT, the P wave is usually visible close after the QRS due to the rapid conduction properties of the accessory pathway (short RP tachycardia). In AT, the P wave is usually noticed farther away after the QRS (long RP tachycardia) (Fig. 1).

Other diagnostic maneuvers that may assist in the differential diagnosis are vagal maneuvers (such as carotid sinus massage) or giving intravenous AV nodal blocking agents such as adenosine or verapamil) to produce AV nodal conduction block. This will terminate reentrant arrhythmia dependent on the AV node—AVNRT and AVRT—but not AT, which will continue, albeit with nonconducted P waves.

Other arrhythmias that present with narrow complex tachycardia like PSVT are:

- Fascicular VT
- Junctional tachycardias
- Artifact such as with Parkinson disease

SVT can conduct with bundle branch block (BBB) and wide QRS either due to preexisting BBB on the baseline ECG or due to aberrant conduction (rapid rate–dependent BBB). When a patient presents with wide QRS tachycardia, VT must be excluded first. Features to distinguish SVT from ventricular tachycardia are outlined in Table 1.

WORKUP

- Electrocardiography
- Echocardiography to exclude structural heart disease
- Thyroid function tests
- Complete blood count to exclude anemia or infection as an underlying trigger for the event
- In most cases the workup will be negative, with no underlying cardiac or systemic pathology and no clear triggers for an acute episode
- Holter or event monitor to document the arrhythmias if they are paroxysmal and not documented yet

TABLE 1 Features That May Differentiate Ventricular Tachycardia from Supraventricular Tachycardia with Aberrancy

Helpful Features	Implications
Positive QRS concordance	Diagnostic of VT
Presence of AV dissociation, capture beats, or fusion beats	Diagnostic of VT
Atypical RBBB (monophasic R, QR, RS, or triphasic QRS in V1; R:S ratio <1, QS or QR, monophasic R in V6)	Suggests VT
Atypical LBBB (R >30 min or R to S [nadir or notch] >60 min in V1 or V2; R:S ratio <1, QS or QR in V6)	Suggests VT
Shift of axis from baseline	Suggests VT
History of CAD	Suggests VT
QRS during tachycardia identical to QRS during sinus rhythm	Suggests SVT
Termination with adenosine	Suggests SVT

AV, Atrioventricular; *CAD,* coronary artery disease; *LBBB,* left bundle branch block; *RBBB,* right bundle branch block; *SVT,* supraventricular tachycardia; *VT,* ventricular tachycardia.

Stambler BS et al: Etripamil nasal spray for rapid conversion of supraventricular tachycardia to sinus rhythm, *J Am Coll Cardiol* 72:489-497, 2018.

Rx TREATMENT (FIG. 2)

NONPHARMACOLOGIC THERAPY

Acute termination: If the patient is hemodynamically unstable, prompt synchronized cardioversion with an external defibrillator using 50 to 100 J should be performed.

If the patient is stable, Valsalva maneuver in the supine position is the most effective way to terminate most types of SVT; carotid sinus massage (after excluding occlusive carotid disease and murmurs over the carotid arteries) is also commonly used to elicit vagal efferent impulses. These are effective in terminating AVRT, AVNRT, and may occasionally terminate some types of atrial tachycardia, but in the case of sinus tachycardia, atrial flutter, and atrial fibrillation, they only transiently slow down AV conduction without terminating the actual tachycardia.

PHARMACOLOGIC THERAPY

- Adenosine is useful to terminate acutely orthodromic AVRT and AVNRT and can uncover the underlying rhythm in paroxysmal atrial tachycardia (Fig. 3); it is the first choice of therapy for treatment of almost all episodes of SVT unresponsive to vagal maneuvers. The dose is 6 mg given as a rapid IV bolus; tachycardia is usually terminated within a few seconds. If this fails, one may repeat with 12

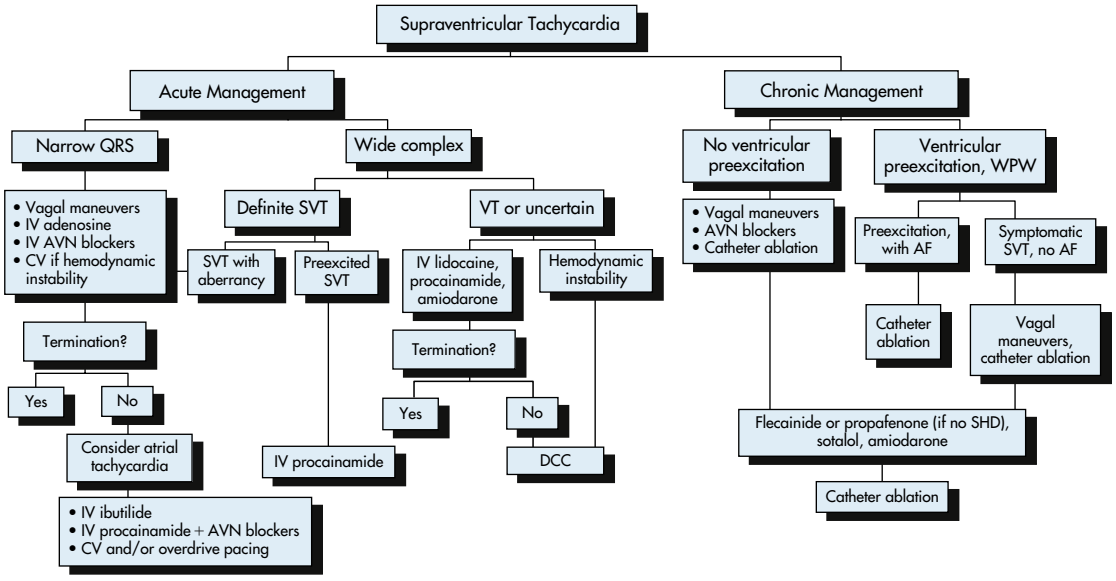

FIG. 2 Supraventricular tachycardia. *AF,* Atrial fibrillation; *AVN,* atrioventricular node; *CV,* cardioversion; *IV,* intravenous; *DCC,* direct current cardioversion; *SHD,* structural heart disease (no overt evidence of myocardial, valvular, congenital or coronary heart disease); *SVT,* supraventricular tachycardia; *VT,* ventricular tachycardia; *WPW,* Wolff-Parkinson-White. (From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

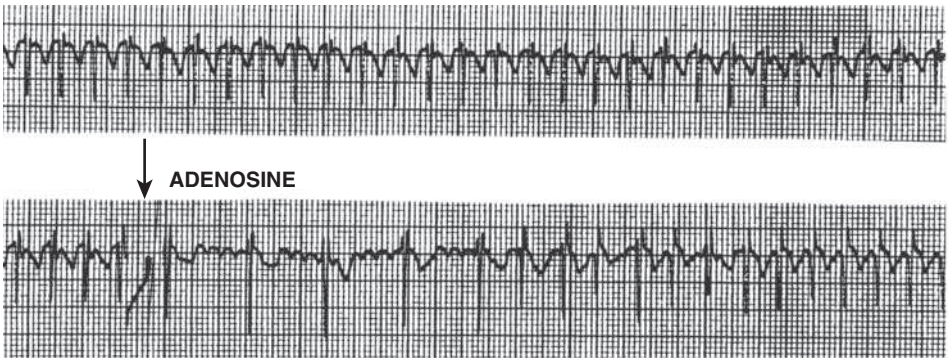

FIG. 3 Adenosine can uncover the mechanism of supraventricular tachycardia. A 3-month-old infant developed an extremely fast, narrow QRS complex tachycardia and a heart rate of 220 beats/min after insertion of a central line through a jugular vein. Adenosine produced a transient atrioventricular block and unmasked very rapid atrial fibrillation waves (570 beats/min). (From Park MK: *Park's Pediatric cardiology for practitioners,* ed 6, Philadelphia, Elsevier, 2014.)

mg IV bolus. Contraindications are second- or third-degree atrioventricular block; WPW with atrial fibrillation; sick sinus syndrome; and chronic use of drugs such as dipyridamole, theophylline, or aminophylline; and heart transplant. Adenosine may cause bronchospasm in asthmatics.

- Verapamil 5 to 10 mg IV is given over 5 min; if no effect, may repeat in 30 min.
  1. Verapamil should be used cautiously in patients with SVT associated with hypotension.
  2. Slow injection of calcium chloride (10 ml of a 10% solution given over 5 to 8 min before verapamil administration) decreases the hypotensive effect without compromising its antiarrhythmic effect.
- Metoprolol (IV 5 mg/2 min up to 15 mg) or esmolol (500 μg/kg IV bolus, then 50 μg/kg/min) may be effective in the treatment of SVT.
  - IV digoxin (0.75 to 1 mg slow IV loading in increments of 0.25 mg over several hours) is rarely used in SVT but may tried if other agents are not effective.
  - Digoxin, beta-blockers, and calcium-channel blockers should be avoided in patients with pre-excitation syndrome and antidromic AVRT or preexcited atrial fibrillation to avoid increased conduction through the accessory pathway.
  - Recently a new rapidly acting intranasal calcium-channel blocker—etripamil—was reported to be effective in rapid conversion of SVT to sinus rhythm. This may prove in the future to be an important treatment modality but is not yet available for routine clinical use.

CHRONIC TREATMENT

The goal is prevention of recurrent episodes. In patients with infrequent and minimally symptomatic episodes without preexcitation, it is optional to provide treatment only during acute episodes. In patients with recurrent symptomatic episodes, regular treatment with beta-blockers or nondihydropyridines calcium channel blockers can be tried; if these fail, class Ic antiarrhythmics are an option. It is also possible to treat patients who have infrequent symptomatic episodes with a "pill-in-the-pocket" strategy with either beta-blockers or other antiarrhythmics. Patients who fail antiarrhythmic therapy, develop side effects due to medications, or refuse medical therapy should be referred for catheter ablation. This is a highly effective mode of treatment with low risk of complications. Recent studies show that ablation therapy is highly effective, safe, and associated with a very low recurrence rate.

DISPOSITION

Most patients respond well with resolution of the SVT upon treatment (see "Acute General Rx"). Some patients may need chronic AV blocking agents for recurrence.

REFERRAL

Radiofrequency ablation (RFA) is the procedure of choice in symptomatic patients who are refractory to medical therapy especially in AVRT, AVNRT, and atrial flutter. RFA has high efficacy rates (single procedure success is 93.2%), low all-cause mortality (0.1%), and low adverse events (2.9%). Despite high reported success rates, RFA appears to be underused in clinical practice.

BASIC INFORMATION

DEFINITION

Syncope is the transient loss of consciousness with spontaneous recovery that results from an acute global reduction in cerebral blood flow. There are three major types: neurocardiogenic, orthostatic, and cardiac. Syncope is a symptom, and the goal is to distinguish lethal causes from benign causes of transient loss of consciousness.

ICD-10CM CODE
R55 Syncope and collapse

EPIDEMIOLOGY & DEMOGRAPHICS

- Syncope accounts for 3% to 5% of emergency department visits.
- 30% of the adult population will experience at least one syncopal episode during their lifetimes.
- Incidence of syncope is highest in elderly men and young women.
- 15% of children and adolescents experience syncope; fewer than 5% have cardiac causes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Blood pressure: If low, consider orthostatic hypotension; if unequal in both arms (difference >20 mm Hg), consider subclavian steal or dissecting aneurysm. (NOTE: Blood pressure [BP] and heart rate should be recorded in the supine and standing positions, waiting at least 5 minutes between each position.) If there is a drop in BP but no change in heart rate (HR), the patient may be taking a beta-blocker or may have an autonomic neuropathy.
- Pulse: If patient has tachycardia, bradycardia, or irregular rhythm, consider arrhythmia.
- Heart: If there are murmurs present, consider syncope attributable to left ventricular outflow obstruction (aortic stenosis or idiopathic hypertrophic subaortic stenosis); if there are jugular venous distention and distal heart sounds, consider cardiac tamponade.
- Carotid sinus pressure: Can be diagnostic if it reproduces symptoms and other causes are excluded; a pause >3 sec or a systolic BP drop >50 mm Hg without symptoms or <30 mm Hg with symptoms when sinus pressure is applied separately on each side for <5 sec is considered abnormal. This test should be avoided in patients with carotid bruits or cerebrovascular disease. ECG monitoring, IV access, and bedside atropine should be available when carotid sinus pressure is applied.

ETIOLOGY

- Neurocardiogenic or neurally mediated syncope: most common type, accounting for two-thirds of cases. It includes vasovagal, situational, carotid hypersensitivity, and postexertional syncope (Box 1).
  1. Psychophysiologic (emotional upset, panic disorders, hysteria, hyperventilation)
  2. Visceral reflex (micturition, defecation, food ingestion, coughing, ventricular contraction, glossopharyngeal neuralgia)
  3. Carotid sinus pressure
  4. Reduction of venous return caused by Valsalva maneuver
  5. Postural tachycardia syndrome (POTS)
- Orthostatic hypotension (10% of cases):
  1. Hypovolemia
  2. Vasodilator medications
  3. Autonomic neuropathy (diabetes, amyloid, Parkinson disease, multisystem atrophy)
  4. Pheochromocytoma
  5. Carcinoid syndrome
- Cardiac (10% to 20%):
  1. Reduced cardiac output:
     a. Left ventricular outflow obstruction (aortic stenosis, hypertrophic cardiomyopathy)
     b. Obstruction to pulmonary flow (pulmonary embolism, pulmonic stenosis, primary pulmonary hypertension)
     c. Myocardial infarct with pump failure
     d. Cardiac tamponade
     e. Mitral stenosis
     f. Reduction of venous return (atrial myxoma, valve thrombus)
     g. Beta-blocker therapy
  2. Arrhythmias or asystole:
     a. Extreme tachycardia (>160 to 180 beats/min)
     b. Severe bradycardia (<30 to 40 beats/min)
     c. Sick sinus syndrome
     d. Atrioventricular block (second or third degree)
     e. Ventricular tachycardia or fibrillation
     f. Long QT syndrome
     g. Pacemaker malfunction
     h. Psychotropic medications and beta-blockers (Table 1)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Seizure (see "Workup").
- Vertebrobasilar transient ischemic attack (TIA) usually manifests as diplopia, vertigo, or ataxia but not loss of consciousness. Isolated episodes of transient loss of consciousness (TLOC, Fig. E1) without accompanying neurologic symptoms are unlikely to be TIAs.

BOX 1 Causes of Syncope

Reflex Syncopal Syndromes
- Vasovagal faint (common faint)
- Carotid sinus syncope
- Situational faint:
  1. Acute hemorrhage
  2. Cough, sneeze
  3. Gastrointestinal stimulation (swallow, defecation, visceral pain)
  4. Micturition (postmicturition)
  5. Postexercise
  6. Pain, anxiety
- Glossopharyngeal and trigeminal neuralgia

Orthostatic
- Aging
- Antihypertensives
- Autonomic failure:
  1. Primary autonomic failure syndromes (e.g., pure autonomic failure, multiple system atrophy, Parkinson disease with autonomic failure)
  2. Secondary autonomic failure syndromes (e.g., diabetic neuropathy, amyloid neuropathy)
- Medications
- Volume depletion:
  1. Hemorrhage, diarrhea, Addison disease, diuretics, febrile illness, hot weather

Cardiac Arrhythmias
- Sinus node dysfunction (including bradycardia-tachycardia syndrome)
- Atrioventricular conduction system disease
- Paroxysmal supraventricular and ventricular tachycardias
- Implanted device (pacemaker, implantable cardioverter defibrillator) malfunction
- Drug-induced proarrhythmias

Structural Cardiac or Cardiopulmonary Disease
- Cardiac valvular disease:
  1. Acute myocardial infarction, ischemia
  2. Obstructive cardiomyopathy
  3. Atrial myxoma
  4. Acute aortic dissection
  5. Pericardial disease, tamponade
  6. Pulmonary embolus, pulmonary hypertension

Cerebrovascular
- Vascular steal syndromes

Multifactorial

Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

TABLE 1 Drugs That Can Cause or Contribute to Syncope

Drug	Mechanism
Diuretics	Volume depletion
Vasodilators: • Angiotensin-converting enzyme inhibitors • Calcium channel blockers • Hydralazine • Nitrates • α-Adrenergic blockers • Prazosin	Reduction in systemic vascular resistance and venodilation
Other antihypertensive drugs: • α-Methyldopa • Clonidine • Guanethidine • Hexamethonium • Labetalol • Mecamylamine • Phenoxybenzamine	Centrally acting antihypertensives
Drugs associated with torsades de pointes: • Amiodarone • Disopyramide • Encainide • Flecainide • Quinidine • Procainamide • Sotalol	Ventricular tachycardia associated with a prolonged QT interval
Digoxin	Cardiac arrhythmias
Psychoactive drugs: • Tricyclic antidepressants • Phenothiazines • Monamine oxidase inhibitors • Barbiturates	Central nervous system effects causing hypotension; cardiac arrhythmias
Alcohol	Central nervous system effects causing hypotension; cardiac arrhythmias

Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

- Recreational drugs or alcohol.
- Functional causes such as somatoform disorders.
- Sleep disorders, such as sleep attacks and narcolepsy, are also in the differential for TLOC.
- Head trauma.

WORKUP

The history is crucial to diagnosing the cause of syncope and may suggest a diagnosis that can be evaluated with directed testing. History is also important to determine other etiologies for TLOC, such as seizure.

- Sudden loss of consciousness (LOC): Consider cardiac arrhythmias.
- Gradual LOC: Consider orthostatic hypotension, vasodepressor syncope, hypoglycemia.
- History of aura before LOC or prolonged confusion (>1 min), amnesia, or lethargy after LOC suggests seizure rather than syncope.
- Patient's activity at the time of syncope:
  1. Micturition, coughing, defecation: Consider syncope caused by decreased venous return.
  2. Turning head or while shaving: Consider carotid sinus syndrome.
  3. Physical exertion in a patient with murmur: Consider aortic stenosis.
  4. Arm exercise: Consider subclavian steal syndrome.
  5. Assuming an upright position: Consider orthostatic hypotension.
- Associated events:
  1. Chest pain: Consider myocardial infarction, pulmonary embolism.
  2. Palpitations: Consider arrhythmias or POTS.
  3. Incontinence (urine or fecal) and tongue biting are associated with seizure or syncope.
  4. Brief, transient shaking after LOC may represent myoclonus from global cerebral hypoperfusion and not seizures. However, sustained tonic/clonic muscle action is more suggestive of seizure.
  5. Focal neurologic symptoms or signs point to a neurologic event such as a seizure with residual deficits (e.g., Todd paralysis) or cerebral ischemic injury.
  6. Psychologic stress: Syncope may be vasovagal.
  7. Multiple nonspecific symptoms (fatigue, diffuse weakness, headache, "brain fog," exercise intolerance, "coat hanger sign") can be seen in POTS and neurogenic orthostatic hypotension and may have psychophysiologic or functional causes.
- Review current medications, particularly antihypertensive and psychotropic drugs.
- Carotid sinus massage (CSM) may be reasonable in patients older than 40 with syncope of unknown origin and possibly due to vasovagal mechanism. It is contraindicated in patients with carotid disease.
- Table 2 differentiates syncope caused by neutrally mediated hypotension, arrhythmias, seizures, and psychogenic causes.
- Fig. 2 illustrates an approach to the evaluation of syncope.

LABORATORY TESTS

Routine blood tests rarely yield diagnostically useful information and should be done only if they are specifically suggested by the results of the history and physical examination. The following are commonly ordered tests:

- Pregnancy test in women of childbearing age
- Complete blood count to look for anemia and signs of infection
- Electrolytes, blood urea nitrogen, creatinine, magnesium, and calcium to look for electrolyte abnormalities and evaluate fluid status
- Serum glucose level
- Cardiac troponins, especially if the patient gives a history of chest pain before the syncopal episode
- Drug and alcohol levels with suspected toxicity

IMAGING STUDIES

- ECG to rule out arrhythmias; may be diagnostic in 5% to 10% of patients.
- Echocardiography. Indicated in patients where initial evaluation suggests structural heart disease (based on physical exam and/or ECG) or have known heart disease.
- If seizure is suspected, MRI of the brain and electroencephalogram may be useful.
- If head trauma or neurologic signs on examination, CT or MRI may be helpful.
- If arrhythmias are suspected, a 24-hr Holter monitor or admission to a telemetry unit in high risk patients is appropriate. In general, Holter monitoring is rarely useful, revealing a cause for syncope in <3% of cases. Loop recorders that can be activated after syncopal episode to retrieve information about the cardiac rhythm during the preceding 4 min add considerable diagnostic yield in patients with unexplained syncope.
- Implantable cardiac monitors that function as permanent loop recorders or implantable cardioverter-defibrillators, which are placed subcutaneously in the pectoral region with the patient under local anesthesia, are useful in patients with cardiac syncope.
- Electrophysiologic studies may be indicated in patients with structural heart disease and/or recurrent syncope.

TILT-TABLE TESTING

- Useful to support a diagnosis of neurocardiogenic syncope. Patients age >50 yr should have stress testing before tilt-table testing. Positive results would preclude tilt-table testing.
- Indicated in patients with recurrent episodes of unexplained syncope as well as patients in high-risk occupations (e.g., pilots, bus drivers). The test is also useful for identifying patients with prominent bradycardic

TABLE 2 Differentiation of Syncope Caused by Neurally Mediated Hypotension, Arrhythmias, Seizures, and Psychogenic Factors

	Neurally Mediated Hypotension	Arrhythmias	Seizures	Psychogenic
Demographics and clinical setting	Female > male sex Younger age (<55 yr) More episodes (>2) Standing, warm room, emotional upset	Male > female sex Older age (>54 yr) Fewer episodes (<3) During exertion or when supine Family history of sudden death	Younger age (<45 yr) Any setting	Female > male sex Occurs in presence of others Younger age (<40 yr) Many episodes (often many episodes in a day) No identifiable trigger
Premonitory symptoms	Longer duration (>5 sec) Palpitations Blurred vision Nausea Warmth Diaphoresis Lightheadedness	Shorter duration (<6 sec) Palpitations less common	Sudden onset or brief aura (déjà vu, olfactory, gustatory, visual)	Usually absent
Observations during the event	Pallor Diaphoresis Dilated pupils Slow pulse, low BP Incontinence may occur Brief clonic movements may occur	Blue, not pale Incontinence may occur Brief clonic movements may occur	Blue face, no pallor Frothing at the mouth Prolonged syncope (duration >5 min) Tongue biting Horizontal eye deviation Elevated pulse and BP Incontinence more likely* Tonic-clonic movements if grand mal	Normal color Not diaphoretic Eyes closed Normal pulse and BP No incontinence Prolonged duration (minutes) common
Residual symptoms	Residual symptoms common Prolonged fatigue common (>90%) Oriented	Residual symptoms uncommon (unless prolonged unconsciousness) Oriented	Residual symptoms common Aching muscles Disorientation Fatigue Headache Slow recovery	Residual symptoms uncommon Oriented

*May be observed with any of these causes of syncope but more common with seizures.
BP, Blood pressure.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

response who may benefit from implantation of a permanent pacemaker. The test is contraindicated in patients with recent stroke, MI, and severe coronary or carotid disease.
- It is performed by keeping the patient strapped in an upright posture on a tilt table with footboard support. The angle of the tilt table varies from 60 to 80 degrees. The duration of upright posture during tilt-table testing varies from 25 to 45 min.
- The hallmark of neurocardiogenic syncope is severe hypotension associated with a paradoxic bradycardia triggered by a specific stimulus. The diagnosis of neurocardiogenic syncope is likely if upright tilt testing reproduces these hemodynamic changes in <15 min and causes presyncope or syncope.
- Postural orthostatic tachycardia syndrome is diagnosed if there is a sustained heart rate increase of not less than 30 beats/minute or above 120 beats/min within 10 min of active standing or head-up tilt without associated orthostatic hypotension and with reproduction of symptoms.

PSYCHIATRIC EVALUATION

- May be indicated in young patients without heart disease who have frequently recurring transient loss of consciousness and other somatic symptoms.
- Generalized anxiety disorder, pain disorder, and major depression predispose patients to neurally mediated reactions and may result in syncope.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Ensure proper hydration; consider compression stockings and salt tablets in appropriate patients.
- Eliminate medications that may induce hypotension.
- Elevate the head of the bed by 10 to 30 degrees while sleeping.

ACUTE GENERAL Rx

- Varies with the underlying etiology of syncope (e.g., pacemaker in patients with syncope resulting from complete heart block). Clinical variables for identification of high-risk syncope patients who may benefit from hospitalization or an accelerated outpatient evaluation are summarized in Table E3.
- Syncope caused by orthostatic hypotension is treated with volume replacement in patients with intravascular volume depletion. Also consider midodrine to promote venous return by adrenergic-mediated vasoconstriction and fludrocortisone for its mineralocorticoid effects to increase intravascular volume, although these medications can cause supine hypertension. Droxidopa is approved for neurogenic orthostatic hypotension in pure autonomic failure or multiple system atrophy.

DISPOSITION

Prognosis varies with the age of the patient and the etiology of the syncope. In general:
- Benign prognosis (very low 1-yr morbidity rate) in patients:
  1. Age <30 yr and having noncardiac syncope
  2. Age <70 yr and having vasovagal or psychogenic syncope or syncope of unknown cause
- Poor prognosis (high mortality and morbidity rates) in patients with cardiac syncope, with presenting systolic BP <90 mm Hg.
- Patients with the following risk factors have a higher 1-yr mortality rate: Abnormal ECG, history of ventricular arrhythmia, history of congestive heart failure.

REFERRAL

Hospital admission in elderly patients without prior history of syncope or unknown etiology of their syncope and in any patients suspected of having cardiac syncope, with presenting systolic BP <90 mm Hg.

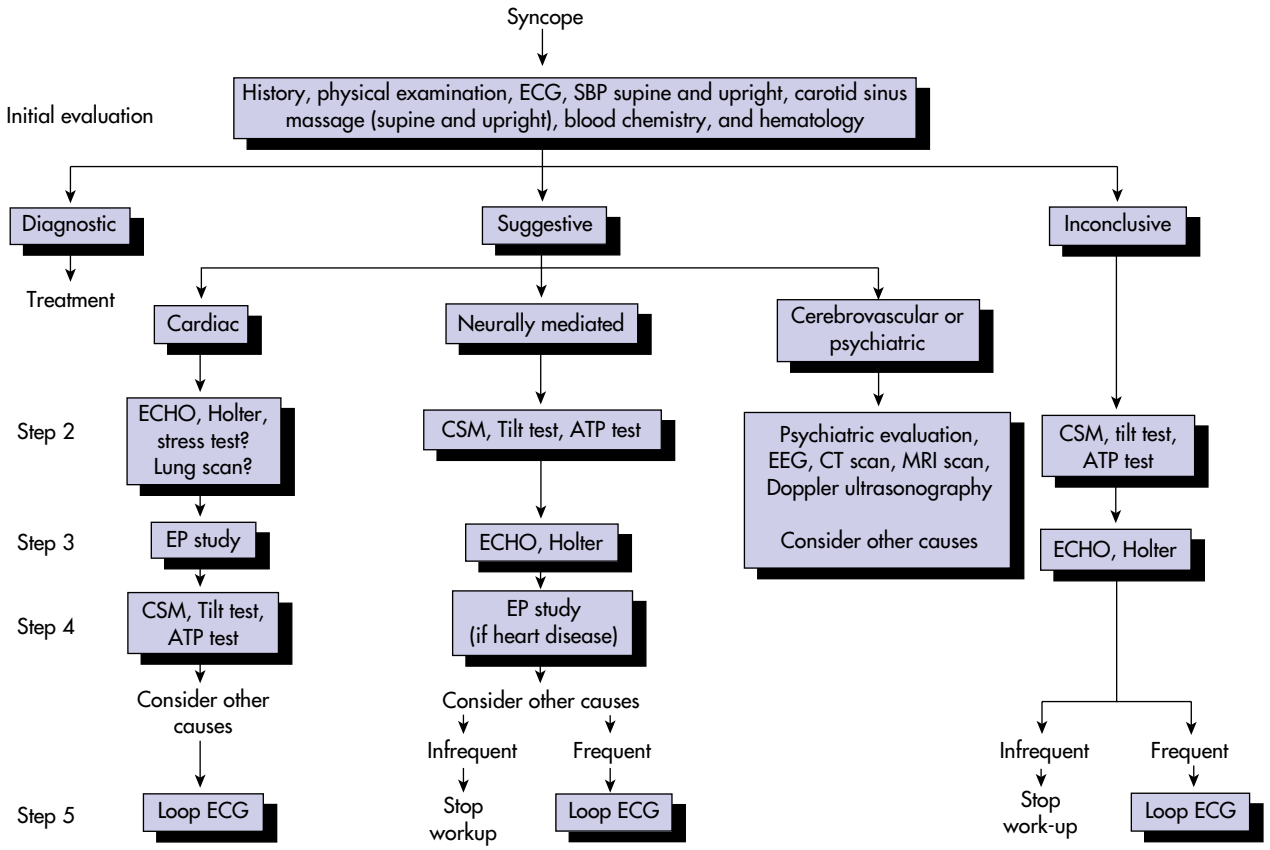

FIG. 2 An approach to the evaluation of syncope for all age groups. *ATP test,* Adenosine provocation test; *CSM,* carotid sinus massage; *ECG,* electrocardiogram; *ECHO,* echocardiogram; *EEG,* electroencephalography; *EP study,* electrophysiologic study; *SBP,* systolic blood pressure. (Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.)

PEARLS & CONSIDERATIONS

COMMENTS

- The etiology of syncope is identified in <50% of cases during the initial evaluation.
- A thorough history and physical examination are the most productive means of establishing a diagnosis in patients with syncope.
- Driving restrictions vary based on state but consider restricting driving if syncope is frequent or unpredictable.

TABLE E3 Clinical Variables for Identification of High-Risk Syncope Patients Who May Benefit from Hospitalization or an Accelerated Outpatient Evaluation

Severe structural heart disease (low ejection fraction, previous myocardial infarction, heart failure)
Clinical or ECG features suggesting arrhythmic syncope:
Syncope during exertion or while supine
Palpitations at the time of syncope
Family history of sudden death
Nonsustained ventricular tachycardia
Bifascicular block or QRS >120 msec
Severe sinus bradycardia (<50 beats/min) in the absence of medications or physical training
Preexcitation
Prolonged or very short QT interval
Brugada ECG pattern (right bundle branch block with ST elevation in leads V1-V3)
Arrhythmogenic right ventricular dysplasia ECG pattern (T wave inversion in leads V1-V3 with or without epsilon waves)
ECG suggestive of hypertrophic dilated cardiomyopathy
Clinical evidence or suspicion of a pulmonary embolus (clinical setting, sinus tachycardia, shortness of breath)
Severe anemia
Important comorbid conditions:
Significant electrolyte abnormalities
Severe anemia

ECG, Electrocardiogram.

BASIC INFORMATION

DEFINITION

In healthy individuals, the expected physiologic response to serum hypotonicity is inhibition of antidiuretic hormone/arginine vasopressin (ADH/AVP) hypothalamic synthesis and posterior pituitary gland release. Decreased binding to renal medullary collecting duct vasopressin (V2) receptors results in the increased excretion of urine that is dilute (low osmolality) and hypotonic (low sodium and potassium concentrations). The syndrome of inappropriate antidiuresis (SIAD) is defined by "inappropriately" concentrated urine in patients with hypotonic hyponatremia and normal extracellular fluid (ECF) volume. In the absence of an elevated serum glucose or exogenous osmole such as mannitol, the serum sodium concentration (S_{Na}) is determined primarily by the ratio of total body exchangeable sodium plus potassium (Na + K) (mmol) to total body water (TBW) (L):

$$S_{Na} = \frac{(Na + K)e}{TBW}$$

Hyponatremia results from a reduction of the numerator, increase of the denominator, or both. To correct hyponatremia, the normal, appropriate renal response is excretion of urine with [Na] + [K] concentrations that are significantly less than S_{Na}. In SIAD, TBW is increased primarily by expansion of the volume of electrolyte-free water (EFW), or water that essentially contains neither sodium nor potassium or any other electrolyte. The presence of urea in electrolyte-free water does not change tonicity. The severity of hyponatremia in SIAD reflects a defect of urinary dilution and the magnitude of electrolyte-free fluid intake. The definition of SIAD excludes hemodynamic stimuli that stimulate ADH, including ECF volume (decreased total body sodium content), hypotension, and disorders characterized by decreased effective arterial blood volume. The latter group is characterized by increased ECF volume (edema or ascites) from increased total body sodium content. This group includes cardiac disease (e.g., congestive heart failure or chronic pericardial disease), nephrotic syndrome, and cirrhosis.

The term *syndrome of inappropriate antidiuretic hormone* (SIADH) has fallen into disfavor because 10% to 15% of so-called SIADH patients manifest suppressed or undetectable serum ADH concentrations. The group with suppressed ADH may have increased sensitivity of renal collecting duct cells to ADH, secretion of other ADH-like peptides, or altered renal hemodynamics that reduce sodium and water delivery to distal diluting sites, thereby preventing maximal urinary dilution. Establishing a diagnosis of SIAD does not require the measurement of ADH levels. Patients with hypothyroidism and adrenal insufficiency are excluded from the definition of SIAD. SIAD is not diagnosed in acute or chronic kidney disease. However, thiazide-induced hyponatremia is considered a drug-induced form of SIAD or SIAD-type physiology. Drugs that decrease electrolyte-free water excretion also may cause SIAD and represent a separate diagnostic entity.

SYNONYMS

SIADH
SIAD
Syndrome of inappropriate antidiuretic hormone secretion
Syndrome of inappropriate ADH release
Inappropriate secretion of antidiuretic hormone

ICD-10CM CODE
E22.2 Syndrome of inappropriate secretion of antidiuretic hormone

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Hyponatremia occurs in nearly 14% of hospitalized patients and represents an acquired disorder in the majority of cases. Nearly half of these patients have SIAD. The adjusted odds ratio for in-hospital mortality in patients with hyponatremia at hospital admission is 1.47 (95% Confidence Interval, 1.33 to 1.62).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Chronic hyponatremia is defined as an S_{Na} <130 mmol/L persisting for more than 48 hours with normal ECF volume. Patients are hemodynamically stable with no evidence of edema, ascites, pleural, or pericardial effusion.
- Manifestations: Marathon running or other extreme endurance exercise, fever and delirium after 3,4-methylenedioxy-methamphetamine (MDMA, ecstasy) administration, stigmata of alcoholism or malnutrition, fever and/or localizing symptoms related to pneumonia or other pulmonary disease, or headaches and visual field defects from an intracranial mass.
- If hyponatremia occurs rapidly, generally in less than 24 h, delirium, lethargy, or seizures may occur. Diminished reflexes and extensor plantar responses may occur with severe hyponatremia or an S_{Na} <120 mmol/L.
- Neurologic abnormalities, including ataxia, mood changes, and proximal muscle weakness, are frequent in chronic hyponatremia. Abnormalities may be subtle, despite severe hyponatremia.
- Drugs: Thiazide diuretics and selective serotonin reuptake inhibitor (SSRI) antidepressants are the two most common causes of drug-related hyponatremia. Narcotic analgesics, carbamazepine, phenothiazines, tricyclic antidepressants, MDMA (ecstasy), nicotine, clofibrate, haloperidol, nonsteroidal antiinflammatory drugs (NSAIDs), monoamine oxidase inhibitors, chlorpropamide, vasopressin, desmopressin, oxytocin, and chemotherapeutic agents (vincristine, vinblastine, cyclophosphamide) represent additional etiologies.
- Neoplasms: Lung, oropharynx, stomach, duodenum, pancreas, brain, thymus, bladder, prostate, endometrium, mesothelioma, lymphoma, and Ewing sarcoma.
- Pulmonary disorders: Pneumonia, aspergillosis, pulmonary abscess, tuberculosis, bronchiectasis, emphysema, cystic fibrosis, status asthmaticus, and respiratory failure associated with positive-pressure breathing.
- Intracranial pathology: Trauma, neoplasms, infections (meningitis, encephalitis, brain abscess), hemorrhage, hydrocephalus, multiple sclerosis, and Guillain-Barré syndrome.
- Postoperative period: Surgical stress, positive pressure ventilation, anesthetic agents, and pain.
- Other: Acute intermittent porphyria, psychosis, delirium tremens, general anesthesia, and endurance exercise.
- Table 1 summarizes common etiologies of SIAD.

DIFFERENTIAL DIAGNOSIS

- Hyponatremia associated with subclinical hypovolemia
- Solute-limited water excretion (e.g., "tea-and-toast" diet, beer-drinker's potomania). This is an acquired disorder and is the renal inability to excrete sufficient electrolyte-free water due to an insufficient osmolar intake (sodium and potassium) and/or metabolism (generation of urea from protein metabolism).
- Primary polydipsia or water intake that exceeds renal dilutional capability and is frequently accompanied by solute-limited water excretion
- Endocrine disorders, including hypothyroidism and adrenal insufficiency
- Severe hypokalemia occurs because the pool of exchangeable potassium ions is twice the size of the exchangeable sodium pool. When intracellular potassium is in severe deficit, sodium ions exit the plasma, enter cells, and cause hyponatremia.
- Hypertonic hyponatremia (hyperglycemia, iatrogenic administration of mannitol, sorbitol, glycine)
- Hyponatremia from subclinical heart or liver disease
- Pseudohyponatremia caused by extreme hyperglobulinemia or hyperlipidemia
- Reset osmostat: Regulation of ADH occurs at a lower-than-normal osmotic threshold, with intact urinary dilution and concentration

WORKUP

- Normal ECF volume by history and physical examination. No history of large-volume fluid losses. No generalized edema, ascites, or large pleural effusions.
- Laboratory evaluation (see "Laboratory Tests") is consistent with excessive ADH secretion or sensitivity in the absence of osmotic or hemodynamic stimuli for ADH secretion.
- Normal thyroid, adrenal, and cardiac function.
- No recent or concurrent use of loop diuretics.
- Failure to correct hyponatremia after ECF volume repletion by isotonic 0.9% saline solution.
- Correction of hyponatremia by solely fluid restriction is generally unsuccessful.
- Diagnostic criteria for SIADH are described in Table 2.

TABLE 1 Common Etiologies of the Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH)

Tumors

Pulmonary/mediastinal (bronchogenic carcinoma, mesothelioma, thymoma)

Extrapulmonary (duodenal carcinoma, pancreatic carcinoma, ureteral/prostate carcinoma, uterine carcinoma, nasopharyngeal carcinoma, leukemia)

Central Nervous System Disorders

Mass lesions (tumors, brain abscesses, subdural hematoma)

Inflammatory diseases (encephalitis, meningitis, systemic lupus erythematosus, acute intermittent porphyria, multiple sclerosis)

Degenerative/demyelinating diseases (Guillain-Barré syndrome, spinal cord lesions)

Miscellaneous (subarachnoid hemorrhage, head trauma, acute psychosis, delirium tremens, pituitary stalk section, transsphenoidal adenomectomy, hydrocephalus)

Drug-Related

Stimulated release of AVP (nicotine, phenothiazines, tricyclics)

Direct renal effects and/or potentiation of AVP antidiuretic effects (desmopressin, oxytocin, prostaglandin synthesis inhibitors)

Mixed or uncertain actions (ACE inhibitors, carbamazepine and oxcarbazepine, chlorpropamide, clofibrate, clozapine, cyclophosphamide, 3,4-methylenedioxy-methamphetamine (ecstasy), omeprazole; serotonin reuptake inhibitors (SSRIs), vincristine

Pulmonary

Infections (tuberculosis, acute bacterial and viral pneumonia, aspergillosis, empyema)

Mechanical/ventilatory causes (acute respiratory failure, COPD, positive-pressure ventilation)

Other Causes

Acquired immunodeficiency syndrome (AIDS) and AIDS-related complex

Prolonged strenuous exercise (marathon, triathlon, ultramarathon, hot-weather hiking)

Senile atrophy

Idiopathic

ACE, Angiotensin-converting enzyme; *AVP,* arginine vasopressin; *COPD,* chronic obstructive pulmonary disease.
From Melmed S: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.

TABLE 2 Diagnostic Criteria for the Syndrome of Inappropriate Antidiuretic Hormone Release

Essential Diagnostic Criteria

Decreased extracellular fluid effective osmolality (<270 mOsm/kg H_2O)
Inappropriate urinary concentration (>100 mOsm/kg H_2O)
Clinical normovolemia
Elevated urinary sodium concentration under conditions of normal salt and water intake
Absence of adrenal, thyroid, or pituitary insufficiency
Absence of chronic kidney disease
Absence of diuretic use

Supplemental Criteria

Abnormal water loading test (inability to excrete at least 90% of a 20 ml/kg H_2O load in 4 hours and/or failure to dilute urine osmolality to <100 mOsm/kg H_2O)
Plasma vasopressin level inappropriately elevated relative to the plasma osmolality
No significant correction of S_{Na} with volume expansion, but improvement after fluid restriction

S_{Na}, Serum sodium.
From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

LABORATORY TESTS

- Normal or low BUN and/or serum creatinine
- Normal thyroid stimulating hormone
- S_{Na} lower than the limit of the normal range
- Decreased serum osmolality (<275 mOsm/kg H_2O) corrected for serum glucose and exogenous osmoles
- Decreased serum uric acid
- Urine osmolality >100 mOsm/kg H_2O with plasma hypotonicity
- Urine sodium usually >40 mmol/L with normal dietary salt intake

IMAGING STUDIES

Imaging is not routinely required for diagnosis. Imaging may facilitate the diagnosis of an associated underlying pulmonary or CNS disease or rule out intracranial pathology.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

With mild SIAD, fluid restriction (10 to 15 ml/kg/day) combined with increased solute loads (diets high in protein, urea powder, sodium chloride, and potassium chloride) may normalize S_{Na}. The enhanced solute load produces an osmotic diuresis that increases electrolyte-free water loss. Urea administration should be undertaken with a consulting nephrologist; it has been proven safe for decades.

ACUTE GENERAL Rx

PHARMACOLOGIC THERAPY:

Rate of Correction: In chronic hyponatremia, rapid S_{Na} correction rates are avoided to prevent brain injury from osmotic demyelination syndrome. Patients with moderate-to-severe hyponatremia should undergo serial monitoring of S_{Na} and serum potassium concentration (S_K), urine volumes, and urine chemistries (osmolality, K, and Na). Most SIAD patients have chronic hyponatremia (developing over more than 24 hours) and mild symptoms. Target S_{Na} correction rates are 6 to 8mmol/L/day in chronic hyponatremia. The S_{Na} should be actively lowered in patients who experience increases of >10 mmol/L during a 24-hour period. The rate of S_{Na} change during conservative therapy or 0.9% infusion should be slow or even flat because sodium is excreted while water is mostly retained. In cases of hyponatremia from undiagnosed ECF volume depletion or unrecognized limitation of EFW excretion because of inadequate urinary solute (tea and toast diet or beer potomania), the administration of saline may produce rapid excretion of large volumes of hypotonic urine with overly rapid S_{Na} correction. Therefore, close monitoring of serum and urine electrolytes, osmolality, and volume is recommended.

Acute Hyponatremia: In the small fraction of patients with acute hyponatremia (duration <24 hours), the goal of therapy is to increase S_{Na} sufficiently to prevent or reduce the severity of cerebral edema. S_{Na} should be increased by up to 6 mmol/L within the first 3 hours if symptoms are mild-to-moderate and within the initial hour with severe symptoms (seizures, coma, obtundation).

Rapid correction of S_{Na} in acute hyponatremia may involve hypertonic saline therapy (3% saline, 513 mmol/L). As a rule of thumb, 1 ml/kg body weight of 3% saline is expected to increase S_{Na} by 1mmol/L. Rates of S_{Na} correction may be greater than anticipated when unrecognized ECF volume depletion is concurrently corrected. The simultaneous delivery of the synthetic ADH analog desmopressin can mitigate S_{Na} overcorrection. Intravenous furosemide therapy may augment urinary EFW loss and prevent unintended ECF volume expansion during hypertonic saline therapy.

Chronic Hyponatremia: The therapeutic goals of chronic hyponatremia from SIAD are normalization of TBW and restoration of sodium and potassium stores to their respective normal levels. These goals may be achieved in the following manner:

- Choose a 24-hour target S_{Na} based on current S_{Na} and safe rates of correction (see "Rate of Correction").
- Estimate current TBW and total body cation content. Estimation of current TBW should consider the patient's baseline TBW, volume of additional retained water, and changes in total body content of sodium and potassium.
- Determine target TBW that achieves the target S_{Na} from Step 1.
- Determine 24-hour net EFW loss to attain the TBW from Step 3.
- Estimate and total all sources of EFW intake and loss (including insensible). Add/subtract this total volume to/from net target EFW (Step 4) to determine total EFW volume loss required to attain the target S_{Na}.
- Select an appropriate strategy to achieve the target EFW volume loss: Collecting duct V2 receptor antagonist (e.g., tolvaptan), urea therapy, or loop diuretic combined with electrolyte replacement such as sodium chloride ("salt") tablets.

The following example demonstrates the method to determine the target TBW and EFW loss required to reach an appropriate S_{Na} target after 24 hours of therapy for a patient with chronic hyponatremia:

- S_{Na} is 115 mmol/L in 75kg, minimally symptomatic elderly woman who chronically takes an SSRI and hydrochlorothiazide.
  1. *Step 1: Establish target S_{Na}:*
     a. Target S_{Na} after 24 hours = Current S_{Na} + 6 = 121 mmol/L
  2. *Step 2: Estimate current TBW and total body cations:*
     a. Current weight = 75 kg
     b. Estimated TBW fraction = 0.55 (55%)
     c. Current TBW = 0.55 × 75 = 41.2 L
     d. Current total body cation quantity = Current TBW × S_{Na} = 41.2 × 115 = 4743 mmol
  3. *Step 3: Calculate target TBW:*
     a. Target TBW (L) = Current Na and K cation/Target S_{Na} = 4743 mmol/121 mmol/L = 39.2 L
  4. *Step 4: Calculate net EFW loss:*
     a. Target *net EFW loss* after 24 hours = Current TBW – Target TBW = 41.2 L – 39.2 L = 2 L
  5. *Step 5: Calculate total urine EFW volume:*
     a. Target *total urine EFW excretion* (estimate: 1 L oral fluid intake and 0.5 L net insensible loss) Urine EFW volume = 2 + (1 – 0.5) = 2.5 L
  6. *Step 6: Establish therapeutic strategy*
  7. *Step 7: Implementation strategy*
- From Step 6, a 24-hour net EFW loss of 2.5 L is required. With loop diuretic administration, this volume of EFW loss entails an equal volume of isotonic cation loss for a 5L urine output. Cation losses can be repaired with 0.9% saline or 3% saline. Administration of the latter requires 70% less volume than 0.9% saline and elevates S_{Na} more rapidly. Alternatively, cation replacement can be carried out by oral administration of NaCl and KCl tablets. Periodic monitoring of S_{Na}, S_K, urine volume, and urine chemistries (osmolality, sodium, and potassium) is recommended to prevent overly rapid correction of S_{Na}.

Loop Diuretic Plus Saline Strategy: Before the advent of specific V2 receptor antagonists, SIAD was typically treated by increasing urine volume and EFW loss with a loop diuretic. Half of the urine volume can be assumed to consist of electrolyte-free water because the sum of urine sodium and potassium cation concentrations will approximate 75 mmol/L, i.e, half-normal saline concentration. Isotonic or hypertonic IV fluids can be administered to correct urine sodium loss. A 1L volume 0.9% saline is equivalent to 0.3 L of 3% saline. Its use should be guided by an expert. Urine potassium loss must not be ignored and corrected separately.

Vasopressin (V2) Receptor Antagonists: Selective V2 receptor antagonist therapy is straightforward and convenient for patients and medical personnel. Two agents are available in the U.S.: IV conivaptan (20 mg IV × 1 followed by continuous IV infusion of 20 to 40 mg/day for 2 to 4 days) and oral tolvaptan (15 to 90 mg/day, as needed). Tolvaptan must be initiated in-hospital. Urinary electrolyte losses are minimal, meaning that administration produces virtually electrolyte-free urine (Step 5).

CHRONIC Rx

- When SIAD is chronic, fluid restriction (<15 ml/kg) may be required indefinitely and combined with high dietary electrolyte and protein.
- NaCl tablets, electrolyte supplements, protein powders to generate urea production, and pharmaceutical-grade urea may be used to correct hyponatremia. Periodic monitoring of electrolytes is recommended in patients with chronic SIAD.
- Tolvaptan has been administered successfully in clinical trials. FDA-labeling states that initial therapy must take place in-hospital. Tolvaptan use is restricted to 30 days due to concerns regarding hepatotoxicity, which was detected during clinical trials for polycystic kidney disease. Additional contraindications include volume contraction and concomitant use of strong cytochrome P3A inhibitors. Patients undergoing tolvaptan therapy should not be fluid-restricted.
- Demeclocycline variably increases urine electrolyte-free water losses. This agent is contraindicated in hepatic disease and rarely is used today.

DISPOSITION

- Mortality exceeding 40% has been reported in patients with S_{Na} <110 mmol/L.
- Hospital readmission rates are common in chronic SIAD when an underlying cause cannot be eliminated, especially if patients are unwilling or unable to restrict their fluid intake and follow dietary recommendations.
- Chronic, mild-to-moderate hyponatremia is associated with bone loss, falls, and increased fracture risk, particularly in elderly patients.

REFERRAL

Emergency department evaluation and hospital admission are appropriate for moderate-to-severe hyponatremia due to SIAD, especially when acute or symptomatic. Due to a high complication risk from overly aggressive or ineffective treatment, consultation by a nephrologist, endocrinologist, or critical care physician is recommended.

Synthetic Cannabinoids

BASIC INFORMATION

DEFINITION

Synthetic cannabinoids are manufactured variants of natural cannabinoids found in marijuana. Most are modeled after delta-9-tetrahydrocannabinol (THC), which is among the most psychoactive of the cannabinoids. The chemical structures of these substances are frequently altered in order to circumvent regulations and law enforcement. They often are sold as incense or herbal products combined with various other herbal ingredients.

SYNONYMS

There are more than 700 commonly used synonyms for synthetic cannabinoids.
Chill out
Chill x
Crazy monkey
Herbs
Incense
K2
Spice
Spice diamond
Spice gold

ICD-10CM CODES	
F12.1	Cannabis abuse
F12.15	Cannabis abuse with psychotic disorder
F12. 98	Cannabis use, unspecified with other cannabis-induced disorder
F19.1	Other psychoactive substance abuse

EPIDEMIOLOGY & DEMOGRAPHICS

- Synthetic cannabinoids were developed in research laboratories in the 1980s and first emerged as a recreational drug around 2008.
- Prevalence and incidence have steadily increased, with over 7000 annual cases reported to regional poison control centers in the U.S.
- The majority of exposures occur in young men aged 20 to 30 yr as a result of intentional ingestion as a recreational drug. Adolescents 13 to 18 yr account for up to 25% of hospitalizations after ingestions.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Synthetic cannabinoids are manufactured experimentally, with each variation carrying a new chemical signature. Frequently they are sold as a mixture with various herbs and other compounds. As such, physical symptoms may vary widely depending upon the route and type of substance ingested.
- The majority of symptoms are mild and self-limited; however, severe toxicities are common.
- Synthetic cannabinoids have much higher potency than natural marijuana, and thus greater potential for delirium, agitation, and psychosis.
- The most common symptoms across multiple studies are sinus tachycardia and neuropsychiatric symptoms (toxic psychosis, agitation, coma, CNS symptoms).
- Among the most commonly reported symptoms are:
  1. Tachycardia, palpitations, chest pain, hypotension, bradycardia, cardiac arrest
  2. Conjunctival injection, nystagmus, ataxia, sedation, seizures, syncope, respiratory depression, CNS depression, coma, emesis, hyperthermia, rhabdomyolysis, acute kidney injury
  3. Psychotic effects: Irritability, paranoia, anxiety, racing thoughts, hallucinations, delusions, psychosis, delirium
- There have been reports of myocardial infarction, subarachnoid hemorrhages, pneumothorax, and acute ischemic strokes after ingestion. Superwarfarin adulterants of synthetic cannabinoids can lead to clinically significant coagulopathy.[1]

ETIOLOGY

- The majority of synthetic compounds are cannabinoid receptor 1 and 2 (CB1 and CB2) agonists. Some versions have NDMA, serotonin, and other receptor affinity.
- Current compounds have higher cannabinoid receptor binding affinity, with resulting potency up to 800 times greater than THC.
- Metabolized by glucuronidation and oxidation by liver cytochrome oxidase enzymes and renally excreted.

DIAGNOSIS

- Intoxication with synthetic cannabinoids is primarily a clinical diagnosis.
- Rapid urine drug screens designed to detect THC will not detect the presence of synthetic cannabinoids.
- Mass spectrometry and liquid chromatography can confirm the presence of synthetic compounds but have limited use in the timely treatment of the acutely toxic patient.

DIFFERENTIAL DIAGNOSIS

- Drug or alcohol intoxication
- Hypoglycemia
- Acute psychosis
- Status epilepticus or seizure disorder
- Toxidromes (tricyclic antidepressants, anticholinergic agents, organophosphates, sympathomimetics)

WORKUP

The diagnosis of synthetic cannabinoid intoxication is clinical. Workup is dictated by clinical symptoms and degree of toxicity.

LABORATORY TESTS

- Mild intoxication usually does not require extensive laboratory studies.
- For severe toxicity:
  1. Serum electrolytes
  2. Blood urea nitrogen and creatinine, as there is increased risk for acute kidney injury
  3. Creatine kinase and urine myoglobin if concern for rhabdomyolysis
  4. Venous blood gas if concern for respiratory depression
  5. Serum lactate for increased risk of lactic acidosis
  6. Drug abuse screen for contaminants or coingestions
  7. Troponin or cardiac biomarkers, as there is increased risk for myocardial infarction in patients with chest pain

IMAGING STUDIES

Neuroimaging (CT or MRI of the brain) would be indicated if seizure is part of toxidrome.

OTHER TESTS

12-Lead electrocardiogram

TREATMENT

Treatment is supportive and directed at symptoms and complications of toxicity.

- Acute kidney injury is common. Fluid resuscitation should be started for the prevention and treatment of renal injury and rhabdomyolysis in most patients.
- Reassurance, decreased stimulation in a dimly lit room, and benzodiazepines for anxiety are useful in mild-to-moderate toxicity.
- Psychosis and agitation can usually be adequately controlled with benzodiazepines.
- Hyperthermia from seizures, myoclonus, and rhabdomyolysis should be treated aggressively. Evaporative cooling, benzodiazepines, and cooling blankets are usually sufficient.
  1. If intubation and paralysis are necessary, depolarizing agents such as succinylcholine should be avoided, as hyperkalemia from rhabdomyolysis is of concern.
  2. Antipyretics have no effect in temperature management.
- Seizures should be treated with benzodiazepines. Frequently, seizures are reported as a single nonsustained episode. Seizures unresponsive to benzodiazepines should be treated with pharmacologically induced coma and continuous EEG. Neuroimaging is recommended in patients with seizures.
- Dystonic symptoms are best treated with benzodiazepines rather than with anticholinergic agents such as diphenhydramine, which have the potential to worsen hyperthermia.
- Early administration of haloperidol in addition to antiemetics for the treatment of cannabinoid hyperemesis syndrome.

[1]Kelkar AH et al: An outbreak of synthetic cannibinoid-associated coagulopathy in Illinois, *N Engl J Med* 379:1216-1223, 2018.

NONPHARMACOLOGIC THERAPY

Counseling addressing psychological and social issues

DISPOSITION

- Patients with mild-to-moderate symptoms can be observed for 6 hr in the emergency department and safely discharged after resolution of symptoms.
- Patients who remain symptomatic warrant admission to an appropriate level of care, based on the severity of their symptoms.

BASIC INFORMATION

DEFINITION

Syphilis is a systemic sexually transmitted disease caused by the bacteria *Treponema pallidum*, with acute and chronic manifestations, characterized by primary skin lesions; secondary eruption involving skin and mucous membranes; long periods of latency; and late lesions of the skin, bone, viscera, central nervous system, and cardiovascular system.

SYNONYM

Lues

ICD-10CM CODES

A50	Congenital syphilis
A51.0	Primary genital syphilis
A51.1	Primary anal syphilis
A51.2	Primary syphilis of other sites
A51.3	Secondary syphilis of skin and mucous membranes
A51.4	Other secondary syphilis
A51.5	Early syphilis, latent
A51.9	Early syphilis, unspecified
A52	Late syphilis
A52.0	Cardiovascular and cerebrovascular syphilis
A52.1	Symptomatic neurosyphilis
A52.2	Asymptomatic neurosyphilis
A52.3	Neurosyphilis, unspecified
A52.8	Late syphilis, latent
A52.9	Late syphilis, unspecified
A53.9	Syphilis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Most commonly diagnosed in people 20 to 30 yr old.
- Slightly more prevalent in men than women.
- Rates reached historic lows in the U.S. in 2000 but began increasing among males in 2001, and increase has continued. The number of cases reported to the CDC increased by 71% from 2014 to 2018. In 2018 men accounted for 86% of all patients with syphilis. Rates are disproportionately higher among black and Hispanic men who have sex with men (MSM), compared with white MSM and among young MSM. Rates are also increasing in women, with highest rates in black women compared with Hispanic and white women. The rates of primary and secondary syphilis among women more than doubled between 2014 and 2018. Congenital syphilis rates also have been increasing, with 1306 cases reported in 2018.
- Usually more prevalent in urban areas and among people of lower socioeconomic status.
- Communicability is indefinite and variable. Communicable during primary, secondary, and latent mucocutaneous lesions in up to first 4 yr of latency. Most probable congenital transmission occurs in early maternal syphilis. Adequate penicillin treatment ends infectivity within 24 to 48 hr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

PRIMARY SYPHILIS:

- Characteristic lesion is a painless chancre on genitalia (Figs. E1 and E2), mouth, or anus; atypical primary lesions may occur.
- May appear 3 days to 12 wk (usually 3 wk) after exposure and may resolve without treatment within 6 wk.

SECONDARY SYPHILIS:

- Bacteremia associated with generalized lymphadenopathy and a characteristic maculopapular rash including palms, soles, trunk, and mucous membranes. Lesions may also be pustular, involve the mucosal surfaces. Constitutional, flulike symptoms may also occur, as well as mild disturbances of multiple organ systems.
- 60% to 80% have maculopapular lesions on palms and soles (Fig. E3).
- 21% to 58% have mucocutaneous or mucosal lesions (pharyngitis, tonsillitis, "mucous patch" lesion on oral and genital mucosa).
- Condylomata lata intertriginous papules (raised, gray-white lesions) form at areas of friction and moisture, such as the vulva (Fig. E4).
- Occurs 4 to 6 wk after appearance of chancre. Resolves within 1 wk to 12 mo. Can have relapsing episodes up to 5 yr after initial episode.

LATENT SYPHILIS—EARLY VS. LATE LATENT:

- Generally asymptomatic, can occur between 1 and 30 yr after a primary infection
- Seroreactivity without other evidence of primary or secondary disease
- Not sexually transmitted but may be transmitted from a pregnant woman to her fetus for up to 4 yr after acquiring the disease
- In early latent syphilis, disease can be transmitted even without the current presence of an active lesion. This is not the case in late latent syphilis
- Early latent: <12 mo from acquisition
- Late latent: >12 mo from acquisition, or time since infection is unknown

TERTIARY SYPHILIS:

- A form of late syphilis characterized by gummas (nodular, ulcerative lesions) that can involve the skin, mucous membranes, skeletal system, and viscera.
- Manifestations of cardiovascular syphilis include aortitis, aneurysm, or aortic regurgitation.
- Neurosyphilis may be asymptomatic or symptomatic. Tabes dorsalis, meningovascular syphilis, general paralysis, or insanity may occur.
- Ocular syphilis can affect any part of the eye. Posterior uveitis is the most common. Iritis, choroidoretinitis, and leukoplakia may also occur.

ETIOLOGY

- *Treponema pallidum,* a spirochete
- Spread by sexual intercourse or by intrauterine transfer

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other genitoulcerative diseases such as herpes, chancroid (see Table 1)
- See Section III for a clinical algorithm for the evaluation of genital ulcer disease

WORKUP

Confirmation is primarily through laboratory diagnosis.

- Culture of lesions
- Serologic testing (see the following lab tests)
- Cerebrospinal fluid (CSF) testing

LABORATORY TESTS

- Dark-field microscopy of fluid from lesion to look for treponeme is the definitive method for diagnosis of early syphilis.
- Serologic testing:
  1. Nontreponemal tests: Venereal disease research laboratory (VDRL) or rapid plasma reagin (RPR).
  2. Treponemal tests: Fluorescent treponemal antibody absorbed (FTA-ABS) tests, the *T. pallidum* passive particle agglutination (TP-PA) assay, various enzyme immunoassays (EIAs), chemiluminescence immunoassays, immunoblots, or rapid treponemal assays.
  3. Antibody titers can assess for response to treatment and for reinfection in previously treated patients.
- Screening methods:

TABLE 1 Genital Ulcer Disease

Disease	Lesions	Lymphadenopathy	Systemic Symptoms
Primary syphilis	**Painless,** indurated, with a clean base, usually singular	Nontender, rubbery, nonsuppurative bilateral lymphadenopathy	None
Genital herpes	**Painful** vesicles, shallow, usually multiple	Tender, bilateral inguinal adenopathy	Present during primary infection
Chancroid	Tender papule, then **painful,** undermined purulent ulcer, single or multiple	Tender, regional, painful, suppurative nodes	None
Lymphogranuloma	Small, **painless** vesicle or papule progresses to an ulcer	Painful, matted, large nodes with fistulous tracts	Present after genital lesion heals

From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.

1. Traditional: Screen with nontreponemal tests; confirmation with treponemal testing.
2. Alternative: Screen with treponemal testing, confirm with nontreponemal testing. More false positives, less likely to miss early or latent syphilis.

- When the nontreponemal test is negative despite a positive screen, an additional treponemal screen may be helpful. Trials have shown that two positive treponemal screens help identify a population with likely prior or current syphilis, and treatment of these patients may be justifiable.
- In patients with neurosyphilis, serologic criteria for response to therapy is a fourfold or greater decrease in VDRL titer over 6 to 12 mo.
- Lumbar puncture (LP) for cerebrospinal fluid VDRL (CSF-VDRL) in patients with evidence of latent syphilis (good specificity, poor sensitivity). If negative with high suspicion, can also perform a CSF FTA-ABS (good sensitivity, less specificity). When reactive in the absence of substantial contamination of CSF with blood, it is considered diagnostic of neurosyphilis. The Centers for Disease Control and Prevention indications for LP are neurologic symptoms, treatment failure, any eye or ear involvement, or evidence of active syphilis (aortitis, gumma, iritis).
- HIV testing in all patients.

Rx TREATMENT

ACUTE GENERAL Rx

- Primary, secondary, early latent:
  1. Penicillin G benzathine 2.4 million U IM once.
  2. Infants and children: Benzathine penicillin G 50,000 units/kg IM, up to the adult dose of 2.4 million units in a single dose.
  3. Nonpregnant penicillin-allergic patients: Doxycycline 100 mg bid × 14 days.
  4. Alternative regimens (contraindicated in MSM, persons with HIV, or pregnant women):
     a. Azithromycin 2 g PO × 1 dose
     b. Ceftriaxone 1-2 g IM or IV for 10-14 days
     c. Tetracycline 500 mg PO QID for 14 days
     d. Amoxicillin 3 g PO BID + probenecid 500 mg PO BID for 14 days
  5. Careful clinical and serologic follow-up of persons receiving any alternative therapy is essential.
  6. Persons with a penicillin allergy whose compliance with therapy or follow-up cannot be ensured should be desensitized and treated with benzathine penicillin.
- Late latent syphilis, tertiary syphilis (not neurosyphilis):
  1. Penicillin G benzathine 2.4 million U IM q wk × 3 wk.
  2. Infants and children: Benzathine penicillin G 50,000 units/kg IM, up to the adult dose of 2.4 million units in a single dose.
  3. Nonpregnant penicillin-allergic patients: Doxycycline 100 mg PO BID × 4 wk.
- Neurosyphilis:
  1. Aqueous crystalline penicillin G 18 to 24 million U/day, administered as 3 to 4 million U IV q4h or continuous infusion for 10 to 14 days.
  2. Alternative regimen: Procaine penicillin 2.4 million U IM/day plus probenecid 500 mg PO qid, both for 10 to 14 days.
- Congenital syphilis:
  1. Aqueous crystalline penicillin G 50,000 U/kg/dose IV q12h × first 7 days of life and q8h after that for a total of 10 days OR procaine penicillin G 50,000 U/kg/dose IM/day × 10 days.
  2. An algorithm for evaluation and treatment of infants born to mothers with reactive serologic tests for syphilis is illustrated in Fig. E5.

DISPOSITION

- Repeat quantitative nontreponemal tests at 6 and 12 mo to ensure adequate treatment. For HIV-infected patients, repeat testing at 3, 6, 9, 12, and 24 mo. Pregnancy requires monthly tests until delivery.
- Findings indicating need for retreatment of syphilis and additional testing for HIV:
  1. If a fourfold increase in titer occurs and is sustained over testing performed >2 wk apart.
  2. If initial high titer fails to drop by fourfold within a yr for early syphilis or 24 mo for late syphilis
  3. If signs persist, or patient develops new signs of infection
- Because treatment failure may be the result of unrecognized CNS infection, CSF examination can be considered in such situations. For retreatment, weekly infusions of benzathine penicillin G 2.4 million units IM for 3 wk is recommended, unless CSF examination indicates that neurosyphilis is present.
- Pregnant women without a fourfold drop in titer by 6 mo compared to pretreatment titer need to be retreated. Inadequate treatment is likely if patient delivers fewer than 30 days after treatment, or if titers are fourfold higher than pretreatment at delivery. Titers should be repeated monthly during pregnancy for those infected.
- Cases should be reported to local or state health department for referral, follow-up, and partner notification.

REFERRAL

- Pregnant and possible congenital syphilis
- Pregnant and allergic to penicillin, who need to be desensitized for treatment
- Late latent syphilis with serious central nervous system, cardiovascular, or other organ system compromise

PEARLS & CONSIDERATIONS

- Jarisch-Herxheimer reaction (fever, myalgia, tachycardia, hypotension) may occur within 24 hr of treatment.
- Fig. E6 illustrates the course of untreated syphilis. One third of untreated patients develop CNS and/or cardiovascular sequelae.
- Up to 80% of those treated during late stages remain seropositive indefinitely.
- Treponemal tests remain positive even after adequate therapy.
- Male circumcision does not decrease the incidence of syphilis (unlike HIV, HSV-2, and HPV infection).
- Partner notification and treatment:
  1. Persons who are exposed within 90 days preceding the diagnosis of primary, secondary, or early latent syphilis in a sex partner might be infected even if seronegative; therefore, such persons should be treated presumptively.
  2. Persons who were exposed ≥90 days before the diagnosis of syphilis in a sex partner should be treated presumptively if serologic test results are not available immediately and the opportunity for follow-up is uncertain.

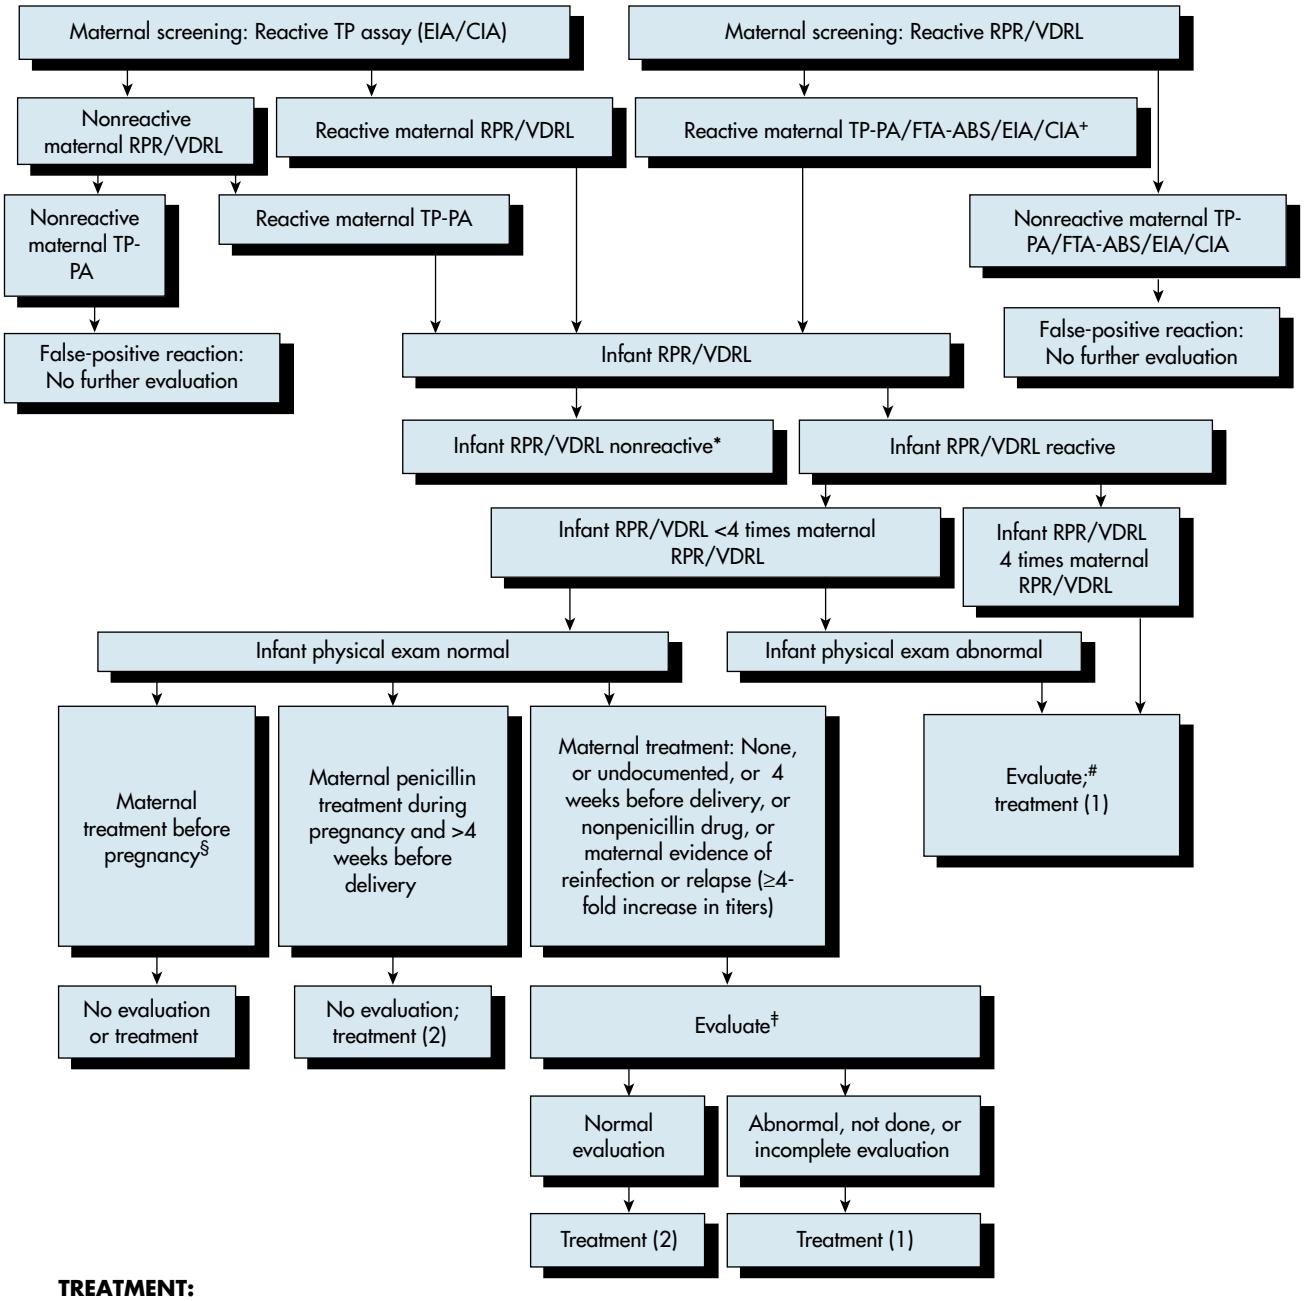
FIG. E4 Condyloma lata—genital lesions of secondary syphilis. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)



TREATMENT:

(1) Aqueous penicillin G 50,000 U/kg IV q 12 hr (1 wk of age), q 8 hr (>1 wk), or procaine penicillin G 50,000 U/kg IM single daily dose, x 10 days

(2) Benzathine penicillin G 50,000 U/kg IM x 1 dose

FIG. E5 Algorithm for evaluation and treatment of infants born to mothers with reactive serologic tests for syphilis. +, Test for HIV antibody. Infants of HIV-infected mothers do not require different evaluation or treatment. *If the mother has had no treatment, undocumented treatment, treatment ≤4 weeks before delivery, or evidence of reinfection or relapse (fourfold or higher increase in titers) *and* the infant's physical examination is normal, *then* treat infant with a single intramuscular injection of benzathine penicillin (50,000 U/kg). No additional evaluation is needed. §Women who maintain a VDRL titer ≤1:2 (RPR ≤1:4) beyond 1 year after successful treatment are considered serofast. #Evaluation consists of CBC, platelet count, CSF examination for cell count, protein, and quantitative VDRL. Other tests as clinically indicated: Long-bone x-rays, neuroimaging, auditory brain stem response, eye examination, chest radiograph, liver function tests. ‡CBC, platelet count; CSF examination for cell count, protein, and quantitative VDRL; long-bone radiographs. Treatment regimens are as follows: (1) aqueous penicillin G 50,000 units/kg IV every 12 hours (≤1 week old) or every 8 hours (>1 week old) or procaine penicillin G 50,000 units/kg IM single daily dose × 10 days; (2) benzathine penicillin G 50,000 units/kg IM × 1 dose. *CBC,* Complete blood count; *CIA,* chemiluminescence; *CSF,* cerebrospinal fluid; *EIA,* enzyme immunoassay; *FTA-ABS,* fluorescent treponemal antibody absorption; *IM,* intramuscular; *IV,* intravenous; *RPR,* rapid plasma reagin; *TP, Treponema pallidum; TP-PA, Treponema pallidum* particle agglutination; *VDRL,* Venereal Disease Research Laboratory. BASIC INFORMATION

DEFINITION

Syringomyelia is a condition characterized by the formation of any fluid-filled tubular cavity within the spinal cord. When syringomyelia involves the medulla oblongata, it is called syringobulbia, and when it involves the cerebral pons, it is described as syringopontia. When the cavity is in direct continuity with the fourth ventricle, it is called communicating syringomyelia. *Hydromyelia* is sometimes used as a term that indicates a focal dilatation of the spinal cord central canal.

SYNONYM

Syrinx

ICD-10CM CODES

G95.0 Syringomyelia, syringobulbia, and syringopontia
Q06.4 Hydromyelia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- A rare condition
- No accurate figures for the incidence of syringomyelia
- Incidence of posttraumatic syringomyelia is between 1.9% and 4.5%

PREVALENCE:

- Prevalence can vary from 1.9 per 100,000 people in Japan to 8.4 per 100,000 people in Western countries
- About 40% to 75% of patients with Chiari malformations have syringomyelia
- 90% of patients with syringomyelia have an associated Chiari malformation
- 50% of cases are due to cerebrospinal fluid (CSF) blockage
- 10% communicate with fourth ventricle

PREDOMINANT SEX AND AGE:

- Symptoms commonly begin in late adolescence or early adulthood
- Both sexes are equally affected

RISK FACTORS:

- Congenital defects such as neural tube defects (myelomeningocele and tethered cord syndrome), Chiari malformations, and Klippel-Feil syndrome
- Base of skull anomalies such as achondroplasia
- Spinal cord trauma, including birth trauma and postsurgical. More prevalent in a complete spinal cord injury. Diagnosed 12 to 15 years after spinal cord injury.
- Intramedullary tumors (ependymomas, astrocytomas, and hemangioblastomas are most common)
- Extramedullary tumors and arachnoid cysts
- Inflammatory conditions such as sarcoidosis, multiple sclerosis, and transverse myelitis
- Spinal arteriovenous malformations
- Spinal canal stenosis (cervical most common)
- Infection such as meningitis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Onset is usually insidious, often asymptomatic until the third or fourth decade
- More acute course if it involves the brain stem
- Cervical spine is the most commonly affected area:
  1. Neuropathic joints (Fig. E1) (especially in the shoulder or elbow), intrinsic hand atrophy, hand and/or arm weakness
  2. Neck, back, arm, and/or leg pain and stiffness
  3. Cape-like loss of pain and temperature in the upper extremity with preservation of light touch, vibration, and proprioception
  4. Painless burns or other injuries in the hand
  5. Sharp testing elicits no pain, but patient often perceives the sharpness of the object
  6. Impaired walking, toe walking in children
  7. Bowel and bladder dysfunction are signs of late-stage disease
  8. Loss of upper limb reflexes and hyperreflexia in the lower extremities
- Scoliosis is common, especially in children
- Nystagmus and Horner syndrome may also occur
- Hemangiomas or midline tuft of hair can indicate underlying spine deformities

ETIOLOGY

- Two current theories of syrinx development:
  1. Obstruction of CSF outflow from the fourth ventricle at the level of the foramen magnum
  2. Difference in spinal pressure and intracranial pressure during Valsalva-like maneuvers
- Congenital malformations, any acquired trauma, or spinal inflammatory/infection conditions could cause the abnormal CSF flow dynamics

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Amyotrophic lateral sclerosis/motor neuron disease
- Diabetic neuropathy
- Spinal cord tumor
- Spinal cord infarction
- Spinal cord epidural abscess
- Multiple sclerosis
- Transverse myelitis
- Tabes dorsalis
- Vitamin B_{12} deficiency

FIG. E1 Syringomyelia. A, A neuropathic wrist joint in a patient with mild syringomyelia. Note the swelling and deformity of the joint. **B,** Radiograph showing the gross destruction of the proximal carpal row with attrition and simplification of the bony margins. Residual fragments of bone and considerable soft tissue swelling also can be seen. **C,** Wasting of the intrinsic muscles of the hand and claw deformity. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

- Copper deficiency
- Progressive spinal muscular atrophy

IMAGING STUDIES

- Plain radiographs usually reveal widening of the bony canal in the region of involvement
- Bony anomalies are often present at the base of the skull and at the C1 to C2 spinal segments
- MRI (Fig. E2 and E3) of the spine with contrast is the gold standard study of choice. Gadolinium contrast is necessary to rule out spinal tumors
- Four-dimensional phase-contrast MRI can best evaluate CSF flow dynamics
- CT myelography is an alternative test if MRI is contraindicated

Rx TREATMENT

- No medical treatment is currently available
- Asymptomatic syringomyelia can be treated expectantly, as there have been cases of spontaneous resolution
- Decompressive laminectomy is standard of care for patients with normal CSF flow and mild neurologic symptoms
- Direct drainage of the syrinx by syringoarachnoid, syringoperitoneal, and synringopleural shunts
- Syringotomy
- Terminal ventriculostomy
- Neuroendoscopic surgery
- Cell transplantation with autologous bone marrow-derived mesenchymal stromal cells in symptomatic post-traumatic syringomyelia

DISPOSITION

- The condition is slowly progressive in most cases, but the course of the disease may be quite variable, ranging from death in a few months to slow incapacitation over several years; progression may halt at any time.
- Surgical intervention leads to improvement in neurologic findings in 30% of patients
- Physical and occupational therapies prevent further loss of function

REFERRAL

Neurology and neurosurgery referral when diagnosis is suspected

BASIC INFORMATION

DEFINITION

Systemic lupus erythematosus (SLE) is a chronic inflammatory disorder characterized by autoantibody production responsible for antibody-mediated and immune complex deposition tissue damage. SLE involves multiple organs and systems and has heterogeneous disease patterns. Relapses and remissions are a common feature.

SYNONYMS

SLE
Lupus

ICD-10CM CODES

M32	Systemic lupus erythematosus
M32.0	Drug-induced systemic lupus erythematosus
M32.8	Other forms of systemic lupus erythematosus
M32.9	Systemic lupus erythematosus, unspecified
M32.10	Systemic lupus erythematosus, organ or system involvement unspecified
M32.11	Endocarditis in systemic lupus erythematosus
M32.12	Pericarditis in systemic lupus erythematosus
M32.13	Lung involvement in systemic lupus erythematosus
M32.14	Glomerular disease in systemic lupus erythematosus
M32.15	Tubulo-interstitial nephropathy in systemic lupus erythematosus
M32.19	Other organ or system involvement in systemic lupus erythematosus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Varies across gender, race/ethnic groups, and geography from 20 to 70 cases per 100,000 persons. Prevalence higher among African Americans, Asian Americans, and Hispanics. There are an estimated 350,000 people with SLE in the U.S.
PREDOMINANT SEX: Female:male ratio is 9:1. The ratio is highest in reproductive age group, and about half of that in patients younger than 16 and older than 55.
PREDOMINANT AGE: Mean age at diagnosis is 31.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Constitutional: Unexplained fever, fatigue (80% to 100% patients), malaise (Table 1)
- Mucocutaneous lesions (more than 80% of patients): Acute (associated with + Ro antibody): malar rash (Fig. E1) sparing nasolabial folds (acute cutaneous lupus); annular or papulosquamous rash (subacute cutaneous lupus); Chronic: raised erythematous patches with subsequent edematous plaques and adherent scales (discoid cutaneous lupus), lupus profundus, lupus tumidus; alopecia, photosensitivity, nasal, or oropharyngeal ulcerations (classically painless, but discoid lesions [Fig. E2] may be painful); Raynaud phenomenon; leukocytoclastic vasculitis, chilblains; livedo reticularis or livedo racemosa (secondary to antiphospholipid antibody syndrome); skin biopsy hallmark: interface dermatitis
- Musculoskeletal (about 90% of lupus patients): Arthralgias are more common than true arthritis, but nonerosive deforming arthritis is not rare; myositis
- Cardiac: Pericardial rub (pericarditis) is most common; valvular heart disease: valve nodules and thickening (Libman-Sacks endocarditis); congestive heart failure, myocarditis, premature atherosclerotic heart disease
- Pulmonary: Pleuritis (most common), acute or chronic pneumonitis, diffuse alveolar hemorrhage, pulmonary hypertension
- Gastrointestinal: Dysphagia, mesenteric vasculitis, peritonitis, pancreatitis, hepatitis
- Neuropsychiatric: Headache, psychosis, seizure, acute confusional states, peripheral or cranial neuropathy, transverse myelitis, stroke (may be associated with antiphospholipid syndrome), cognitive dysfunction
- Hematologic (about 50% of lupus patients): Anemia (hemolytic, anemia of chronic disease, aplastic anemia), thrombocytopenia, leukopenia, lymphadenopathy, secondary antiphospholipid antibody syndrome
- Renal: Acute renal failure, proteinuria, nephritic syndrome, nephrotic syndrome

ETIOLOGY

Lupus may develop in genetically susceptible individuals, triggered by endogenous and exogenous factors. SLE susceptibility involves MHC class II polymorphism with commonly observed association with *HLA-DR-2, DR3, DR4,* and *DR8.* SLE is also associated with inherited deficiencies of C1q, C2, C4a, others. There is predilection for familial clustering of SLE with risk in monozygotic twins—about 25% to 50%—and 5% in dizygotic twins. Environmental factors such as UV light, Epstein-Barr virus infection, and tobacco smoking may have a triggering role. Autoantibody production is the hallmark of disease development and diagnosis of SLE. Evidence supports the improper processing of nuclear proteins and nucleic acid from cell death. Impairments in neutrophil cell death via a process termed NET-osis (nuclear extracellular trap) contribute to the accumulation of nuclear debris. This, in turn, can lead to the presentation of self-nuclear material to plasmacytoid dendritic cells. Plasmacytoid dendritic cells propagate antibody and immune complex production via a type I interferon-dependent mechanism.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rheumatoid arthritis, mixed connective tissue disease, systemic vasculitis
- Neoplastic disorder
- Hematologic malignancy, paraneoplastic syndrome
- Systemic infection
- Other: Thrombotic thrombocytopenic purpura/hemolytic uremic syndrome, primary antiphospholipid antibody syndrome

EVALUATION

The diagnosis of SLE is clinical. The 2019 European League Against Rheumatism/American College of Rheumatology (ACR) classification criteria for SLE include positive antinuclear antibody (ANA) at least once as obligatory entry criterion, followed by additive weighted criteria grouped in 7 clinical (constitutional, hematologic, neuropsychiatric, mucocutaneous, serosal, musculoskeletal, renal) and 3 immunologic (antiphospholipid antibodies, complement proteins, SLE-specific antibodies) domains, and weighted from 2 to 10. Patients accumulating ≥10 points are classified as having systemic lupus. The new criteria had a sensitivity of 96.1% and specificity of 93.4%, compared with 82.8% sensitivity and 93.4% specificity of the ACR 1997 (see below) and 96.7% sensitivity

TABLE 1 Potential Clinical Manifestations of Systemic Lupus Erythematosus

Target Organ	Potential Clinical Manifestations
Constitutional	Fatigue, anorexia, weight loss, fever, lymphadenopathy
Musculoskeletal	Arthritis, myositis, arthralgias, myalgias, avascular necrosis, osteoporosis
Skin	Malar rash, discoid rash, photosensitive rash, cutaneous vasculitis, livedo reticularis, periungual capillary abnormalities, Raynaud phenomenon, alopecia, oral and nasal ulcers
Renal	Hypertension, proteinuria, hematuria, edema, nephrotic syndrome, renal failure
Cardiovascular	Pericarditis, myocarditis, conduction system abnormalities, Libman-Sacks endocarditis
Neurologic	Seizures, psychosis, cerebritis, stroke, transverse myelitis, depression, cognitive impairment, headaches, pseudotumor, peripheral neuropathy, chorea, optic neuritis, cranial nerve palsies
Pulmonary	Pleuritis, interstitial lung disease, pulmonary hemorrhage, pulmonary hypertension, pulmonary embolism
Hematologic	Immune-mediated cytopenias (hemolytic anemia, thrombocytopenia or leukopenia), anemia of chronic inflammation, hypercoagulability, thrombocytopenic thrombotic microangiopathy
Gastroenterology	Hepatosplenomegaly, pancreatitis, vasculitis affecting bowel, protein-losing enteropathy
Ocular	Retinal vasculitis, scleritis, episcleritis, papilledema

and 83.7% specificity of the Systemic Lupus International Collaborating Clinics 2012 criteria.

1997 ACR Criteria:

- Malar rash
- Discoid rash
- Photosensitivity (recurrence of unusual skin rash in sun-exposed areas)
- Oral or nasopharyngeal painless ulceration, observed by physician
- Arthritis (nonerosive)
- Serositis (pleuritis, pericarditis)
- Renal disorder (persistent proteinuria >0.5 g/day, or ≥3+ on dipstick if quantification not performed; cellular casts)
- Neurologic disorder (seizures, psychosis [in absence of offending drugs or metabolic derangement])
- Hematologic disorder:
  1. Hemolytic anemia with reticulocytosis
  2. Leukopenia (<4000/mm^3 total on two or more occasions)
  3. Lymphopenia (<1500/mm^3 on two or more occasions)
  4. Thrombocytopenia (<100,000/mm^3 in the absence of offending drugs)
- Immunologic disorder:
  1. Anti–double-stranded DNA antibody (anti-dsDNA)
  2. Anti-Smith antibody (anti-Sm)
  3. Antiphospholipid antibodies (anticardiolipin IgM or IgG, lupus anticoagulant, anti-beta-2 glycoprotein IgM or IgG, or false-positive fluorescent treponemal antibody absorption test or *Treponema pallidum* immobilization for 6 months)
- ANA: An abnormal titer of ANA by immunofluorescence or equivalent assay at any time in the absence of drugs known to be associated with drug-induced lupus syndrome

2012 SLICC Criteria: SLE can be diagnosed if:

- Biopsy-proven nephritis with either ANA or anti-dsDNA antibodies *or*
- Patient satisfies four clinical criteria, requiring at least one clinical and at least one immunologic criterion
- Clinical criteria:
  1. Acute cutaneous lupus (malar rash, bullous lupus, toxic epidermal necrolysis, photosensitive lupus rash, maculopapular lupus, subacute cutaneous lupus)
  2. Chronic cutaneous lupus (discoid, hypertrophic verrucous, panniculitis, mucosal lupus, lupus tumidus, chilblains lupus, lichen planus)
  3. Oral ulcers or nasal ulcers
  4. Nonscarring alopecia
  5. Synovitis (more than two joints or inflammatory arthralgias of more than two joints)
  6. Serositis (pleurisy for more than 1 day, pericardial pain for more than 1 day)
  7. Renal (>500 mg proteinuria/24 hr) or RBC casts)
  8. Neurologic (seizures, psychosis, mononeuritis multiplex, myelitis, peripheral or cranial neuropathy, acute confusional state)
  9. Hemolytic anemia
  10. Lymphopenia (<1000/mm^3 at least once)
  11. Thrombocytopenia (<100,000/mm^3 at least once)
- Immunologic criteria:
  1. ANA
  2. Anti-dsDNA (>2× laboratory reference range)
  3. Anti-Smith
  4. Antiphospholipid antibodies (lupus anticoagulant, RPR, anti-cardiolipin IgA, IgG, IgM, anti-β2 glycoprotein IgA, IgG, IgM)
  5. Low complement
  6. Direct Coombs test in the absence of hemolytic anemia

Definitions of SLE classification criteria are included in Table 2.

LABORATORY TESTS

Suggested initial laboratory evaluation of suspected SLE:

- ANA by immunofluorescence or similar high-quality method
  1. Complete blood count with differential, blood urea nitrogen and serum creatinine, urinalysis, ESR, PTT, complements (C3, C4)

Consider additional laboratory testing in a patient with strong suspicion for systemic lupus:

- Anti-dsDNA, anti-Smith, anti-SSA, anti-SSB, anti-RNP antibodies. Table 3 summarizes autoantibodies and clinical significance in SLE
- Lupus anticoagulant, RPR, anticardiolipin antibodies, anti-beta-2 glycoprotein

TABLE 2 Definitions of SLE Classification Criteria 2019

Criteria	Definition
Antinuclear antibodies (ANA)	ANA at a titer of ≥1:80 on HEp-2 cells or an equivalent positive test at least once. Testing by immunofluorescence on HEp-2 cells or a solid-phase ANA screening immunoassay with at least equivalent performance is highly recommended.
Fever	Temperature >38.3° C (100.9° F)
Leukopenia	White blood cell count <4,000/mm^3
Thrombocytopenia	Platelet count <100,000/mm^3
Autoimmune hemolysis	Evidence of hemolysis, such as reticulocytosis, low haptoglobin, elevated indirect bilirubin, elevated LDH, *AND* positive Coombs (direct antiglobulin) test
Delirium	Characterized by 1) change in consciousness or level of arousal with reduced ability to focus, 2) symptom development over hours to <2 days, 3) symptom fluctuation throughout the day, 4) either 4a) acute/subacute change in cognition (e.g., memory deficit or disorientation), or 4b) change in behavior, mood, or affect (e.g., restlessness, reversal of sleep/wake cycle)
Psychosis	Characterized by 1) delusions and/or hallucinations without insight and 2) absence of delirium
Seizure	Primary generalized seizure or partial/focal seizure
Non-scarring alopecia	Non-scarring alopecia observed by a clinician†
Oral ulcers	Oral ulcers observed by a clinician†
Subacute cutaneous OR discoid lupus	Subacute cutaneous lupus erythematosus observed by a clinician:† Annular or papulosquamous (psoriasiform) cutaneous eruption, usually photodistributed If skin biopsy is performed, typical changes must be present (interface vacuolar dermatitis consisting of a perivascular lymphohistiocytic infiltrate, often with dermal mucin noted). OR Discoid lupus erythematosus observed by a clinician:† Erythematous-violaceous cutaneous lesions with secondary changes of atrophic scarring, dyspigmentation, often follicular hyperkeratosis/plugging (scalp), leading to scarring alopecia on the scalp If skin biopsy is performed, typical changes must be present (interface vacuolar dermatitis consisting of a perivascular and/or periappendageal lymphohistiocytic infiltrate. In the scalp, follicular keratin plugs may be seen. In longstanding lesions, mucin deposition may be noted.)
Acute cutaneous lupus	Malar rash or generalized maculopapular rash observed by a clinician† If skin biopsy is performed, typical changes must be present (interface vacuolar dermatitis consisting of a perivascular lymphohistiocytic infiltrate, often with dermal mucin noted. Perivascular neutrophilic infiltrate may be present early in the course.)
Pleural or pericardial effusion	Imaging evidence (such as ultrasound, x-ray, CT scan, MRI) of pleural or pericardial effusion, or both
Acute pericarditis	≥2 of 1) pericardial chest pain (typically sharp, worse with inspiration, improved by leaning forward), 2) pericardial rub, 3) EKG with new widespread ST elevation or PR depression, 4) new or worsened pericardial effusion on imaging (such as ultrasound, x-ray, CT scan, MRI)

TABLE 2 Definitions of SLE Classification Criteria 2019—cont'd

Criteria	Definition
Joint involvement	Either 1) synovitis involving 2 or more joints characterized by swelling or effusion, or 2) tenderness in 2 or more joints and at least 30 minutes of morning stiffness
Proteinuria >0.5 g/24 hours	Proteinuria >0.5 g/24 hours by 24-hour urine or equivalent spot urine protein-to-creatinine ratio
Class II or V lupus nephritis on renal biopsy according to ISN/RPS 2003 classification	Class II: Mesangial proliferative lupus nephritis: purely mesangial hypercellularity of any degree or mesangial matrix expansion by light microscopy, with mesangial immune deposit. A few isolated subepithelial or subendothelial deposits may be visible by immunofluorescence or electron microscopy, but not by light microscopy. Class V: Membranous lupus nephritis: global or segmental subepithelial immune deposits or their morphologic sequelae by light microscopy and by immunofluorescence or electron microscopy, with or without mesangial alterations
Class III or IV lupus nephritis on renal biopsy according to ISN/RPS 2003 classification	Class III: Focal lupus nephritis: Active or inactive focal, segmental, or global endocapillary or extracapillary glomerulonephritis involving <50% of all glomeruli, typically with focal subendothelial immune deposits, with or without mesangial alterations Class IV: Diffuse lupus nephritis: Active or inactive diffuse, segmental, or global endocapillary or extracapillary glomerulonephritis involving ≥50% of all glomeruli, typically with diffuse subendothelial immune deposits, with or without mesangial alterations. This class includes cases with diffuse wire loop deposits but with little or no glomerular proliferation.
Positive antiphospholipid antibodies	Anticardiolipin antibodies (IgA, IgG, or IgM) at medium or high titer (>40 APL, GPL, or MPL, or >the 99th percentile) or positive anti-β_2GPI antibodies (IgA, IgG, or IgM) or positive lupus anticoagulant
Low C3 OR low C4	C3 OR C4 below the lower limit of normal
Low C3 AND low C4	Both C3 AND C4 below their lower limits of normal
Anti-dsDNA antibodies OR anti-Sm antibodies	Anti-dsDNA antibodies in an immunoassay with demonstrated ≥90% specificity for SLE against relevant disease controls OR anti-Sm antibodies

anti-β_2GPI, Anti–β_2-glycoprotein I; *anti-dsDNA,* anti-double-stranded DNA; *CT,* computed tomography; *EKG,* electrocardiography; *ISN,* International Society of Nephrology; *LDH,* lactate dehydrogenase; *MRI,* magnetic resonance imaging; *RPS,* Renal Pathology Society; *SLE,* systemic lupus erythematosus.
†This may include physical examination or review of a photograph.

TABLE 3 Autoantibodies and Clinical Significance in Systemic Lupus Erythematosus (SLE)

Autoantibody	Prevalence in SLE	Clinical Significance
Antinuclear Antibody		
Anti-dsDNA	60%	95% specificity for SLE; fluctuates with disease activity; associated with glomerulonephritis
Anti-Smith	20%-30%	99% specificity for SLE; associated with anti-U1RNP antibodies
Anti-U1RNP	30%	Antibody associated with mixed connective tissue disease and lower frequency of glomerulonephritis
Anti-Ro/SSA	30%	Associated with Sjögren syndrome, photosensitivity, SCLE, neonatal lupus, congenital heart block
Anti-La/SSB	20%	Associated with Sjögren syndrome, SCLE, neonatal lupus, congenital heart block, anti-Ro/SSA
Antihistone	70%	Also associated with drug-induced lupus
Antiphospholipid	30%	Associated with arterial and venous thrombosis, pregnancy morbidity

Anti-dsDNA, Anti-double-stranded deoxyribonucleic acid; *SSA,* Anti-Sjögren-syndrome-related antigen A; *SSB,* Anti-Sjögren-syndrome-related antigen B; *SCLE,* subacute cutaneous lupus erythematosus.

antibodies especially in patients with thrombotic events or recurrent miscarriages
- Urinalysis for RBC, cellular casts
- Random spot urine protein: Urine creatinine ratio, 24-hr urine protein collection if proteinuria; >0.5 or >500 mg/24 hr is abnormal, respectively. Evaluation of renal biopsy specimens in lupus nephritis is summarized in Table 4.
- Direct Coombs test

IMAGING STUDIES

- Chest x-ray for evaluation of pulmonary involvement (pleural effusion, infiltrates)
- Electrocardiogram for chest pain
- Echocardiogram if murmur, evidence of new or unexplained congestive heart failure, or suspected pericarditis

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of sunlight and use of high-SPF sunscreen (>35).
- Screening and counseling for modifiable cardiovascular risk factors such as cigarette smoking, diet, exercise, cholesterol, and uncontrolled HTN.
- Counseling for pregnancy planning for patients of childbearing age.
- Calcium and vitamin D supplementation for prevention of early osteoporosis (see "Clinical Pearls").

GENERAL Rx

- There are only four FDA-approved SLE medications: aspirin, steroids, hydroxychloroquine (1955), and belimumab (2011).
- Treatment should be targeted toward the involved organ(s).
- Limited and defined courses of corticosteroids are useful for a variety of SLE symptoms. Steroid therapy should be restricted to acute or subacute control of symptoms, due to the increased cardiovascular risk and increased organ damage associated with chronic steroid use.
- Consider checking G6PD in certain ethnic groups more predisposed to antimalarial-induced hemolytic anemia.
- Hydroxychloroquine has best evidence for reducing flares, organ damage, lipids, thrombosis; improving survival; augmenting action of mycophenolate mofetil (MMF) in lupus nephritis; and preventing seizures. Currently recommend not to exceed dose of 5 mg/kg/day to decrease risk of retinal toxicity.
- Methotrexate and azathioprine are used as steroid-sparing agents. Indications include cutaneous and joint involvement.
- Joint pain and mild serositis are generally well controlled with NSAIDs or low-dose corticosteroids. Hydroxychloroquine and methotrexate are also effective for arthritis. Belimumab does well for joint and cutaneous manifestations. Leflunomide and rituximab may be considered for refractory arthritis. Treatment approach for musculoskeletal features of SLE is summarized in Table 5.

- Cutaneous manifestations:
  1. Topical or intradermal corticosteroids are helpful for individual discoid lesions, especially in the scalp.
  2. Hydroxychloroquine alone or in combination with quinacrine and/or chloroquine can be considered for refractory skin disease.
  3. Refractory cases may be treated with belimumab, MMF, dapsone, or combination treatment.
  4. Table 6 summarizes general management of cutaneous lesions in SLE.
- Hematologic manifestations:
  1. Corticosteroids are first-line therapy. Table E7 summarizes the treatment and main hematologic features of SLE.
  2. Azathioprine can be used for thrombocytopenia or hemolytic anemia. Check for TPMT genetic mutation before the first use.
  3. Intravenous immunoglobulin (IVIG) or rituximab may be considered for severe leukopenia, autoimmune hemolytic anemia, or autoimmune thrombocytopenia.
- Central nervous system manifestations:
  1. Headaches are treated symptomatically. Most headaches will not be SLE-related and should be treated according to underlying cause.
  2. Anticonvulsants and antipsychotics may be indicated.
  3. Standard therapy for other neuropsychiatric SLE symptoms is not established.
- Renal disease: The histologic classification of lupus nephritis according to the International Society of Nephrology/Renal Pathology Society is summarized in Table E8. Severity of lupus nephritis is described in Table E9. Treatment recommendations for lupus nephritis are summarized in Table E10. (Class III, IV or IV/V with cellular crescents lupus nephritis; see Table 11). INDUCTION: 6-mo treatment
- The typical treatment induction period is 6 months. The use of intravenous cyclophosphamide (CYC) with corticosteroids given at monthly intervals is more effective in preserving renal function than is treatment with glucocorticoids alone. Low-dose "Euro-Lupus" protocol may be equally efficacious and less toxic for certain populations (e.g., Caucasians) than high-dose regimen. MMF is considered equivalent to CYC based on high-quality studies, with better tolerability and fertility profile. MMF may be preferred in African Americans and Hispanics. MMF and azathioprine are good options for maintenance treatment.
- Severe nonrenal organ disease:
  1. Evidence from systematic randomized controlled trials for nonrenal lupus treatment is comparatively limited.
  2. High-dose intravenous CYC is used as induction treatment. Azathioprine or MMF may be used as maintenance.
  3. IVIG may be considered in severe disease especially when concomitant infection is present.
  4. Plasmapheresis or plasma exchange may be considered in critical situations: First-line therapy in Guillain-Barré syndrome, TTP, second line for SLE-related hemolytic anemia, cerebritis, and DAH. Infectious complications are common.
- Therapy targeting B cells:
  1. Rituximab: Anti-CD 20 monoclonal antibody. Randomized controlled trials for rituximab as an adjunct induction agent were negative in terms of both renal and nonrenal outcomes but were felt to be limited by study design. Some observational studies have shown efficacy in those who have failed other regimens.
  2. Epratuzumab: An anti-CD 22 agent. Studies initially showed positive data, but in July 2015 both phase III trials for SLE failed to meet their primary endpoint and this medication is no longer studied.
  3. Belimumab: Decreases activation of B cells. When used in addition to standard therapy, patients on belimumab showed improvement in cutaneous and musculoskeletal disease. Belimumab-treated patients had decreased SLE activity, a reduced time to disease flare, and lower glucocorticoid exposure. Safety data were good. Patients with central nervous system or serious kidney disease were excluded.
  4. Abatacept: Downregulates T cell activation. Data is limited regarding improvement in arthritis, fatigue, sleep if added to routine therapy. Negative data as adjunct agent for lupus arthritis when added to MMF or CYC.
  5. Interferon therapy: Interferon α (INFα) has been linked to increased disease activity in SLE. INFα blocking therapies are in phase II clinical trials. Sifalimumab, a monoclonal antibody against INFα, reduced moderate to severe mucocutaneous involvement in SLE and decreased active joint count and fatigue scores in preliminary data analysis. Development of sifalimumab has been terminated in favor of anifrolumab, a similar INFα blocking agent.
  6. There is continuous interest in studying B cell- and interferon-based treatment, but no FDA approved treatment, other than above, is currently used clinically. Novel

TABLE 4 Evaluation of Renal Biopsy Specimens in Lupus Nephritis

Renal biopsy parameters	Evaluation
Ensure that sample is adequate	Specimens with <10 glomeruli are suboptimal.
Light microscopy stains	*Hematoxylin and eosin:* Best to identify inflammatory cells
	Trichrome (Masson): Best for interstitial fibrosis, glomerulosclerosis
	Periodic acid–Schiff (PAS): Identify basement membrane abnormalities
Immunofluorescence studies	Useful for identification of immune deposits
Electron microscopy	Helps to define distribution (subendothelial, epithelial, membranous deposits) of immune complexes and detection of podocytopathy
Activity and chronicity indexes	Useful in organizing renal biopsy report as a complement to ISN/RPS 2003 classification
Important elements to consider	Activity index (especially crescents, fibrinoid necrosis)
	Chronicity index (especially interstitial fibrosis, tubular atrophy, glomerular sclerosis)
	Renal vascular lesions (related to presence of antiphospholipid antibodies)

TABLE 11 Severity of Lupus Nephritis*

Proliferative Disease	
Mild	Type III without severe histologic features (e.g., crescents, fibrinoid necrosis); low chronicity index (i.e., ≤3); normal renal function; nonnephrotic-range proteinuria
Moderately severe	Mild disease as defined above with partial or no response after the initial induction therapy or delayed remission (>12 months), or focal proliferative nephritis with adverse histologic features or reproducible increase of at least 30% in serum creatinine levels, or diffuse proliferative nephritis (class IV) without adverse histologic features
Severe	Moderately severe as defined above but not remitting after 6 to 12 mo of therapy, or proliferative disease with impaired renal function and fibrinoid necrosis or crescents in >25% of glomeruli, or mixed membranous and proliferative nephritis, or proliferative nephritis with high chronicity alone or in combination with high activity (chronicity index >4 or chronicity index >3 and activity index >10), or rapidly progressive glomerulonephritis (doubling of serum creatinine within 2 to 3 mo)
Membranous Nephropathy	
Mild	Nonnephrotic-range proteinuria with normal renal function
Moderate	Nephrotic-range proteinuria with normal renal function at presentation
Severe	Nephrotic-range proteinuria with impaired renal function at presentation (at least 30% increase in serum creatinine)

*Concomitant therapy with corticosteroids or other immunosuppressive drugs may modify urinary sediment and/or histologic findings and should be taken into consideration.
From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

potential targeted treatment approaches may include blocking IL17, IL12/23 and JAK. Research remains very active and ongoing to find new therapeutic targets.

- Recommended assessment and monitoring of patients with SLE with nonrenal, noncentral nervous system manifestations are summarized in Box 1.

DISPOSITION

- Most patients with SLE experience remissions and exacerbations.
- Five-yr survival rate has improved to more than 90% in patients with newly diagnosed SLE since the advent of potent immunosuppressive therapy. The 15-yr survival rate is now 85%.
- Early death related to SLE activity and infections; late death due to CVD.
- Lupus nephritis progression rate to ESRD in 10% to 30% within 15 yr.
- African Americans, Asian Americans, and Hispanic Americans in general have a worse prognosis. The leading cause of death in SLE patients in developed countries is premature atherosclerosis. The quality of life for many SLE patients is poor due to fatigue, chronic pain, and cognitive impairment.

REFERRAL

- Rheumatology consultation for all patients with SLE
- Hematology consultation for patients with significant hematologic abnormalities (e.g., severe hemolytic anemia or thrombocytopenia)

BOX 1 Recommended Assessment and Monitoring of Patients with Systemic Lupus Erythematosus with Nonrenal, Non-Central Nervous System Manifestations

Patient general assessment
In addition to the standard care of patients without lupus of the same age and sex, the assessment of patients with SLE must include the evaluation of:
- Disease activity by a validated index at each visit
- Organ damage annually
- General quality of life by patient history and/or by a 0–10 VAS (patient global score) at each visit
- Comorbidities
- Drug toxicity

Cardiovascular risk factors
At baseline and during followup at least once a year:
- Assess smoking, vascular events (cerebral and cardiovascular), physical activity, oral contraceptives, hormonal therapies, and family history of cardiovascular disease
- Perform blood tests: Blood cholesterol, glucose
- Examine for blood pressure and BMI (and/or waist circumference)
- NB: Some patients may need more frequent followup (e.g., those taking glucocorticoids).

Osteoporosis risk
All patients with SLE:
- Should be assessed for adequate calcium and vitamin D intake, regular exercise, and smoking habits
- Should be screened and followed for osteoporosis according to existing guidelines (1) for postmenopausal women and (2) for patients taking glucocorticoids or on any other medication that may reduce BMD

Cancer risk
Cancer screening is recommended according to the guidelines for the general population, including cervical smear tests.

Infection risk
Screening: Patients with SLE should be screened for:
- HIV based on the patient's risk factors
- HCV and HBV based on the patient's risk factors, particularly before IS drugs including high-dose glucocorticoids are given
- Tuberculosis, according to local guidelines, especially before IS drugs including high-dose glucocorticoids are given
- CMV testing should be considered during treatment in selected patients.

Vaccination: Patients with SLE are at high risk of infections, and prevention should be recommended. The administration of inactivated vaccines (especially flu and pneumococcus), following CDC guidelines for patients who are immunosuppressed, should be encouraged strongly in patients with SLE who take IS drugs, preferably administered when the SLE is inactive. For other vaccinations, an individual risk–benefit analysis is recommended.

Monitoring: At followup visits, continuous assessment of the risk of infection by taking into consideration the presence of:
- Severe neutropenia (<500 cells/mm^3)
- Severe lymphopenia (<500 cells/mm^3)
- Low IgG (<500 mg/dL)

Frequency of assessments
In patients with no activity, no damage, and no comorbidity, assessments are recommended every 6 to 12 months. During these visits, preventive measures should be emphasized.

Laboratory assessment
It is recommended to monitor the following autoantibodies and complement:
- At baseline: ANA, anti-dsDNA, anti-Ro, anti-La, anti-RNP, anti-Sm, antiphospholipid, C3, C4
- Reevaluation of aPLs in previously negative patients before pregnancy, surgery, transplant, and use of estrogen-containing treatments or in the presence of a new neurologic or vascular event; anti-Ro and anti-La antibodies before pregnancy; anti-dsDNA/C3 C4 may support evidence of disease activity or remission

Other laboratory assessments. At 6- to 12-month intervals, patients with inactive disease should have:
- CBC
- ESR
- CRP
- Serum albumin
- Serum creatinine (or eGFR)
- Urinalysis and urine protein-to-creatinine ratio

NB: If a patient is on a specific drug treatment, monitoring for that drug is required as well.

Mucocutaneous involvement
Mucocutaneous lesions should be characterized, according to existing classification systems, as to whether they may be:
- LE specific
- LE nonspecific
- LE mimickers
- Drug-related

Lesions should be assessed for activity and damage using validated indices (e.g., CLASI).

Eye assessment
In patients treated with glucocorticoids or antimalarials, a baseline eye examination is recommended according to standard guidelines. An eye examination during followup is recommended:
- In selected patients taking glucocorticoids (high risk of glaucoma or cataracts)
- In patients on antimalarial drugs. (Low risk: HCQ: No further testing is required until after 5 years of baseline, and after the first 5 years of treatment, eye assessment is recommended yearly; High risk: Eye assessment is recommended yearly, especially when using CQ).

ANA, Antinuclear antibodies; *aPL,* antiphospholipid antibody; *BMD,* bone mineral density; *BMI,* body mass index; *CBC,* complete blood count; *CDC,* Centers for Disease Control and Prevention; *CLASI,* Cutaneous Lupus Erythematosus Disease Area and Severity Index; *CMV,* cytomegalovirus; *CQ,* chloroquine; *CRP,* C-reactive protein; *eGFR,* estimated glomerular filtration rate; *ESR,* erythrocyte sedimentation rate; *HBV,* hepatitis B virus; *HCQ,* hydroxychloroquine; *HCV,* hepatitis C virus; *IgG,* immunoglobulin G; *IS,* immunosuppressors; *LE,* lupus erythematosus; *NB,* nota bene; *SLE,* systemic lupus erythematosus; *VAS,* visual analog scale.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

- Nephrology consultation in patients with proteinuria and/or suspected renal involvement
- Dermatology consultation for patients with unexplained or unusual skin rash
- Cardiology consultation for patients with lupus carditis, arrhythmias
- Ophthalmology referral for all patients on hydroxychloroquine and chloroquine

PEARLS & CONSIDERATIONS

- Arthritis in SLE often has no prolonged morning stiffness and is not erosive on x-rays; reversible joint deformities in lupus are termed Jaccoud arthropathy.
- Myocardial infarction is 50 times more common in young female patients than in age-matched control group.
- Prevent adverse effects of medications: Consider prophylaxis for infections and appropriate vaccinations, ensure yearly Pap and other cancer screening as clinically indicated; for patients taking CYC, intervention to preserve bladder and fertility should be considered; manage bone health.
- Based on small clinical data a vitamin D level >40 may have modest reduction in disease activity; in addition vitamin D may reduce risk of thrombosis, based on oncology research.

TABLE E8 Histologic Classification of Lupus Nephritis According to the International Society of Nephrology/Renal Pathology Society (2003)

Class	Description
I	Minimal mesangial lupus nephritis
	Normal glomeruli by light microscopy, but mesangial immune deposits by immunofluorescence
II	Mesangial proliferative lupus nephritis
	Purely mesangial hypercellularity of any degree or mesangial matrix expansion by light microscopy, with mesangial immune deposits
	A few isolated subepithelial or subendothelial deposits may be visible by immunofluorescence or electron microscopy but not by light microscopy
III	Focal lupus nephritis
	Active or inactive focal, segmental, or global endocapillary or extracapillary glomerulonephritis involving <50% of all glomeruli, typically with focal subendothelial immune deposits, with or without mesangial alterations
IV	Diffuse lupus nephritis
	Active or inactive diffuse, segmental, or global endocapillary or extracapillary glomerulonephritis involving ≥50% of all glomeruli, typically with diffuse subendothelial immune deposits, with or without mesangial alterations. This class is divided into *diffuse segmental* (IV-S) lupus nephritis when ≥50% of the involved glomeruli have segmental lesions and diffuse global (IV-G) when ≥50% of the involved glomeruli have global lesions. *Segmental* is defined as a glomerular lesion that involves less than half of the glomerular tuft. This class includes cases with diffuse wire loop deposits but with little or no glomerular proliferation.
V	Membranous lupus nephritis
	Global or segmental subepithelial immune deposits or their morphologic sequelae by light microscopy and by immunofluorescence or electron microscopy, with or without mesangial alterations
	Class V nephritis may occur in combination with class III or class IV, in which case both will be diagnosed.
	Class V nephritis may show advanced sclerotic lesions.
VI	Advanced sclerotic lupus nephritis ≥90% of the glomeruli globally sclerosed without residual activity

TABLE E10 Recommended Treatment of Lupus Nephritis

Histologic type or severity	Type of therapy	
	Induction	**Maintenance**
Proliferative		
Mild	• High-dose glucocorticoids (0.5-1 mg/kg/day for 4-6 wk with gradual tapering to 0.125 mg/kg every other day within 3-4 mo) alone or in combination with AZA (1-2 mg/kg/day) • If no response within 3-6 mo, treat as moderately severe.	• Low-dose glucocorticoids (≤0.125 mg/kg on alternative days) alone or with AZA (1-2 mg/kg/day) • Consider further gradual tapering at the end of each year of response.
Moderate	• MPA (MMF 3 g/day) with glucocorticoids (0.5 mg/kg/day for 4 wk; then taper) for 6 mo. Consider three initial pulses of IV MP (500-750 mg/pulse), or • Pulse IV CYC (3 g over 3 mo) with glucocorticoids as above • If no response within 6-12 mo, treat as severe.	• Low-dose glucocorticoids (≤0.125 mg/kg on alternative days) with MPA (MMF 2 g/day) for 18-24 mo after initial response; then consider gradual tapering, or • AZA (2 mg/kg/day)
Severe	• Monthly pulses of IV CYC (0.5-1 g/m^2) in combination with pulse IV MP for 6 mo. Background glucocorticoids (0.5 mg/kg/day for 4 wk; then taper), or • MPA (MMF 3 g/day) • If no improvement, consider MPA, combination of MPA with calcineurin inhibitor, or rituximab.	• Low-dose glucocorticoids (≤0.125 mg/kg on alternative days) in combination with quarterly pulses of IV CYC for at least 1 yr beyond response, or • MPA (MMF 2 g/day)
Membranous		
Mild	• High-dose glucocorticoids alone or in combination with AZA (2 mg/kg/day)	• Low-dose glucocorticoids alone or with AZA (1-2 mg/kg/day)
Moderate to severe	• High-dose glucocorticoids in combination with MPA (MMF 3 g/day), or • Bimonthly pulse IV CYC (0.5-1 g/m^2, six pulses), or • CsA (3-5 mg/kg/day) or tacrolimus	• Low-dose glucocorticoids • AZA (2 mg/kg/day) • CsA (3 mg/kg/day) or tacrolimus • MPA (MMF 2 g/day)

Tabes Dorsalis

BASIC INFORMATION

DEFINITION

Tabes dorsalis is a form of late neurosyphilis affecting the dorsal columns of the spinal cord and peripheral nerves, characterized by paroxysmal pain, particularly in the abdomen and legs; sensory ataxia; normal strength; autonomic dysfunction; and Argyll Robertson pupils.

SYNONYMS

Posterior spinal sclerosis
Tabetic neurosyphilis
Syphilitic myeloneuropathy
Neurosyphilis

ICD-10CM CODE
A52.11 Tabes dorsalis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Rare, but increasing with HIV/AIDS
PEAK INCIDENCE: 15 to 20 yr after initial infection
PREVALENCE (IN U.S.): Rare; more common with HIV/AIDS epidemic. Ten percent of untreated patients with syphilis develop neurosyphilis, 2% to 5% of whom may develop tabes dorsalis. Relative prevalence of tabes dorsalis is reduced compared with the preantibiotic era. This may be the only clinical manifestation of neurosyphilis that has been altered during the antibiotic era.
PREDOMINANT SEX: Male

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Argyll Robertson pupils are common. The pupil reacts poorly to light but well to accommodation (light-near dissociation)
- Loss of position and vibration at ankles (wide-based gait, inability to walk in the dark, sensory ataxia)
- Loss of deep pain sensation, resulting in deep foot ulcers
- Degenerative joint disease (Fig. E1), especially in knees, caused by severe neuropathy (Charcot joints)
- Normal strength with areflexia in the legs
- Lightning pains in the legs
- Severe intermittent visceral pains, such as gastrointestinal and laryngeal (visceral crises)
- Autonomic dysfunction (urinary and fecal incontinence due to sphincter dysfunction)

ETIOLOGY

Infectious *(Treponema pallidum).* Neurosyphilis occurs as a consequence of treponemal penetration of the blood-brain barrier and destruction of adjacent neural tissue, sometimes coupled with cerebral infarction due to meningovascular disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vitamin B_{12} deficiency (subacute combined degeneration of the spinal cord)
- Vitamin E deficiency
- Chronic nitrous oxide abuse
- Spinal cord neoplasm (involving conus medullaris)
- Lyme disease

WORKUP

Thorough neurologic history and examination

LABORATORY TESTS

- Lumbar puncture: The diagnosis of neurosyphilis requires a CSF mononuclear pleocytosis of 20 WBC/μL or a reactive Venereal Disease Research Laboratory (VDRL) or a positive intrathecal *T. pallidum* antibody index. Pleocytosis is less specific in patients with HIV due to HIV-related meningitis.
- False-positive serum RPR may occur in Lyme disease, nonvenereal treponematoses, genital herpes simplex, pregnancy, systemic lupus erythematosus, alcoholic cirrhosis, scleroderma, and mixed connective tissue disease.
- All patients with syphilis should be tested for HIV.
- Persons who are HIV positive are at increased risk of developing neurosyphilis. A new development in the detection of neurosyphilis in patients who are HIV positive is the use of the B-cell chemoattractant chemokine (CXC motif) ligand 13 as a CSF marker.

IMAGING STUDIES

Not necessary if diagnosis confirmed clinically and serologically

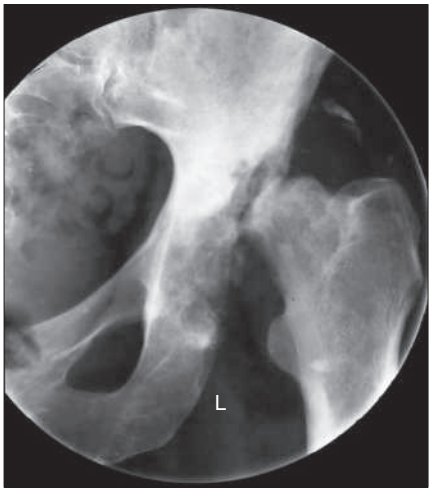

FIG. E1 Neuropathic hip secondary to tabes dorsalis. (Courtesy Dr. I. Watt. From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

TREATMENT

ACUTE GENERAL Rx

- CDC guidelines: Aqueous crystalline penicillin G 18 to 24 million units per day, administered as 3 to 4 million units IV every 4 hours, or continuous infusion for 10 to 14 days; or if adherence can be ensured, penicillin G procaine, 2.4 million units IM daily, plus probenecid 500 mg orally four times a day for 10 to 14 days
- If patient is penicillin allergic, either desensitize to penicillin or obtain an infectious disease (ID) consultation.
- Many of the symptoms—degenerative neuropathic joint disease, lightning pains—persist after treatment.

CHRONIC Rx

- Physical therapy
- Analgesics, carbamazepine, gabapentin, or steroids may help lightning pain
- Supportive care (wheelchair, toileting issues, etc.)

DISPOSITION

- Close follow-up required. Repeat lumbar puncture is recommended every 6 mo until CSF pleocytosis normalizes. If pleocytosis does not normalize in 6 mo or CSF is still abnormal in 2 yr, repeat treatment. Serologic criterion for response to therapy is a fourfold or greater decrease in VDRL titer over 6 to 12 mo.
- Further indication for retreatment: If there is a fourfold increase in titers or a failure of titers >1:32 to decrease at least fourfold by 6 to 12 mo.

REFERRAL

- Joint replacement in moderate cases
- ID consult for patients with penicillin allergy

PEARLS & CONSIDERATIONS

COMMENTS

- Diagnosis should be considered in all patients with a progressive neuropsychiatric disorder with signs of spinal cord dysfunction and peripheral neuropathy.
- Penicillin does not improve late neurosyphilitic syndromes but usually halts their progression.

BASIC INFORMATION

DEFINITION

Takayasu arteritis is a large-vessel vasculitis that primarily affects the aorta and its main branches. Chronic inflammation of involved vessels commonly leads to stenosis, occlusion, dilation, and aneurysms in the arterial wall.

SYNONYMS

Pulseless disease
Aortitis syndrome
Aortic arch arteritis
Nonspecific aortoarteritis

ICD-10CM CODE
M31.4 Aortic arch syndrome [Takayasu]

EPIDEMIOLOGY & DEMOGRAPHICS

In the U.S., the incidence is 2.6 per 1 million people. The highest prevalence of Takayasu arteritis has been described in Japan, where all cases of Takayasu arteritis are registered by the government, and it has been estimated that 100 to 200 new cases occur each yr.

The female:male ratio is 8:1. Age of onset is between 10 and 40 yr with three quarters of patients presenting between the ages of 10 and 20 yr.

GENETICS: Some HLA alleles, including HLA-B52, HLA-B39, and HLA-B67, have been reported to be associated with Takayasu.

CLINICAL PRESENTATION & PHYSICAL FINDINGS

Takayasu arteritis manifests with clinically nonspecific signs and symptoms of systemic inflammation, including general fatigue, weight loss, generalized arthralgias and myalgias, and low-/high-grade fever. These symptoms are usually subacute, which leads to delay in the diagnosis from mos to yrs. Vascular symptoms are rare at presentation, and localized symptoms and signs vary depending on the location of the affected arteries.

- Table E1 summarizes common symptoms and signs in Takayasu arteritis. "Red flags" for Takayasu arteritis are summarized in Table E2.
- The occlusive stage of Takayasu arteritis may progress to stenosis or aneurysm of the aorta and its primary branches, and may manifest as a variety of clinical signs and symptoms, such as:
  1. Arm or leg claudication, weakness, and numbness
  2. Amaurosis fugax, diplopia, headache, orthostasis, vertigo, memory loss, or syncope
  3. Angina or myocardial infarction
  4. Vascular bruits of the carotid artery, subclavian artery, and aorta
  5. Discrepancy of blood pressures between the upper extremities, typically of ≥10 mm Hg
  6. Diminished or absent pulses, ischemic ulcerations, or gangrene in advanced disease
  7. Hypertension
  8. Retinopathy
  9. Aortic insufficiency as a result of aortic root dilatation and aneurysm formation
  10. Weakness of the arterial walls may give rise to localized aneurysms/dissection.
  11. Dyspnea or hemoptysis
  12. Skin lesions similar to erythema nodosum
- Gastrointestinal (GI) symptoms (abdominal pain, diarrhea, and GI bleed) secondary to mesenteric artery ischemia

ETIOLOGY & PATHOGENESIS

The cause of Takayasu arteritis is poorly understood. Cell-mediated mechanisms (cytotoxic T cell, macrophage, natural killer cells, and others) and cytokine release (such as tumor necrosis factor-alpha [TNF-α], interleukin-6 [IL-6], and interferon-gamma [IFN-γ]) are thought to be important to the pathogenesis. Both pathways contribute to the induction and amplification of inflammation and tissue injury.

- Infiltration by inflammatory cells (lymphocytes, macrophages, and multinucleated giant cells) into the vasa vasorum and media of the large elastic arteries (Fig. E1) leads to production of matrix metalloproteinases (MMP), which cause destruction of elastic fibers in the arterial wall, neovascularization, and other inflammatory changes. An intermediate stage, driven in part by TNF-alpha, leads to mucopolysaccharide deposition and proliferation of fibroblasts and smooth muscle cells, causing intimal hypertrophy.
- With chronic disease, inflammatory lesions progress to either thick fibrotic calcified narrowings (≥90% of cases) or aneurysms if fibrosis is insufficient and the arterial wall is instead thinned and dilated (≥25% of cases).
- Infection, in particular, tuberculosis, has been implicated in the pathogenesis, with several studies reporting an increased incidence of caseating granulomas in patients with Takayasu arteritis. Additional immunologic studies lend support to a pathogenic role of CD4 and CD8 T cells in this patient population.

DIAGNOSIS

Diagnostic criteria for Takayasu arteritis were established by the American College of Rheumatology in 1990. A diagnosis is made if at least three of the six criteria are present; this

TABLE E1 Common Symptoms and Signs (%) in Takayasu Arteritis

	Study					
Symptom/Sign	**Japan (n = 52)**	**India (n = 106)**	**China (n = 530)**	**Korea (n = 129)**	**U.S. (n = 60)**	**Mexico (n = 107)**
Fatigue/constitutional	27%	—	—	34%	43%	78%
Weight loss	—	9%	—	11%	20%	22%
Musculoskeletal	6%	5%	—	—	53%	53%
Claudication	13%	—	25%	21%	90%	29%
Headache	31%	44%	—	60%	42%	57%
Visual changes	6%	12%	10%	20%	30%	8%
Syncope/dizziness	40%	26%	14%	36%	35%	13%
Palpitations	23%	19%	—	23%	10%	43%
Dyspnea	21%	26%	11%	42%	—	72%
Carotidynia	21%	—	—	2%	32%	—
Hypertension	33%	77%	60%	40%	35%	72%
Bruit	—	35%	58%	37%	80%	94%
Decreased pulses	62%	—	37%	55%	60%	96%
Asymmetric blood pressure	—	—	—	—	47%	—

From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

results in a sensitivity of 91% and specificity of 98%. The criteria are:

- Age of disease onset <40 yr
- Claudication of the extremities
- Decreased brachial artery pulse
- Systolic blood pressure difference ≥10 mm Hg between left and right arms

TABLE E2 "Red Flags" for Takayasu Arteritis

In patients younger than 40 yr, the following may be indicative of TA:
Unexplained acute-phase response (raised ESR and/or CRP)
Carotidynia
Hypertension
Discrepant blood pressure between the arms (>10 mm Hg)
Absent or weak peripheral pulse or pulses
Limb claudication
Arterial bruit
Angina

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

- Bruit over one or both of the subclavian arteries or the abdominal aorta
- Abnormal arteriogram, not related to arteriosclerosis or fibromuscular dysplasia

DIFFERENTIAL DIAGNOSIS

Table E3 describes pathologic characteristics of selected forms of vasculitis. Other causes of inflammatory arteritis must be excluded:

- Temporal arteritis (giant cell arteritis)
- Atherosclerosis
- Infectious aortitis
- Syphilis
- Tuberculosis
- Systemic lupus erythematosus
- Rheumatoid arthritis
- Buerger disease
- Behçet disease
- Marfan syndrome
- Ehlers-Danlos syndrome

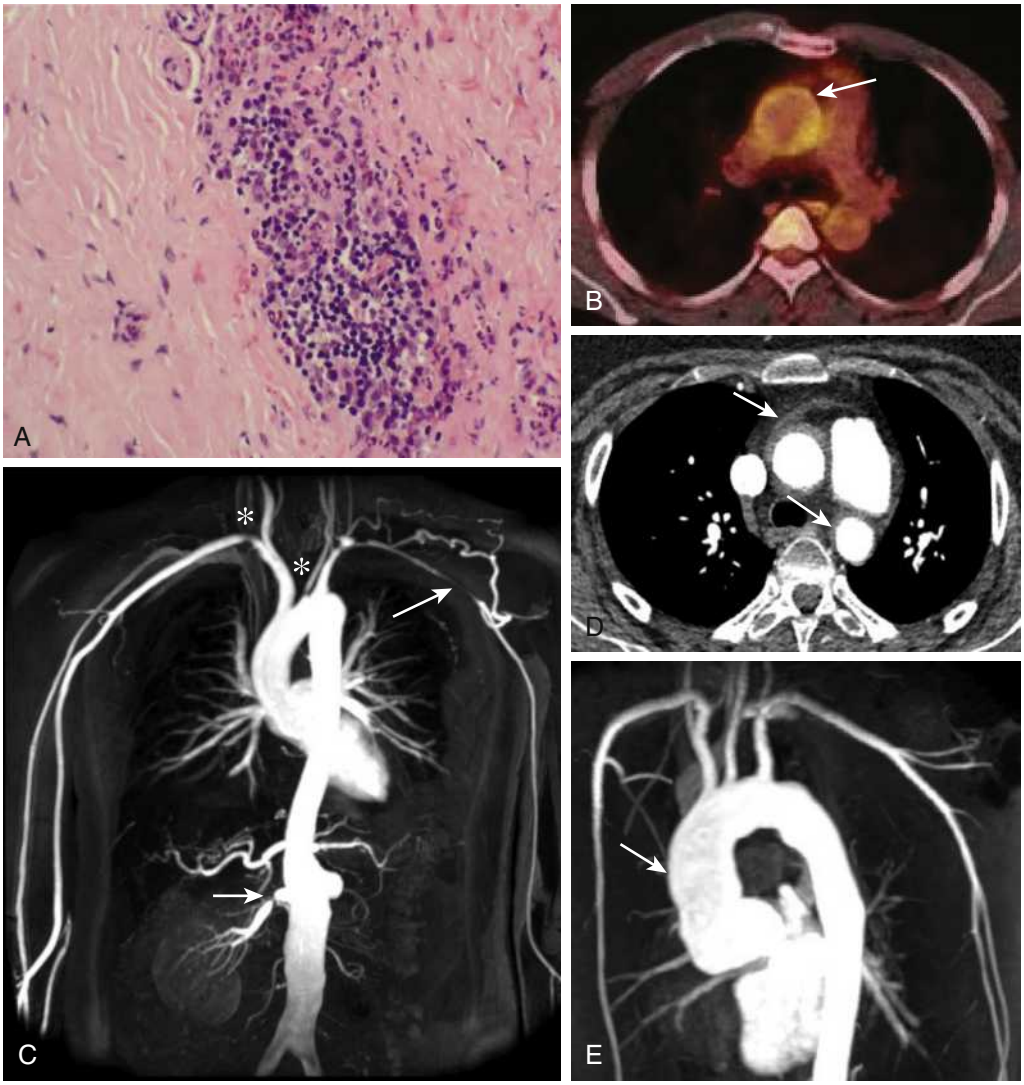

FIG. E1 Takayasu arteritis A, Hematoxylin-eosin staining of a common carotid artery biopsy specimen obtained at surgery shows a focal mixed mononuclear cell inflammatory infiltrate with a multinucleated giant cell. **B,** ^{18}FDG-PET-CT scan demonstrating uptake in the aortic arch *(arrow)*, consistent with active arteritis. **C,** Magnetic resonance angiogram (MRA) demonstrating stenosis of the left subclavian artery with collateral formation *(long arrow)*, proximal stenoses in the right subclavian and left common carotid arteries *(stars)*, proximal stenosis in the right renal artery *(short arrow)*, and an atrophic left kidney. **D,** Computed tomography angiogram demonstrating thickening of the wall of the ascending and descending aorta *(arrows).* **E,** MRA revealing severe dilatation of the ascending aorta *(arrow)* requiring aortic valve replacement. (Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

- Cogan syndrome
- Kawasaki disease
- Spondyloarthropathies
- Fibromuscular dysplasia
- Relapsing polychondritis

WORKUP

Any young patient with findings of absent pulses and loud bruits merits a workup for Takayasu arteritis. There are no diagnostic laboratory tests to diagnose Takayasu arteritis. Nonspecific inflammatory biomarkers, including C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR), are useful markers for diagnosis, but normal values shouldn't be used to rule out the disease. In most patients, the diagnosis is made by clinical findings and imaging of the arterial branches. Advanced imaging modalities, including contrast-enhanced magnetic resonance angiography (MRA) and computed tomography angiography (CTA), allow for not only early diagnosis but also detailed assessment of vascular lesions. Three-dimensional reconstructions of the whole aorta and neck arteries using CTA are especially useful for surveying lesions. Ultrasound and FDG-PET are commonly used for diagnosis as well as in serial monitoring of disease activity. Catheter-based angiography is used to rule out ischemia and to measure core blood pressure when all four limbs arterial stenosis prevent accurate blood pressure measurement.

LABORATORY TESTS

- ESR and serum CRP levels are usually but not always elevated.
- A CBC may reveal a normal or elevated white blood cell count as well as anemia.
- Immunologic studies may include elevated immunoglobulins (IgG and IgA) and complement components (C3 and C4).
- Hypercoagulation and increase in platelet aggregation.
- Recent studies have attempted to establish a link between elevated levels of various interleukins and other inflammatory markers and active disease.

IMAGING STUDIES

- Imaging of the entire aorta and major branch vessels using angiography, CTA, or MRA.
- CTA can detect changes in the vessel wall and provide an accurate representation of luminal diameters.
- MRA provides information on vessel lumen and wall thickening, cardiac morphology and function, and myocardial tissue characterization.
- Angiography can show the narrowing of the aorta and its branches, aneurysm formation, poststenotic dilation, and the development of any collateral circulation. Angiographic findings are classified into five major types:
  1. Type I: Lesions that involve only branches of the aortic arch
  2. Type IIa: Lesions that involve the ascending aorta, the aortic arch, and its branches
  3. Type IIb: Lesions from IIa plus the thoracic descending aorta
  4. Type III: Lesions that involve the thoracic descending aorta, abdominal aorta, and/or renal arteries
  5. Type IV: Lesions that involve the abdominal aorta and/or renal arteries
  6. Type V: Lesions that involve the entire aorta and its branches
- Chest radiography: Pathologic changes of the aorta are often visible, with areas of alternating stenosis and dilation seen. Segmental calcification outlining areas of aortic narrowing is characteristic of Takayasu disease.
- Ultrasound: Carotid, thoracic, and abdominal ultrasound are useful adjunctive imaging studies to diagnose the occlusive disease that results from Takayasu arteritis. The addition of Doppler is helpful to assess blood flow and absent pulses.
- Positron emission tomography using radioisotope fluorodeoxyglucose (FDG-PET) as a marker for tissue with high glucose uptake has shown promising results in terms of specificity and sensitivity. The yield of using PET scans to measure disease activity is still under study.

Rx TREATMENT

Treatment of Takayasu arteritis consists of two parts: Induction and maintenance of remission and management of arterial complications.

ACUTE GENERAL Rx

High-dose glucocorticoids are first-line therapy for suppressing systemic symptoms and stopping disease progression. Prednisone (1 mg/kg/day, up to a maximum daily dose of 60 to 80 mg) can be used for 3 mo or intravenous steroids can be administered initially.

Attempts to taper prednisone can be made with resolution of constitutional symptoms, significant decline in the ESR and C-reactive protein levels, and in accordance with imaging studies.

Because of steroids' side effects and the high rate of relapse while tapering, it is recom-

TABLE E3 Pathologic Characteristics of Selected Forms of Vasculitis

	Takayasu Arteritis	Polyarteritis Nodosa	Wegener Granulomatosis	Churg-Strauss Syndrome	Henoch-Schönlein Purpura	Cutaneous Leukocytoclastic Angiitis
Vessels involved	Elastic (large) or muscle (medium-sized) arteries	Medium-sized and small muscle arteries	Small arteries and veins; sometimes medium-sized vessels	Small arteries and veins; sometimes medium-sized vessels	Capillaries, venules, arterioles	Capillaries, venules, arterioles
Organ involvement	Aorta, aortic arch and major branches, pulmonary arteries	Skin, peripheral nerve, gastrointestinal tract, other viscera	Upper respiratory tract, lungs, kidneys, skin, eyes	Upper respiratory tract, lungs, heart, peripheral nerves	Skin, joints, gastrointestinal tract, kidneys	Skin, joints
Type of vasculitis and inflammatory cells	Granulomatous with some giant cells; fibrosis in chronic stages	Necrotizing, with mixed cellular infiltrate	Necrotizing or granulomatous (or both); mixed cellular infiltrate plus occasional eosinophils	Necrotizing or granulomatous (or both); prominent eosinophils and other mixed infiltrate	Leukocytoclastic, with some lymphocytes and variable eosinophils; IgA deposits in affected tissues	Leukocytoclastic, with occasional eosinophils

IgA, Immunoglobulin A.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

mended to use a glucocorticoid sparing agent at the time prednisone is prescribed. Commonly used second agents include:

- Leflunomide
- Methotrexate
- Mycophenolate mofetil
- Azathioprine
- Tocilizumab
- Anti-TNF agents
- Cyclophosphamide

CHRONIC Rx
